Reverting to Remond's division into primary and secondary forces, the former play the leading part in the formation and existence of definite chemical compounds. They are distinguished from the secondary by "their greater importance" and property of saturation and of valency. The special case of carbon is briefly considered by Remond, in the formation of monomeric molecular chains. The secondary forces are those of the polymer, and obviously much weaker. He proceeds to consider some of the fundamental principles of adhesion, including artificial change of polarity, for example, by acid treatment, where this is necessary for effective adhesion, as in the case when rubber (non-polar) is to be joined to wood (polar). An interesting example is cited in the case of the manufacture of a heat exchanger by A. P. V. Co., Ltd.

A great deal of adhesion research is also proceeding in Germany, by such leading firms as Henkel and Cie., Huls, and the BASF (Badische Anilin u. Sodafab.) at Leverkusen. For the latter, Dr. H. Sonne is in charge of developments, and in reporting more particularly on work with dry (or pressure-sensitive) adhesives he has included some interesting notes on molecular structure in relation to adhesion[3]. Here again, cohesion and adhesion are both included in what presumably must be a wide interpretation of the German term *Klebfähigkeit*, or glutability. Undoubtedly, the old-fashioned term 'glue', which in the olden days meant practically only one kind of adhesive, as used by the village carpenter or handyman in his familiar glue-pot, is now applied to a vastly wider and more varied collection now that synthetic resins, and many other materials, have entered the adhesives field; but it is perhaps a little unusual to extend it so far as to include cohesion.

Dr. Sonne deals with high-molecular materials with side-valencies, in which a dispersion effect may be involved, or a disturbance, through chemical bonding, of the original natural frequency of the electron system; also, dipole effects of polar molecules may be involved (that is, an electrical moment). An accumulation of polar groups, as in long-chain molecules, must necessarily increase the total moment, and therefore also the outwardly acting forces. In the normal paraffin ($CH_2$) chain is a non-polar system of high symmetry but of low dispersion effect and relatively small outward force. But the introduction of side-groups or secondary chains causes immediately a non-symmetrical charge distribution which affects inductively the whole molecule; and this becomes more marked with increasing length of chain and number of side-groups, as in high-polymer compounds. Dr. Sonne draws the interesting distinction that "the dispersion forces of the main chain affect chiefly cohesion, while the dipole forces of the side-chains are chiefly related to adhesion". Thus, these side-chains act as innumerable 'fixing points' in the molecule.

In the manufacture of dry (pressure-sensitive) adhesives, compounds of such molecular structure are no doubt to be preferred—for example, those of the poly*iso*butylene (Oppanol *B*) and natural rubber type—as may be deduced from a consideration of their structural formulæ. Others that may be included in this category are the polyacrylates (COO*R*— side-groups), polyvinyl ethers ($OCH_3$—), polyvinyl chloride, polystyrol, Buna products, etc. All these materials have adhesive properties, actual or potential, but the relevant conditions and relations vary considerably, and are somewhat complex. Polymerizates of this kind almost invariably form isomeric mixtures, with chain structures of widely varying length and side-group. It is to be observed that the $CH_3$— side-groups are usually associated with high adhesive power, and it may reasonably be assumed that, with Buna rubbers for example, having lower adhesive powers than natural rubber, mixed polymerizates have been formed that should be of considerable interest in this connexion. Both the natural and synthetic rubber types, as regards the double bonds therein, have unique properties and failings. They are sensitive to the action of oxygen or light, with resulting changes that indicate a lack of stability prejudicial to adhesive power.

More recently, an important further contribution has been made in a symposium on the theory and practice of adhesion at a meeting of the American Chemical Society in Cincinnati (reviewed in *Chem. and Eng. News* of April 18, pp. 1639–40, under the heading, "Why does it stick?"). The symposium included papers on wettability in relation to adhesion, by W. A. Zisman (Naval Research Laboratory); an atomistic approach, by R. M. Gruver (Linden Laboratories), with a note on the electrical forces emanating from surface ions that are not completely surrounded by those of opposite charge; the failure of adhesive bonds involving passage over the free-energy barrier, and the significance of the absolute rate theory in connexion with adhesion, by Marshall R. Hatfield (3M—Minnesota Min. and Mfg. Co.); the measurement of adsorption tendencies in addition to physical test methods, by L. Reed Brantley (Occidental College); cementing various materials to glass, with particular reference to moisture resistance, by F. Moser (Pittsburgh Plate Glass Co.); epoxides and their superiority in this respect, by E. W. McGuiness (General Electric

Co.); new tool for study of structural bond breakdown, with special reference to metal/metal bonds, by S. M. Skinner (Case Institute of Technology); new apparatus for measuring adhesive bond strengths, provisionally called the 'hesiometer', by W. K. Asbeck (Carbide and Carbon Corporation).

An important contribution from the U.S.S.R. to the theory of adhesion, including claims for a new electrical theory, is to be found in a fairly long article by B. V. Deryagin[4], based on his own extensive research and that of other Soviet scientists. He observes that this subject, despite its wide and increasingly varied practical importance, has been neglected on the theoretical side. In the case of protective coatings and adhesive films, it used to be considered fairly obvious that the adhesive forces were of a molecular or chemical nature, in which the surfaces joined took part; but this did not appear consistent with actual measurements of the forces needed to tear away a film under conditions that did not greatly affect the strength of the film itself. These forces might be as much as $10^6$ or even more ergs/cm.$^2$, according to the speed of tear, and this exceeds by many times that required for breaking chemical or molecular bonds. It is necessary here to consider also the number of molecules or chemical bonds per unit surface (one must note, too, many cases of apparent chemical bonding, as in that of rubber to steel by vulcanization).

As an aid to solution, the author thinks secondary phenomena often noted in film removal may be invoked, such as luminescence and crackling, that indicate electrical discharge. On this basis, the Soviet workers claim to have founded their new electrical theory, briefly as follows: on contact of any two bodies, conductors or not, as already known, two electrical layers form at the interface, positive and negative; with some difference of potentials through transfer of charge from one phase to the other, and expenditure of work against electrical forces in the interface, as in a condenser, this difference may be a fraction of a volt to several volts.

If tear-away is sufficiently rapid and does not involve also cohesion (integrity of film itself), there should be separation at identical points of the outer zones of both electrical layers. Differences of potentials between these will depend on distance of separation, and be limited by discharge possibilities. The author here discusses at some length variations in charge according to pressure of ambient gas ($p$), the validity of the laws of gaseous discharge—including Paschen's—and other factors including ionization. If the discharge gap ($h$) or potential ($V$) is known, the following formula gives the work expended ($A$): $A = 2\pi\sigma^2/h = \sigma V/2$, where $\sigma$ is the charge density.

According to Deryagin, under the action of intensive forces of electrical attraction the electrons torn from one surface and dispersing with high energy impinge on the opposite surface, dislodging therefrom positively charged ions and also photons. There is movement towards the surface. Under the impact new secondary electrons are dislodged, and if the number of these exceeds that of the first the electrons multiply, leading to discharge. This may be further complicated in that impacts of positive ions may produce, together with electron emission, a secondary emission of negative ions and also a photo-effect. But the general mechanism and nature of the discharge are obviously not changed as a result of this. It is emphasized that, with a spark-over vacuum, the significance or value of the gap, but not that of the discharge potential, depends on the density of the charges of the double electrical layer.

In regard to the above formula, it has been shown that, choosing a definite value for density of electric charge, and using values of the potential $V$ directly observable in the discharge tube under different gas pressures (including those in which discharge proceeds without participation of the gas itself), one can predict—in determining the work of removing the film ($A$) and in accord with experiment—how this value ought to change with changes in pressure and nature of ambient gas. Thus, by selecting the right value for density of charge of the double layer, agreement with experimental results can be obtained both under ordinary atmospheric conditions and under those of widely varying gas pressures. It is therefore claimed that the new theory, as regards agreement with experiment, has decisive advantages over the conventional theory that takes little account of gas pressures.

The new theory includes also an explanation of the experimentally found values of work done—up to $10^6$ ergs/cm.$^2$ or even more. In such cases, charge densities are obtained corresponding to a potential jump of not more than one volt; and this is only exceeded during the tear-away without discharge, when the voltage may be up to 10 kV. or more at discharge, according to charge density and pressure of ambient gas. Other evidence of the validity of the new electric theory is claimed by Deryagin to have been found in the observation and measurement of speed and energy of electrons emitted during tear-away of films in vacuum from metallic and non-metallic backing. He describes a method of observation, using a photographic film, an absorbent screen of thin foil or mica sheet for maximum speeds, and a magnetic field for determining deflexion. It was found, in agreement with theory, that intensity and energy of emission increased with speed of tear-away, and charges of 10 or more kV. are mentioned. They are of such magnitude that the work expenditure may be attributed mainly to overcoming these electrical forces.

Deryagin acknowledges, however, that this method of measuring electron speeds cannot be said to have a high degree of accuracy. Thus, without necessarily contradicting these measurements, it may be suggested that some part of the work, say 30–40 per cent, may be devoted to something else, such as deformation of the film during removal, with possible evolution of heat. But Deryagin is satisfied that these objections have little or no basic significance, and he produces lengthy arguments in support. He is quite certain that, compared with the electrical component, the molecular component is practically negligible.

It is easy to explain the effect of adsorption of dipole molecules on adhesion, as these form an oriented dipole molecular layer and may considerably modify the value of the potential jump. Some cases of such modification have been studied by A. N. Frumkin. Various considerations lead to the view that the effect is indirect, and may either increase or reduce adhesive power—as appears to be confirmed by experiment. Chemical interaction sometimes doubtless plays an important part, and the example of rubber-to-metal through vulcanization is again cited. But this by no means belittles or invalidates the new electrical theory. As already stated, the work expended on tear-off of film is usually much greater than that needed to break the chemical bonds. Mechanical fracture of the diamond illustrates the absurdity of opposing chemical to mechanical and electrical factors. Reference is made to some Russian work on the electron theory of chemical affinity and of atom adsorption in crystal lattices. Similar reasoning may be applied in passing from surface adsorption to contact of a film with solid bodies, where the film contains mainly a polymer in solution—as is mostly the case with coating or adhesive films. The active atoms or groups in the film may enter into electronochemical union, accompanied by transfer of electrons from one phase to the other, obviously leading to formation of the double electric layer.

A possible objection to the new theory is to be found in the query: Why, in adhesive breakdown (delamification), is the double electric layer split up, though having in many cases the nature of a strong chemical bond, while there is little or no cohesive break along a line, probably of less or even of least resistance? Deryagin's reply is not very clear. He thinks that the principle or rule under which breakdown should occur along a line of least resistance is ambiguous and generally futile until a satisfactory measure of resistance is agreed. This line may vary, for example, with changes in speed of load application. If we consider splitting along a surface, in stages, and the measure of resistance is taken to be the specific work expended in tear-off, the principle of least resistance completely loses validity. This is discussed somewhat vaguely by Deryagin, and at length, including non-adhesive examples. In any event, it appears necessary to develop the theory somewhat further to permit combination of charge density in the double layer with the nature of functional groups in the adhesive, the presence there of active atoms and radicals, and the interaction between these structural elements of the adhesive and the surfaces to be joined.

Another approach to the problem of the origin of the electrical double layer, though possibly more limited, is to be found in studying the contact of a polymer film with metal. This is considered in connexion with electron transfer with the production of electron gas in the metal. In a vacuum such a transfer is only possible at high temperatures, such as those of thermo-emission or photo-effect. The formation and diffusion of the electron cloud and its results are also considered.

Referring to work in the United States by Skinner and colleagues[5], Deryagin considers that their theory of formation of an electrical double layer contains quite a few errors "and is probably only of qualitative interest"; Skinner *et. al* do not cite any of the Soviet work on this electrical theory of adhesion, and he claims that they have ignored the fundamental difference between simultaneous and gradual disturbance or fracture of contact over the whole area. There is no doubt, he continues, that the research already begun on the nature of film adhesion merits wider development, especially if this includes the really practical evaluation of adhesives in different fields of Soviet economy. It is very important to establish closer contact with workers in manufacturing industry directly engaged on new adhesive formulations and uses, and also those particularly interested in building up a sound scientific theory of adhesion.

Of special interest here is the so-called auto-conglomeration or self-adhesion (using terminology suggested by I. I. Zhukov) as observed in bringing into contact two identical strips of polymer, such as rubber. Experiment shows that the work of separating such double-folded strips increases not only with the speed of tear-off, but also with the duration of previous contact and amount of pressure. Such auto-adhesion, of course, is greatly affected by temperature conditions. All these various relations, including that between the structure of the polymer chains and their length, have been studied by different workers—for example, Voyutskii, Krotova, Deryagin and others—who have suggested that the phenomena of self-adhesion to a large extent are determined by intra-molecular thermal movement, forming the basis of polymer elasticity and leading, with contact of two polymer surfaces, to mutual interweaving and diffusion of their chains.

Thus, the surface of separation initially retained on bringing into contact two homogeneous polymers gradually disappears, and instead of two layers of polymer only one exists. Separation or tear now proceeds elsewhere, and the work involved is typical of the cohesion of the material. It is difficult to separate the macroscopic process, of gradual increase of true surface of contact of two materials, from the molecular mechanism of diffusion and interlocking of polymer chains. The initially true area of molecular contact will be considerably less than the apparently nominal. But gradually, owing to flow and relaxation of the polymer, the true area of contact will increase—with a tendency to approach the nominal. Since relaxation and plastic flow in polymers in turn are connected with deformation of macromolecular chains, it is difficult strictly to separate the two mechanisms—molecular coalescence and plastic flow in the contact zones. Further experimental research is necessary, including study of other fields of adhesion phenomena which, in the course of this review, cannot be considered here.

# JOINT ESTABLISHMENT FOR NUCLEAR ENERGY RESEARCH

## REPORT FOR 1953–54

THE third annual report of the Joint Establishment for Nuclear Energy Research, which has recently been issued*, contains details of the activities of the Establishment during the year ending June 30, 1954. The Establishment, which is located at Kjeller in Norway, is operated jointly by The Netherlands and Norway and is directed by Mr. Gunnar Randers. The experimental equipment includes a 300-kW. heavy-water-moderated, natural-uranium reactor, Joint Establishment Experimental Pile (JEEP), which has been in continuous operation during the year, though four of the uranium rods were found to be defective and had to be replaced. An additional rod, bringing the total up to sixty-five, was required in order to compensate for the heavier load of isotopes. New equipment installed during the year included a pneumatic arrangement for removing isotopes quickly from the reactor and a mechanical master-slave manipulator for remote handling of radioactive material.

---

* Joint Establishment for Nuclear Energy Research. Third Annual Report, 1953–54. Pp. iii+28. (Kjeller, near Lillestrøm: Joint Establishment for Nuclear Energy Research, 1955.)

The design of an experimental power reactor in which heavy water and natural uranium are to be used in a pressurized system has continued. The general planning has now reached an advanced stage, and recent work has been concentrated on the design of the natural-uranium fuel elements. The reactor is to be contained within a cylindrical pressurized stainless-steel tank, and the cooling circuit for the fuel elements, which is separated from the moderator, will provide hot heavy-water which will be used for steam production in a boiler connected to a conventional type of turbogenerator.

In November 1953 an extension to the building housing the pile was completed, and the physics, isotope and electronics laboratories and the offices for the Operations and Engineering Department are now housed together in this building. In June 1954 work was started on a new laboratory and workshop building to house the metallurgy and engineering groups and the Reactor Physics Department.

Work in the Chemistry Department has been divided between service tasks for other departments and the study on a laboratory scale of the chemistry of uranium and plutonium, particularly in order to design a pilot plant capable of dissolving up to ten tons of burned uranium rods a year, including the separation of plutonium and the reprocessing of the uranium metal. A 'hot' uranium slug was dissolved in concentrated nitric acid in an all-glass apparatus, the experiment being carried out by remote control behind a 40-cm. thick water wall. The solution obtained contained about 10 mgm. of plutonium. Arrangements have been made for the production of uranium metal by the reduction of uranium tetrafluoride with calcium. The uranium tetrafluoride was produced in accordance with the French method, that is, by reduction and fluorination of uranium tetraoxide, and the report states that uranium of a fair degree of purity has been obtained. Although the metallurgical laboratory is still under construction, some of the metallographic equipment has arrived, and studies of the de-gassing of uranium at elevated temperatures have been undertaken. The stabilization and canning of the uranium and the diffusion of uranium and aluminium at 200° C. and higher temperatures are other problems which have engaged the attention of the metallurgical group.

The production of isotopes has greatly increased, and the number of radioisotope shipments, namely, 335, is more than double that for 1952–53; 65 per cent of these shipments were for export. The different types of isotopes produced and the number of irradiations made in the several departments of the Establishment, together with the number of shipments, their destinations and main fields of application, are listed in the annual report. Stocks of radiocobalt and of radioiridium with fairly high specific activity suitable for industrial radiography have been developed, and many special isotope preparations of medical interest are, or will shortly become, available. No increase in the number of isotopes imported for distribution in Norway is reported. Eighty-four shipments were received from Great Britain, one from the United States and one from Canada. Three examples to illustrate the different technical applications of radioactive isotopes carried out by the Isotope Department during the year are described in some detail in the report. They are concerned with the transport of materials in rotary cement kilns, the loss of catalyst material in the industrial production of nitric acid, and the wear of ball bearings.

The sections of the report devoted to the activities of the Neutron Physics and Reactor Physics Departments are particularly interesting. The fission cross-section of uranium-235, the crystal structure of copper hydride and the magnetic structure of magnetite have been studied by the Neutron Physics Department. The principle of operation of the simple mechanical monochromator for neutrons used at the Establishment, the results of measurements of the rate of fission cross-section of uranium-235 and $(n,\alpha)$ cross-section of boron as a function of neutron energy, and the neutron diffractometer used for crystal structure analysis are some of the topics discussed in the report. The critical factors of various reactor designs were studied by the Reactor Physics Group; other problems considered were shielding properties of concrete, the effect of prompt and delayed $\gamma$-emission on the reactivity of the Pile and the rate of plutonium production in heavy-water reactors.

The report concludes with a list of the Establishment's reports and publications issued during the year, details of the staff of the various departments, and an abstract of the financial accounts for the period under review.

# THE PHYSICAL SOCIETY

## REPORT FOR 1954

THE report of the Council of the Physical Society for the year ending December 31, 1954, together with the report of the honorary treasurer and the annual accounts and balance sheet, were presented to the annual meeting of the Society held at the Royal Institution, London, on May 11, and adopted. Immediately following the annual meeting, Prof. H. S. W. Massey delivered his presidential address, entitled "Progress and Problems of Physics To-day", in which he described a selection of remarkable achievements in recent research in physics which illustrate the very advanced state of technique to-day, and then dealt with some of the problems, for example, the growing shortage of science teachers in schools and the tendency to extreme specialization, which the great expansion of research in physics has raised. The text of his address will be published in the separate issue of the *Proceedings* of the Society to be called the "Proceedings of the Physical Society Yearbook". The "Yearbook" will also contain the texts of the 1955 Guthrie Lecture and the Thomas Young Oration.

The report states that during the year the student membership of the Society decreased by approximately a quarter to 279, and the total membership fell to 2,046 with a net decrease of eighty-four. There was a small balance of income over expenditure; but the financial position at the end of 1954 was markedly less favourable than at the end of 1953, the deterioration being attributed, in particular, to a decrease in the income from the annual exhibition of scientific instruments and to the absence, in 1954, of a grant-in-aid in respect of the Society's publications. It is true that the cost of the Society's publications, including its commitment in respect of *Science Abstracts*, was almost balanced by the income from sales; but the total cost of the Society's activities continues to rise and gives cause for considerable anxiety.

Five science meetings were held in London during 1954, including the summer meeting on July 7, 9 and 12, which was held in the Royal Institution in connexion with the General Assembly of the International Union of Pure and Applied Physics. Meetings outside London were held in University College, Dublin, during March 30–April 1, and in the University of Birmingham during December 13–14. In addition, a conference on the physics of the ionosphere was held in the Cavendish Laboratory, Cambridge, during September 6–9. The thirty-eighth Guthrie Lecture[1] was delivered by Sir Geoffrey Taylor, who spoke on diffusion and mass transport in tubes, and the seventh Rutherford Lecture by Prof. P. M. S. Blackett. Prof. A. Kastler, of the University of Paris, was the recipient of the ninth Holweck Medal of the Société Française de Physique and the Holweck Prize of the Physical Society; the presentation took place at the Royal Astronomical Society, Burlington House, on May 13, 1954, when Prof. Kastler delivered the Holweck discourse[2] entitled "Les méthodes optiques d'orientation atomique et leurs applications". The thirty-first Duddell Medal was presented to Prof. A. C. B. Lovell, who gave an address on the development and use of large radio telescopes, and the tenth Charles Vernon Boys Prize to Dr. J. S. Courtney-Pratt, who spoke on some new methods of fast photography.

At the request of a number of members, the Society reprinted the first five Rutherford Memorial Lectures, and the pamphlet, entitled "Rutherford, by Those who Knew Him", has been well received. Two special reports, "Defects in Crystalline Solids", representing the proceedings of a conference on this subject held in the University of Bristol during the meeting of the International Union of Pure and Applied Physics, and "The Physics of the Ionosphere", the proceedings of the Cambridge conference on this subject, have recently been issued. Vol. 17 of "Reports on Progress in Physics", containing eight reports, was published during 1954. A new departure was the issue, in addition to the bound volume, of each report as a separate booklet, with paper covers, to be purchased in any required quantity.

The thirty-eighth annual exhibition of scientific instruments and apparatus held at the Imperial College of Science and Technology, London, during April 8–13, 1954, had an attendance of approximately eighteen thousand and was again a great success. The four subject-groups of the Society—the Colour, Optical, Low Temperature, and Acoustics Groups—were all active during the year, and brief details of their membership and meetings are listed in the annual report. The summer meeting of the Low Temperature Group consisted of a visit, led by Dr. K. Mendelssohn and Dr. F. Din, to West Germany; on May 7 the party inspected the oxygen plant of the Messer Company at Hagen-Haspe, and during May 8–9, at Göttingen, a joint session was held with members of the German Physical Society at which scientific papers were read. A list of the numerous bodies and committees on which the Society is represented is also included in the report.

At the annual general meeting the officers and council of the Society for 1955–56 were elected as follows: *President*, Prof. H. S. W. Massey; *Vice-Presidents*, Dr. R. C. Evans, Dr. A. B. Wood, Prof. S. Devons and Prof. F. Llewellyn Jones; *Honorary Secretaries*, Dr. C. G. Wynne and Dr. H. H. Hopkins; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Treasurer*, Mr. A. J. Philpot; *Honorary Librarian*, Dr. R. W. B. Pearse; *New Ordinary Members of Council*, Prof. W. E. Burcham, Prof. H. Jones and Mr. D. A. Wright.

# NITROGEN NUTRITION, RESPIRATION AND AGEING IN *LEMNA* FRONDS

IN a constant and favourable environment, each frond of *Lemna minor* has a finite length of life and a rate of ageing characteristic of the clone in its particular environment. Ageing, and the progressive diminution in frond-size which accompanies it, are not attributable to the production of daughter fronds, nor to a lack of auxin or adenine. Further, it has been found in surgical experiments that daughter frond area is determined by some substance in the mother frond (not auxin or adenine) which diminishes or is inactivated as the mother frond ages. E. Wangermann and H. J. Lacey (*New Phytol.*, **54**, 2, 182; 1955), in further investigations, have examined the relationship between nitrate nutrition, rate of respiration, and rate of ageing in *Lemna* with the following results.

Maximum length of life and minimum rate of ageing occurred at the lowest nitrogen-levels (less than 0·1 mgm./l.); minimum length of life and maximum rate of ageing occurred at intermediate nitrogen levels (about 0·25 mgm./l.). When rates of respiration of fronds at high and low nitrogen-levels were measured by the Warburg manometric technique, it was found that the rate of respiration of the low-nitrogen fronds (on an area or dry-weight basis) was below that of the high-nitrogen fronds throughout the whole of their life. There was no trend towards reduction in rate of respiration between maturity and death. The length of life was recorded of fronds the respiration of which was periodically inhibited by keeping them in an atmosphere of nitrogen during the dark period. Fronds thus treated lived considerably longer than those the respiration of which was not interfered with. From these results and those of previous experiments, it is tentatively suggested that a causal relationship may exist between rate of respiration and rate of ageing, slow respiration resulting in long life and *vice versa*.

# A NEW FAMILY OF EARLY PRIMATES

THE known primates and primate-like animals from the Palæocene and Eocene of North America and Europe are extraordinarily diverse. All are distinctly pre-anthropoid in structural grade and are considered in a general sense to be Prosimii or, in some cases, primate-like Insectivora. There has been a tendency to compare them either with the tarsiers or lemurs and to place them in the categories Tarsiiformes and Lemuriformes. Most of the supposed early Tarsiiformes have been classified as Anaptomorphidae, and most of the supposed early Lemuriformes have been called Adapidae. A few other families, notably the Plesiadapidae, were also early recognized, although not well defined until more recently.

Over the years it has become evident that the early Cenozoic complex of primates and primate-like insectivores is far more complex than the usual classifications have recognized. It is also increasingly clear that the placing of many or, perhaps, any of them in the essentially Recent categories Tarsiiformes and Lemuriformes is arbitrary and is not a clear expression of their real affinities. A more recent tendency has been to pick out from the mass smaller groups of genera and species which are related among themselves, whatever may be their relationships to their contemporaries or to Recent prosimians, with which most of them seem to have no special relationships.

*Phenacolemur*, a member of this early complex known since 1915 when it was named by Matthew, is a highly distinctive, primate-like animal. It was at first confused with the distinctly different Plesiadapidae and Apatemyidae and recently has been considered simply as a primate, or perhaps insectivore, *incertae sedis*. Knowledge of the genus has increased, and there are now numerous specimens in collections from the late Palæocene and early Eocene Mountain region. Among recent discoveries is a specimen with associated upper and lower jaws and a skull. George Gaylord Simpson now gives a much fuller account of the genus than any in the scattered literature and considers its affinities on a far better basis (*Bull. Amer. Mus. Nat. Hist.*, 105; 1955). A fairly well-defined group, designated as the Phenacolermuridae, emerges as a further contribution to the clarification of the heterogeneous mass of early Cenozoic primate-like mammals.

# STRUCTURE OF POLY-L-PROLINE

By PAULINE M. COWAN and STEWART McGAVIN
Wheatstone Physics Laboratory, King's College, London, W.C.2

THE configuration of the peptide linkage which involves proline nitrogen is at present unknown. A knowledge of its configuration has an important bearing on the determination of the structure of proteins containing proline, especially that of collagen. Collagen not only contains a high proportion of proline and hydroxyproline, but also recent evidence[1] (and unpublished work by Kroner, Tabroff and McGarr) suggests that the sequence (pro, hypro) occurs as a significant fraction of the total.

Poly-L-proline has recently been synthesized by Berger, Kurtz and Katchalski[2]. They have very kindly supplied us with a sample having an average degree of polymerization of $n = 20$ which had been obtained by polymerization in dioxane. We have examined this material by X-ray diffraction.

The untreated material gave an X-ray powder pattern, all reflexions of which could be indexed on a hexagonal lattice with $a = 6 \cdot 62$ A. and $c = 9 \cdot 36$ A. No reflexions were observed at positions corresponding to indices 0001, 0002, 0004, 0005; but there were no other systematic absences. This indicates a three-fold screw axis parallel to $c$.

These deductions were confirmed by photographs of oriented films obtained from solution in *m*-cresol. The X-ray diffraction patterns first obtained from these films indicated a more complex lattice in which solvent was clearly incorporated. In the course of time, solvent was lost and a fibre diagram was obtained in which the reflexions had spacings the same as those of the original sample (Fig. 1). In the oriented films the $c$-axis was parallel to the direction of shear. Poorly oriented fibres were also obtained in which the $c$-axis was perpendicular to the fibre axis. Photographs of the original powder dispersed from alcohol were taken by Mr. R. E. Burge of this laboratory by means of electron diffraction, and show reflexions on a hexagonal net giving $a = 6 \cdot 57$ A.

The density of the original material was found by flotation in benzene/carbon tetrachloride mixtures to be $1 \cdot 32$ gm.cm.$^{-3}$. This is in reasonable agreement with the value, $1 \cdot 36$ gm.cm.$^{-3}$, calculated for three proline residues in the unit cell. The structure must therefore consist of polypeptide chains situated at trigonal positions, each having three equivalent residues related by an exact threefold screw axis, the 'residue repeat' along the $c$-axis being $3 \cdot 12$ A. These conclusions, and the lack of symmetry in the amide group, limit the space group either to $P3_1$ or $P3_2$.

In crystal structures of simple peptides, the amide group normally has a planar *trans* configuration[3]. It seemed reasonable to suppose that this configuration would also occur in poly-L-proline; but, in view of the unique character of the residue, models were also constructed with planar *cis* groups and

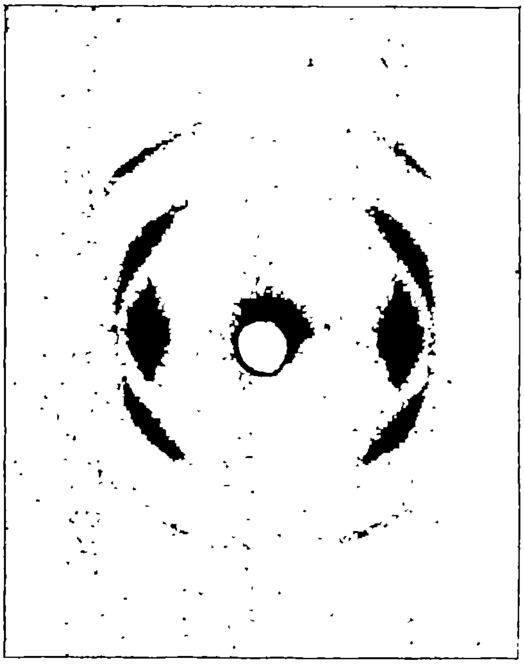

Fig. 1. X-ray diffraction photograph of poly-L-proline sheet oriented from *m*-cresol, slightly tilted, X-ray beam parallel to sheet

with pyramidal nitrogen. The proline ring[4] is puckered, with the γ-carbon atom of the 'side chain' about 0·5 A. from the plane of the other atoms in the ring. Such a ring can readily be attached to an amide group without great distortion of valency angles. In preliminary model building, the ring may be assumed to be planar.

In *cis* amide groups the distance between α-carbon atoms is expected[5] to be about 2·83 A. Considerable distortion of bond angles is necessary for the construction of a chain with repeat of 3·12 A., if composed only of *cis* residues, and such a structure is considered improbable. A model of the required dimensions can be built using pyramidal nitrogen. It seems likely, however, that the proline ring would tend to stabilize a planar form of the amide group. The reported value[3] of the C=O stretching frequency of 1,640 cm.$^{-1}$ tends to confirm this view (the low value being associated with considerable resonance in the amide group). Attention was turned chiefly to the construction of models consisting of the planar *trans* form.

Using, in the first instance, a completely planar residue, with dimensions close to the normal values[5], it was shown that a three-fold helix with repeat 3·12 A. could be constructed if some distortion is allowed at the α-carbon atom. The actual angles depend on the tilt of the plane about the line joining α-carbon atoms. Two models were considered: (1) with $C_2$—α$C_1$—$N_1$ and $C_2$—α$C_1$—β$C_1$ respectively 116° and 103° (both as near tetrahedral as possible); (2) with $C_2$—α$C_1$—$N_1$ and $C_2$—α$C_1$—β$C_1$ 109° and 97° respectively. Both forms are strained. In addition, (1) has two short contacts, $O_2$ to $N_1$, 2·90 A. and $O_2$ to β$C_1$, 2·86 A. In (2) the strain can be relieved by removing β$C_1$ from the plane of the ring by 0·4 A., when $C_2$—β$C_1$ becomes 111°. This arrangement is illustrated in Fig. 2, and co-ordinates for the atoms of a single residue are given in Table 1. In this model, all contacts between non-bonded atoms are normal, with the exception of $O_2$ to $N_1$, 2·72 A. No hydrogen bonding is possible, but substitution on the nitrogen might be expected to increase the polarity of the amide group, since the increased polarizability of the substituted nitrogen facilitates further transfer of negative charge to the oxygen. Attraction between $O_2^{\delta-}$ and $N_1^{\delta+}$ might be expected to favour a *cis* arrangement of the $C_2$—$O_2$ and α$C_1$—$N_1$ bonds, but this is prevented by steric hindrance between $O_2^{\delta-}$ and $O_1^{\delta-}$. The position adopted in the model corresponds to a rotation of nearly 30° from this orientation (that is, close to the alternative configuration suggested by Pauling and Corey, but considered by them to be less favourable, ref. 5, p. 731). It is very similar to that of the carbonyl C—O with respect to the C—$\overset{+}{N}$ ($H_2$) bond in β-glycyl glycine[6] and unlike that preferred by the carboxyl C—O, which is very nearly coplanar with the adjacent C—N in this and almost all other peptides and amino-acids.

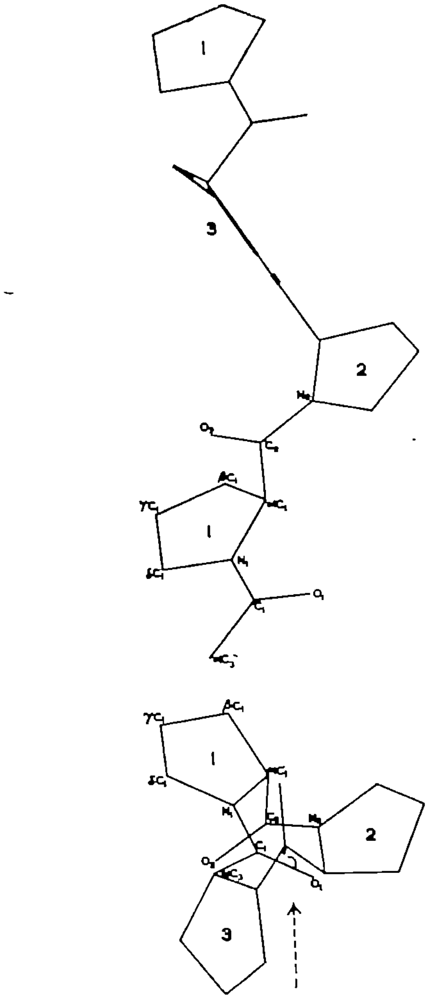

Fig. 2 Single chain of proposed model for poly-L-proline, seen in projection, below, along the threefold screw-axis, and, above, perpendicular to this axis and along the direction indicated by the arrow

Table 1. POLAR CO-ORDINATES FOR A SINGLE RESIDUE OF THE PROPOSED MODEL FOR POLY-L-PROLINE

| Atom | $r$ | $\varphi$ | $z$ |
|---|---|---|---|
| α$C_2$ | 1·30 A. | 0° 00′ | 0·00 A. |
| $C_2$ | 0·32 | − 12° 30′ | 1·14 |
| $O_1$ | 1·14 | − 109° 30′ | 1·28 |
| $N_1$ | 1·01 | 76° 00′ | 1·95 |
| α$C_1$ | 1·30 | 120° 00′ | 3·12 |
| β$C_1$ | 2·68 | 103° 30′ | 3·44 |
| γ$C_1$ | 3·17 | 77° 00′ | 2·86 |
| δ$C_1$ | 2·44 | 63° 00′ | 1·75 |

It is of interest to note that the helix described is left-handed if the absolute configuration of the α-carbon atom is assumed[7]. A right-handed helix of the required dimensions cannot be built with L-residues. The space group is therefore $P3_2$.

The positions of the three-fold axes of the chains are fixed by symmetry. The actual positions of the atoms with respect to the unit cell axes are not fixed, and these will be determined largely by van der Waals interactions between atoms in adjacent chains. For the above model two packing positions appear to be possible, one of which gives better agreement between observed and calculated intensities than the other. This arrangement, however, includes regions of rather low density. A somewhat more even distribution may be achieved by changes in the exact configuration. In the absence of hydrogen bonding, some rotation may be allowed about the C—N bond, as in N,N′-diglycyl cystine[8]. Both γ- and β-carbon atoms may be in a plane other than that of the amide nitrogen. Refinements along these lines are proceeding, together with an attempt to obtain better data with which to test the model. Details will be published elsewhere.

A perpendicular dichroism for the infra-red C=O stretching frequency has been observed in oriented films by Mr. G. R. Wilkinson of this laboratory, to whom we are indebted, and this is in agreement with our model.

From steric considerations the helical configuration is likely to be rather closely maintained in solution, which may account for the high specific lævo-rotation[2]. Again, in collagen, the polypeptide chains may have a similar, although less tightly coiled, configuration. This will be discussed elsewhere.

We thank Prof. E. Katchalski and his co-workers of the Weizmann Institute, Rehovoth, Israel, for making several samples of the polymer available to us and for their comments on our work. We are also grateful to Prof. J. T. Randall for his continued advice and encouragement throughout the course of this work. We should like to acknowledge the helpful discussions we have had with our colleagues of this laboratory, and with Mrs. D. M. Hodgkin of the Chemical Crystallography Laboratory, Oxford. We are both indebted to the Nuffield Foundation for the award of research fellowships, during the tenure of which this work has been carried out. [May 17

# CHANGES IN ANIMAL TISSUE AFTER HYDROCORTISONE ADMINISTRATION

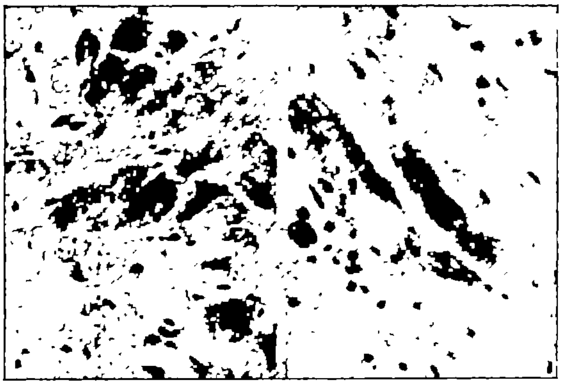
## Production of Dystrophic Calcification of Cardiac Muscle in Mice by Hydrocortisone

In the course of studies on the growth of a transplantable mammary carcinoma in mice as influenced by the administration of adrenal and pituitary hormones, we made the unexpected observation that dystrophic calcification is produced in the myocardium of animals treated with hydrocortisone. So far as we are aware, this type of lesion has not previously been noted as a result of hydrocortisone therapy.

Fifty-four virgin female mice of the $C_3H$ strain, 2–3 months old, were inoculated by trochar with fragments of a transplantable mammary adenocarcinoma in the subcutaneous tissue of the back. Seven days later the animals were apportioned into two groups. One group (twenty-five mice) served as a control, and the remaining animals were injected with hydrocortisone acetate (Merck) according to the following regimen of daily doses: 0·2 mgm. for fourteen days, followed by 1·0 mgm. for twenty-one days, with a final dose of 0·5 mgm. until the end of the experiment. Both groups received a daily dose of 1·0 mgm. of terramycin in addition to the hormone; all injections were administered subcutaneously. The average survival-times of the experimental and control groups were 40 (28–78) and 52 (24–77) days respectively. At the end of the experiment, the average weight of the tumours in the group injected with hydrocortisone was only 0·5 gm., while that of the controls was 13·3 gm. at death. These data confirm the previous observations[1] that hydrocortisone inhibits the growth of transplantable tumours, in addition to shortening the survival-time of the tumour-bearing animals.

Calcific deposits were grossly visible in the heart tissue of those mice which survived treatment with the adrenal hormone for thirty days. The extent of deposition was roughly proportional to the length of survival and hence to the duration of the injection period. Microscopically the hearts showed extensive calcification and degeneration of the muscle fibres (Fig. 1). The nuclei manifested occasional variability with respect to size and shape, some being small and pyknotic. There were granular, basophilic deposits of variable size spread throughout the myocardium of the right and left ventricle and the interventricular septum. The smallest deposits were located within muscle fibres, and were found to stain typically with the alizarin red stain for calcium. In contrast, no such lesions were seen in the myocardium of any animal in the control group.

Additional studies in tumour-bearing $C_3H$ mice have shown that similar myocardial degeneration associated with the deposition of calcium can be produced by high doses of adrenocorticotrophic hormone. Concomitant injections of growth hormone, with either hydrocortisone or adrenocorticotrophic hormone, seemed to potentiate these changes, whereas prolactin prevented their appearance. Non-tumour-bearing female $C_3H$ mice treated for ten days with hydrocortisone and autopsied forty-five days later also manifested similar degenerative changes. In



(*A*) (*B*)

Fig. 1. (*A*), cross-section of cardiac muscle of a tumour-bearing mouse treated with hydrocortisone acetate for a period of 35 days. The various stages of calcification of the fibres should be noted: the earliest stages are represented by granular basophilic material in the fibres and the later stages by more extensive areas of calcium deposition. (Hæmatoxylin and eosin, × 280.) (*B*), longitudinal section of cardiac muscle of a tumour-bearing mouse treated with hydrocortisone acetate for a period of 35 days. Calcification of the muscle fibres and the slight mononuclear cell response should be noted. (Hæmatoxylin and eosin, × 280) another study[2], where analogous observations were made in normal animals treated with hydrocortisone, biochemical investigation of the heart tissue confirmed the histological observation that deposition of calcium is associated with these lesions.

These incidental findings obtained with a potent hormonal agent emphasize that, when one has recourse to a hormone for one specific therapeutic effect, it is essential to bear in mind the tremendously far-reaching effects that may be exercised by that hormone on all tissues of the body.

This investigation was supported in part by grants from the Cancer Board of the University of California, and the Albert and Mary Lasker Foundation.

## Deposition induced by Hydrocortisone of Calcium in the Heart Tissue of Female $C_3H$ Mice

It is reported in the previous communication that chronic administration of hydrocortisone acetate to tumour-bearing $C_3H$ mice in high dosages produces degeneration of the cardiac muscle fibres. Histological examination of the heart tissue revealed deposition of a mineral material which stains positively with an alizarin dye, suggesting the presence of calcium. These observations have now been confirmed in acute experiments with normal female mice of the $C_3H$, Heston *A* and *B*-albino-*C* strains. Progressively higher values for the calcium content of the heart tissue, as determined by the spectrophotometric method, were noted in hydrocortisone-treated animals as the hormonal dosages were increased, paralleling the degree of mineral deposition observed grossly. These findings invite interesting speculation with regard to the similarity between what is noted here and the pathological changes seen in certain clinical conditions[1,2], although extreme caution must be employed in translating data from one species to another.

Virgin female mice (fifty days of age) of the $C_3H$ strain were given daily subcutaneous injections of either saline or a saline suspension of hydrocortisone acetate (Merck), in a daily dose of 0·25–2·5 mgm. As a prophylactic measure, all animals were also injected intraperitoneally on the first two days with 1 mgm. of terramycin in 1 ml. of a 5 per cent glucose solution; despite this precaution, several of the treated mice succumbed to infection. Only those surviving the entire period of injection have been included in the final analysis.

On the day following the tenth injection, the animals were anæsthetized with nembutal; the heart, adrenals and thymus were removed and weighed. For the calcium determinations, the heart tissue from four or five animals was pooled in a porcelain crucible and ashed in a muffle furnace at 900° F. The ash was taken up in concentrated hydrochloric acid and the calcium was precipitated as the oxalate[3] at approximately $pH$ 4. Following centrifugation, the precipitate was thoroughly washed with 2 per cent ammonium hydroxide, dissolved in 1 *N* hydrochloric acid and made up to a 5 ml. volume with distilled water. The calcium content was then estimated in a flame spectrophotometer at 554 mμ with appropriate standard solutions[4].

Results are summarized in Table 1. As was to be expected, hydrocortisone caused thymic involution and adrenal atrophy; in addition, the hormone produced hypertrophy of the heart tissue. The spectrophotometric analysis of the myocardium afforded both identification of the mineral deposition as a calcium salt, and a means for quantitative estimation of the calcium content, which was shown to be a function of the hormonal dosage. While only small increases were obtained with 0·25 mgm. of the hormone, a ten-fold increase was evident at a dose-level of 1·0 mgm. The microgram quantities listed in the table for calcium should not be thought of in absolute terms, since some variation was found from week to week between appropriate groups given a standard amount of hydrocortisone for the 10-day period. Nevertheless, the comparative increases of calcium observable in the groups receiving progressively higher hormonal dosages were remarkably constant.

Table 1. THE EFFECT OF HYDROCORTISONE ACETATE ON ORGAN WEIGHTS AND CALCIUM DEPOSITION IN $C_3H$ MICE

| Daily dosage (mgm.) | No of mice | Body weight at autopsy (gm.) | Adrenal weight (mgm.) | Thymus weight (mgm.) | Heart | |
|---|---|---|---|---|---|---|
| | | | | | Weight (mgm.) | Calcium content (μgm / 100 mgm.) |
| 0 | 10 | 19·5 | 4·0 ± 0·1* | 41 ± 2·4 | 92 ± 3·6 | 2·2 |
| 0·25 | 7 | 17·0 | 3·0 ± 0·03 | nil | 124 ± 9·1 | 6·4 |
| 0·50 | 10 | 18·5 | 2·9 ± 0·06 | nil | 124 ± 3·9 | 17·2 |
| 1·0 | 5 | 18·0 | 3·1 ± 0·1 | nil | | 25·3 |
| 2·5 | 5 | 17·0 | 2·8 ± 0·4 | nil | | 27·9 |

* Mean ± S.E.

No conclusion can be drawn from the present results with regard to the amount of circulating steroid necessary to induce the observed pathological changes. When the hormone is administered subcutaneously as a saline suspension, considerable quantities of unabsorbed material accumulate beneath the skin. Moreover, doubling the dosage offers no assurance that the total absorption is increased proportionately.

Irrespective of these recognized variables in absorption, these results indicate clearly that the hydrocortisone administered is responsible for the relatively constant occurrence of calcific depositions in the right ventricle of the heart and for their incidental appearance in the liver and other viscera. The mechanism of its action and the influence of other endocrine factors remain to be investigated.

We wish to thank the Albert and Mary Lasker Foundation for research grants which have aided greatly in this investigation.

## Palæomagnetism of Sediments from the Colorado Plateau

On the Colorado Plateau of Arizona and Utah there are exposed, as a result of erosion, sedimentary strata substantially undisturbed since deposition, representing almost every period of geological time. In the Grand Canyon of the Colorado River, for example, there are sediments ranging in age from the late Pre-Cambrian or Algonkian to the Permian, and in Zion Canyon and the Painted Desert Mesozoic sediments are found. Thus this part of the southwestern United States is ideal for palæomagnetic work, and I had long wished to make a collection of rocks there for this purpose.

A further advantage of this group of rocks is that throughout the geological column fine-grained red sandstones frequently occur. Experience in palæomagnetic measurements in Great Britain[1] has demonstrated that these sediments are particularly suitable for this work. In any one formation the directions of magnetization of different specimens are reasonably closely grouped together; presumably because quiet conditions during deposition enabled the magnetized iron oxide mineral grains to set with their magnetizations parallel to the geomagnetic field at that time. The magnetizations of such red sandstones can often be shown by certain field-evidence to have remained unchanged in direction, relative to the rock, since deposition; presumably because the high coercive force of the hæmatite, usually the chief ferromagnetic mineral, gives the rock a high magnetic stability.

Last summer, thanks to grants from the Geological Society of America and the Museum of Northern Arizona, I was able to carry out the necessary field-work, the remanent magnetization of the samples obtained being measured early this year with the Cambridge astatic magnetometer. Measurements of the palæomagnetic directions in Tertiary times[2] (1–60 million years ago) had shown that the mean geomagnetic field in this period is very closely that of a geocentric axial dipole along the earth's present axis of rotation. Similar measurements in Great Britain[3] on pre-Tertiary sediments and igneous rocks had shown that the mean palæomagnetic direction changes slowly through geological time, but not appreciably in any one period (about fifty million years on the average). These results have been interpreted[3] in terms of a slow migration of the axis of rotation through the earth carrying with it the mean axis of the geomagnetic field. This is quite a different phenomenon from that of reversals of the magnetization of rocks, which are geologically rapid phenomena and are inferred to be due to reversals in polarity of the geomagnetic field, which regains its axial character when the reversal is completed. The measurements of the Arizona strata provide the opportunity for a test of the polar-wandering hypothesis, and the results are here summarized.

Table 1 compares the positions of the north pole from United States formations of five different periods with the positions calculated from the European formations of the same or similar geological age. These positions are normally computed from the mean direction of magnetization of a number of samples well separated stratigraphically. But in one formation (the Springdale sandstone) the palæomagnetic direction taken is not that of the mean but one which allows approximately for the appreciable magnetic instability of these sandstones, which biases their mean direction towards that of the present geomagnetic field. In the other cases a curve may be described around the pole position which, to a probability of 95 per cent, will contain the true position of the pole for that period. The two semi-axes of this curve are listed in brackets below the respective pole positions in Table 1.

The motion of the pole as deduced from the measurements of British strata consists of a gradual movement from near Hawaii in late Pre-Cambrian times towards the Pacific coast of Asia in Palæozoic times, reaching a high latitude in Triassic times and substantially the present pole position in Cretaceous times. The measurements on the Arizona strata give a similar picture. As is seen from the Devonian pole position given in Table 1, it seems possible that the motion of the pole was not smooth: in fact, it may have been rather like a random walk. It is thus impossible to tell at this stage whether the discrepancies between the pole positions inferred from 'contemporaneous' strata in Great Britain and Arizona are due to systematic errors or to the strata not being truly contemporaneous. The most serious discrepancy is that of the Permian strata; but the British measurements are at present restricted to a

Table 1. Comparison of Pole Positions deduced from Palæomagnetic Measurements in Europe and Arizona

| Era | Period and age | Europe | | Colorado Plateau | |
|---|---|---|---|---|---|
| | | Formation | Position of N. Pole | Formation | Position of N. Pole |
| Tertiary | Miocene (20 million yr.) | Icelandic basalts (J. Hospers's data) | 81° N. 171° E.<br>(18°, 16°) | | |
| Mesozoic | Cretaceous (80 million yr.) | | | Dakota sandstone | 76° N. 127° E.<br>(11°, 9°) |
| | Triassic (150 million yr.) | Keuper marl (Clegg, Almond and Stubbs's data, ref. 4) | 47° N. 122° E.<br>(18°, 7°) | Springdale sandstone (Zion Canyon) | 60° N. 110° E. |
| Palæozoic | Permian (200 million yr.) | Exeter traps (K. M. Creer's data) | 43° N. 162° E. | Supai shales (Grand Canyon) | 23° N. 119° E.<br>(8°, 6°) |
| | Carboniferous (250 million yr.) | Sandstones and siltstones in Derbyshire (J. C. Belshe's data) | 36° N. 137° E. | Naco sandstones | 49° N. 120° E.<br>(4°, 4°) |
| | Devonian (300 million yr.) | Old Red Sandstone (K. M. Creer's data) | 34° N. 156° E.<br>(10°, 5°) | | |
| Pre-Cambrian | Late Pre-Cambrian (about 600 million yr.) | Torridonian (E. Irving's data) | 5° S. 131° W.<br>(8°, 5°) | Hakatai shale (Grand Canyon) | 30° N. 148° W.<br>(10°, 9°) |
| | | Longmyndian (K. M. Creer's data) | 2° N. 118° W.<br>(13°, 7°) | | |

few lavas which may not span a sufficient time to eliminate the effects of the geomagnetic secular variation, which temporarily causes considerable divergences from an axial field.

It may be concluded that strong evidence now exists that considerable polar wandering has occurred throughout geological time. These results appear to dispose of the possibility that since pre-Cambrian times the continents of America have drifted any appreciable distance from the continents of Europe and Africa. Whether any such continental drift has occurred must await refinement of the accuracy of the measurements. I am indebted to Mr. G. Turnbull and Mr. J. C. Belshe for much help in the measurements and computations.

Details of this work will be published in the *Bulletin of the Geological Society of America*.

## Palæomagnetic Measurements of the Keweenawan

RECENTLY, it has been possible to collect specimens from the Keweenawan system and measure their directions of magnetization. This system is a thick sequence of late Pre-Cambrian volcanics and sediments which outcrop along the margins of the Lake Superior syncline. It is divided into three series, Lower, Middle and Upper Keweenawan. At the type locality on the Keweenawan Peninsula, where most of the specimens were collected, only the Middle and Upper series are represented. Here the Middle Keweenawan consists of 11,000 ft. of basalt and andesite flows known as the Portage Lake Lava Series. There is a total of about three hundred successive flows with occasional interstratified layers of rhyolitic conglomerates and thin beds of sandstone. Succeeding the Portage Lake Lava Series conformably is the Upper Keweenawan, which consists of three divisions. The lowermost is the Copper Harbor Conglomerate, which consists principally of very coarse conglomerates and subordinate amounts of coarse reddish sandstone, but there are also some 500 ft. of interbedded lava flows. The total thickness of the Copper Harbor Formation is 4,500 ft. Lying conformably above the Copper Harbor is the Nonesuch Shale, which in this region consists of 700 ft. of thin bedded sandstones and siltstones. It grades upward into the third of the three divisions of the Upper Keweenawan, the Freda Sandstone. This formation consists of reddish, fine-grained sandstones and siltstones. It is well bedded and consolidated, and usually only shows cross-bedding on a very small scale. One can find ripple marks, mud cracks and raindrop imprints, which clearly indicate a terrestrial deposition. On the Keweenawan Peninsula the Freda Sandstone is approximately 2,500 ft. thick, but in other localities it may reach a thickness of as much as 12,000 ft.

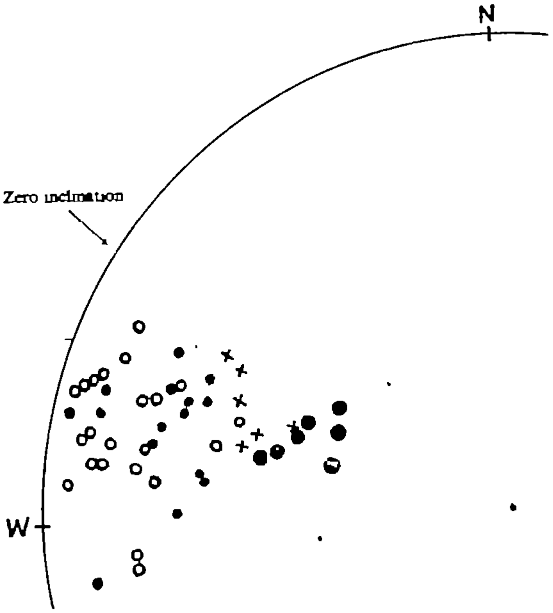

Fig 1. ●, North pole downwards for Freda and Nonesuch; ○, north pole upwards for Freda and Nonesuch; ×, north pole downwards for sandstones in Copper Harbor; ○, north pole downwards for lavas of Copper Harbor and Portage Lake

The structure of the Keweenawan System in this general region is very simple. It is a monocline the eastern boundary of which is marked by the Keweenawan Fault and which disappears under Lake Superior to the west. The strike is north-north-east and the dip ranges from 60° near the fault to 20° close to the shore of the lake. Although the samples were mostly collected from the Keweenawan Peninsula, some specimens were taken near Freda some twenty-five miles to the south-west, where the strata are practically flat-lying. Furthermore, a limited number of samples were collected along the Montreal River, which forms the boundary between Wisconsin and Michigan about a hundred miles to the south-west. Here the strata are steeply tilted with a dip of 70°–80°.

The results of preliminary measurements, corrected for geological dip, are shown in the accompanying portion of a stereogram (Fig. 1). So far, only a small number of specimens have been measured, but one can see that the directions are quite consistent with one another.

The first fact that one notices is that the directions of magnetization are quite different from that of the present earth's field. The second is that the inclinations and, to a much lesser degree, the declinations of the lavas are different from those of the sediments. The first is interpreted as a shift in the geographical pole, in much the same manner as Creer, Irving and Runcorn[1] have interpreted their results obtained from the measurements of pre-Tertiary rocks of Great Britain. For the results from the Nonesuch and Freda formations the pole has been calculated to have been in the Pacific Ocean at long. 165° E., lat. 20° N. Creer[1] has calculated a pole for Lower Cambrian time based on his measurements of the Caerfai Series in Wales, and this pole is located at long. 170° E., lat. 15° N. Thus one can see that there is close agreement between the two, and this agreement suggests the upper part of the Keweenawan is very close to Lower Cambrian in age. This suggestion has often been made by geologists familiar with this region[2].

One would be tempted to attribute the smaller magnetic inclinations of the sediments to the action of sedimentation and compaction. This certainly seems to be the case in the Copper Harbor Conglomerate sandstones, which show an inclination approximately 10° smaller than the lavas above and below them. However, it is difficult to see how these processes could create two almost equal groups of positive and negative dips, which one finds for the formations above the Copper Harbor. Since the mean inclination for the upper sedimentaries is almost 0°, one would expect processes of sediments to have had little or no effect on the value of this mean inclination. Thus it seems that the Copper Harbor sandstones have an inclination smaller than the lavas because sedimentary rocks are unable to reproduce moderate inclinations, but that the mean inclination of the overlying Nonesuch and Freda formations is a true representation of the field at that time. This interpretation means that between Copper Harbor time and Nonesuch time the inclination of the magnetic field changed about 40°, corresponding to a shift of the poles 25° westward. Therefore if the polar wandering was slow and continuous, quite a long period of non-deposition must be represented by the conformable contact of the Nonesuch and Copper Harbor formations. On the other hand, there may have been a sudden and quick change of the pole and continuous deposition.

# Circular Polarization of Gamma-Rays following Polarized Neutron Capture

An experiment has been carried out in order to verify that the capture of polarized thermal neutrons may result in the emission of circularly polarized γ-rays, as first proposed by O. Halpern[1]. It can be hown that neither linear polarization nor anisotropic distribution of the γ-radiation can result from the reaction[2].

For total neutron polarization, the degree of left circular polarization of the γ-rays emitted in the direction of the neutron spin is[3]:

$$P_r = 2\,(J_c - J_i)\,\frac{L\,(L+1) + J_c(J_c+1) - J_f(J_f+1)}{L\,(L+1)\,(2\,J_i+1)} \quad (1)$$

where $J_i$, $J_c$ and $J_f$ are initial, compound and final pins of the neutron and $L$ is the multipole order of he γ-ray. If $J_i$ and $P_r$ are exactly known, it will, n most cases, be possible to determine $J_c$, $J_f$ and $L$ unambiguously.

The properties of the γ-ray polarization analyser are given by the left circular polarization, $P_\gamma$, of the outgoing beam when the incident beam is unpolarized. The γ-ray intensity measured during the experiment is:

$$I_\gamma = c(1 + P_n P_r P_\gamma) \quad (2)$$

where $P_n$ is the polarization of the neutrons being aptured in the $(n,\gamma)$-target and $c$ is a constant.

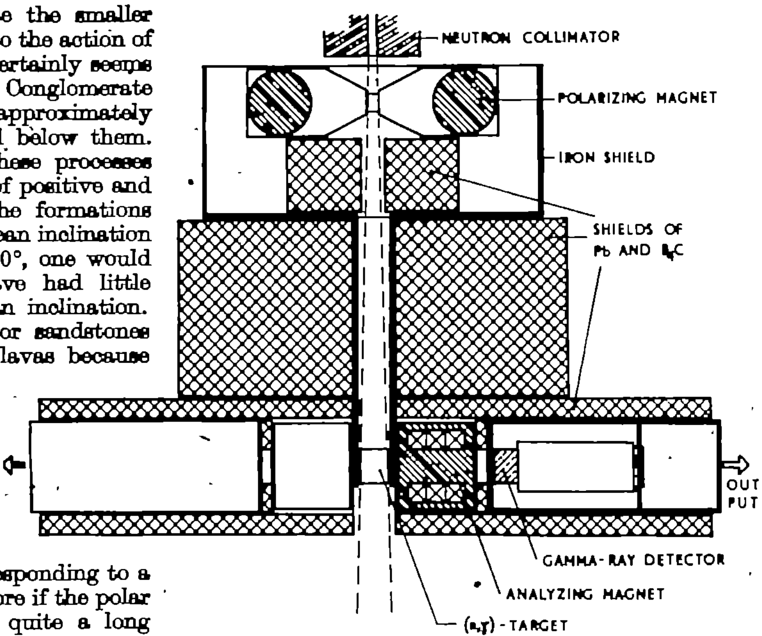

Fig. 1

The experimental arrangement is shown in Fig. 1. Thermal neutrons from JEEP are collimated and partially polarized by transmission through 18 mm. of strongly magnetized iron. The polarized beam falls upon the $(n,\gamma)$-target. γ-Rays are detected by two sodium iodide (thallium) crystals after transmission through pieces of iron 8 cm. long magnetized in the direction of transmission. The total cross-section for magnetized iron is a function slowly varying with γ-energy and dependent upon magnetization direction[4]. At magnetic saturation the cross-section for 8-MeV. circularly polarized γ-rays is:

$$\sigma = \sigma_0\,(1 \pm 0{\cdot}0145) \quad (3)$$

where $\sigma_0$ is the ordinary cross-section and the sign depends upon whether magnetization is parallel or antiparallel to the propagation vector.

During the measurements, $P_n$ was kept constant, and $P_\gamma$ was changed every third minute by reversing the current in the analyser magnets.

Four different γ-rays were studied, all of high intensity compared to the rest of the spectrum and all representing transitions to the ground-state or to a very low-lying state. Therefore, no great difficulties were encountered in selecting them by discrimination. Still, disturbing effects like background and scattering in the target were large. Great care had to be taken in order to make the sensitivity of

Table 1. Data for the Four Gamma-Rays Studied

| Target nucleus | $E_\gamma$ (MeV.) | Known spin values | | | | Observed $\lvert P_n \rvert . P_r$ | Derived |
|---|---|---|---|---|---|---|---|
| | | $J_i$ | $J_c$ | $J_f$ | $L$ | | |
| $^{63}$Cu | 7·91 | 3/2 | | 1 | 1 | 0·061 ± 0·027 | Gamma-ray mainly from $J_c = 2$ |
| $^{56}$Fe | 7·64 | 0 | 1/2 | | 1 | 0·063 ± 0·050 | $J_f = 1/2$ |
| $^{64}$Zn | 7·88 | 0 | 1/2 | | | −0·050 ± 0·042 | $J_f = 5/2$, $L = 2$ or<br>$J_f = 3/2$, $L = 1$ |
| $^{58}$Ni | 9·00 | 0 | 1/2 | 3/2 | 1 | −0·026 ± 0·030 | |

the photomultiplier independent of the polarizing and the analysing magnetic fields. As the polarizing effect is very small, several months of continuous measurements were required to obtain the results quoted in Table 1.

The 'known spin values' are found from nuclear shell theory and from measurements by Kinsey and Bartholomew[5]. No exact measurement of $P_n$ has been made, but it is estimated to be about 8 per cent. The errors given are mainly due to statistical variations. It is clear from these measurements that only the sign of $|P_n| . P_\gamma$ can be quoted with certainty. However, for the simple cases considered, this sign was sufficient for the determination of a few properties by use of equation (1). These are given in the last column of Table 1. The capture in nickel-58 serves as a test for the method.

Work is being carried on in order to improve the experimental arrangement.

## Hydromagnetic Waves in Ionized Gas

RECENT theoretical studies of hydromagnetic (or magneto-hydrodynamic) disturbances in ionized gas suggest that they may play a major part in the physics of some stellar atmospheres and interstellar *HII* regions. Such disturbances, including shock as well as weak hydromagnetic waves, provide a likely explanation of flares, coronal heating and other solar phenomena; their application to the theory of cosmic ray formation is well known.

Previous studies of hydromagnetic disturbances have, for simplicity, assumed a medium with perfect[1,2] or isotropic[3] conductivity. This assumption hides the nature of the electromagnetic field associated with the mechanical disturbance and so fails to reveal some of the most important properties of the phenomenon. Aström[4] and Ginzburg[5] have made further extensions but at the cost of introducing alternative restrictions.

There is a fundamental equation describing the electromagnetic field in a moving isotropically conducting medium (see, for example, ref. 6, equation 2.6 *et seq.*). It includes, among other special cases, the wireless 'telegraph' equation and leads directly and simply to hydromagnetic waves. A corresponding equation for weak disturbances in anisotropically conducting media has now been derived[7]. When only electron conductivity is important and displacement current is neglected it has the form

$$\nabla^2 \mathbf{H} = 4\pi\sigma_3 \left\{\frac{\partial \mathbf{H}}{\partial t} - \text{curl}\,(\mathbf{v}\times\mathbf{H})\right\} + \frac{\sigma_2}{\sigma_1}\frac{\partial}{\partial z}\,\text{curl}\,\mathbf{H}$$

The steady magnetic field $\mathbf{H}_0$ is parallel to the $z$ axis, and the conductivity components $\sigma_1$ and $\sigma_2$ (Hall conductivity) are perpendicular to $\mathbf{H}_0$ and to one another; $\sigma_3 \equiv \sigma_1 + \sigma_2^2/\sigma_1$ and for the gas concerned $\sigma_3 = \sigma_0$ the conductivity along $\mathbf{H}_0$. When heavy ions contribute to the conductivity (as in ionospheric region *E*) a term in $(1 - \sigma_3/\sigma_0)$ is added. This equation has been used to develop a theory of weak hydromagnetic waves somewhat analogous to the well-known magneto-ionic theory of radio waves.

Three distinct hydromagnetic waves may, in general, be propagated[2]. Two of these, which we call the ordinary (*O*) and extraordinary (*E*) hydromagnetic waves, are identical with the two corresponding radio waves found in the magneto-ionic theory. The latter are limiting cases, when heavy-ion motion becomes unimportant. The third wave resembles a sound wave and is called the *S* wave. The properties of the three waves depend on the relative intensities of the 'magnetic pressure' $H_0^2/8\pi$ and the gas pressure $p$ and are briefly described for the two conditions

$$\frac{H_0^2}{8\pi} \gg p \text{ and } \frac{H_0^2}{8\pi} \ll p$$

A right-handed system of axes has $Oz$ along the steady magnetic field and the wave normal in the $xz$ plane at an angle $\theta$ to $Oz$. The angular frequencies of the wave and the heavy ions (gyrating in the magnetic field) are $\omega$ and $\Omega$ respectively.

(1) $H_0^2/8\pi \gg p$. The velocities and polarizations of the *O*- and *E*-waves are complicated functions of $\theta$ and $\omega/\Omega$. When $\omega/\Omega \ll 1$ the velocities are $V \cos \theta$ and $V$ respectively, where $V^2 = H_0^2/4\pi\rho$ and $\rho$ is the gas density. The waves are then nearly plane polarized along $Oy$ and $O\zeta$ (in the phase plane and perpendicular to $Oy$). They are only circularly polarized[5] for vanishingly small values of $\theta$. The electric polarization is such that $E_z \sim 0$ and $E_x/E_y \sim H_y/H_x$. The Poynting vectors are nearly along $Oz$ and the wave normal. The gas velocity components are $v_z = 0$ and $v_y/v_x = \cos^2\theta' H_y/H_x$, movement being in elliptical orbits.

The third or *S*-wave has velocity $U \cos \theta$, where $U$ is the velocity of sound. The magnetic and electric perturbations are nearly along $O\zeta$ and $Oy$, the Poynting flux along the wave normal and the gas velocity along $Oz$.

(2) $H_0^2/8\pi \ll p$. When $\omega/\Omega \ll 1$ both the *O*- and *E*-waves have velocities $V \cos \theta$ and are circularly polarized. The electric field is given by $E_z \sim 0$ and $E_x/E_y = \pm i \cos \theta$ and the Poynting vectors rotate on a cone touching $Oz$ and the wave normal. The gas velocity vectors lie in the phase planes, rotating with constant amplitude in the same direction and in contraphase with the magnetic vectors.

The *S*-wave has velocity $\sim U$ and magnetic and electric vectors along $O\zeta$ and $Oy$ respectively. The Poynting flux and gas velocity are along the wave normal, the wave being in effect a slightly disturbed sound wave[3]. In all the waves described above the absorption is determined by $\sigma_3$ ($\equiv \sigma_0$) rather than $\sigma_1$ or $\sigma_2$.

The results given above have been extended to strong (or shock) hydromagnetic disturbances, which will be discussed elsewhere.

## Expansion and Deterioration of Ceramic Bodies

DURING an investigation of local occurrences of expansion of brickwork and deterioration of roofing tiles we have found that:

(1) Kiln-fresh bricks and tiles taken from representative works in Melbourne all expanded irreversibly on exposure to moisture or even to the atmosphere. Bricks expanded linearly on soaking in water from 0·04 to 0·18 per cent, and tiles on autoclaving from 0·08 to 0·57 per cent.

(2) The degree of expansion, which is characteristic of each brick or tile works, apparently depends not so much on the firing temperature (although the rate of expansion is greater in bricks fired at lower temperatures) as on the composition of the raw material. Cream bricks and light-coloured tiles, both richer in kaolin, expanded more than dark ones.

(3) Tiles in use deteriorate predominantly on protected parts, for example under overlaps, which remain moist for long periods. After years of service they contain about 0·7 per cent of water lost above 110° C., which is of the same order as that of the autoclaved tiles.

(4) The small amount of sodium (0·32–0·52 per cent) present in unaffected tiles is largely, if not completely, replaced by calcium in affected parts.

(5) One badly deteriorated tile, about thirty years old, contains a crystalline calcium zeolite.

(6) The type of tile and brick which deteriorates most in use is similar to that which expanded most in our experiments.

That ceramic bodies expand on contact with water is no new observation, for expansion of bricks[1,2], structural tiles[3], sewer pipes[3] and other ceramic bodies[4] has already been reported. Keppeler and Aurich[5] concluded from indirect evidence that the expansion on rehydration of whiteware fired above 950° C. was due to the formation of permutites (amorphous zeolites). Hill[6], when studying the rehydration of fired clay minerals, identified a crystalline zeolite in rehydrated sodium vermiculite. In the X-ray diffraction patterns of some of the other materials he found weak, extra, unidentifiable lines from which he inferred the presence of poorly crystalline zeolites. It is significant that the temperature (1,050° C.) at which Hill found the greatest expansion of kaolinite (after destruction of its lattice) is close to that (approximately 1,060° C.) at which Delimarskii[7] prepared substances from various mixtures of soda, kaolin and quartz, which disintegrated on hydration and formed permutites. These results indicate that glassy material that is found in well-fired ceramic bodies is likely to form permutites on rehydration, particularly when originating from kaolinitic clays containing soda. The glass expands on forming permutite, when water is incorporated in its structure as hydroxyl ions, and this may cause local stresses. These stresses can lead to disintegration, as we have shown by the autoclaving of soda glass which in hydrating (up to 13·8 per cent water) expanded markedly, but disintegrated so badly that the expansion could not be measured.

The presence of permutites, which have a high cation-exchange capacity, would explain the replacement of sodium by calcium in the deteriorated tiles. The introduction of the slightly larger and more highly hydrated calcium ion into the permutite would cause a secondary expansion of the body such as has been found[2] with bricks, which expanded 0·20 per cent in a solution of a calcium salt compared with 0·05 per cent in water.

We conclude that the expansion on rehydration of ceramic bodies burnt above 950° C. is due to the formation of zeolites, mainly of permutites. The ceramic body may deteriorate as a result of expansion in extreme cases, or as a result of frost or salts attacking the already weakened body.

It has been shown that the irreversible expansion can at least be reduced by the addition of lime[2] or magnesite[4] to the raw clay, and it is likely that barium carbonate also would stabilize the fired body. 'Curing' bricks by stacking them in the open for some time should prevent or greatly reduce expansion after laying. These matters are being investigated.

We are grateful to Drs. J. S. Hosking and W. F. Cole and to Mr. R. D. Hill for their valuable discussions.

## Stillwellite, a New Rare-Earth Mineral from Queensland

THE presence of stillwellite was discovered in 1954[1] during a mineralogical investigation of radioactive ore from the Mary Kathleen Lease, 34 miles east of Mt. Isa in north-western Queensland. At the Lease, stillwellite and allanite occur in quantity, along with garnet and other minerals, as a metasomatic replacement of metamorphosed calcareous sediments. Uraninite is dispersed through both minerals.

Stillwellite is the major constituent of sections of the ore, occurring as crystals up to 5 mm. in diameter. In thin section it is colourless with a birefringence of 0·018–0·020, and is uniaxial positive to biaxial positive with $2V$ up to 6°. Occasional zoning is evident in thin sections and in the variation of the refractive index of the ordinary ray from 1·775 to 1·784 ± 0·003 in sodium light. The stillwellite is thus optically comparable with cerite, from which it differs in having lower refractive indices, and a different X-ray powder pattern.

The preliminary analysis of a concentrate containing 96–98 per cent stillwellite totals 100·30, and gives as major constituents $Ln_2O_3$ 58·4, $B_2O_3$ 11·5, $SiO_2$ 20·1, CaO 3·96, $P_2O_5$ 2·58 per cent. Cerium oxide ($Ce_2O_3$) constitutes 51 per cent of the total lanthanon oxide, which contains not more than 5 per cent of heavy lanthanons.

An X-ray single-crystal study shows that stillwellite is hexagonal, rhombohedral, with space group $C3m$, $C3_22$ or $\bar{C}3m$, a unit cell of dimensions

$a = 6\cdot85$ A, $c = 6\cdot64$ A., and an axial ratio $a:c$ of 1·032. Allowing for the presence of a small amount of a phosphate mineral in the concentrate analysed, this cell contains close to 3(Ln,Ca)BSiO$_5$ for the measured density of 4·57 gm./c.c.

The mineral is named in honour of Dr. Frank Leslie Stillwell, former chief of the C.S.I.R.O. Mineragraphic Investigations, who has contributed so notably to the knowledge of Australian ore deposits and who initiated the study of ore minerals in Australia.

A detailed report will be published elsewhere.

From another source, the discovery of a "boron-bearing variety of cerite" in Mary Kathleen ore was announced in the Adelaide *News* of May 20, 1955.

## Plasticity of Wool

The marked variations in plasticity among the fibres of a single staple of wool[1] are now known to be associated with the types of follicle from which they are derived, fibres with the lowest plasticity being produced by primary central follicles, which are the first to develop, and fibres with the highest plasticity by the secondary follicles which are the last to develop[2]. It has, however, proved more difficult to identify the chemical and physical causes of the variations in plasticity. With two wools, which were examined in great detail, fibres with the lowest plasticity were found to have the highest sulphur content, and vice versa[1,2], as would be expected if unfolding of the main chains of α-keratin during plastic flow is impeded by cystine cross-linkages; but the simplicity of the relationship appears to be marred in other cases by differences in the mode of distribution of cystine in different fibres.

A rule of more general validity has, however, emerged from studies of the relationship between the plasticity of fibres and the proportion of ordered (crystalline) material they contain. The observation that there is an inverse relationship between plasticity and crystallinity in the case of New Zealand Lincoln wool[3] has now been confirmed with a wide range of New Zealand Romney, Australian merino and South African merino wools. Not only so, but also the physical and chemical causes of variations in plasticity among the fibres of a single staple appear to be linked, as is shown by the following determinations of the plasticity and tyrosine content of fibres from single staples of two New Zealand Romney wools.

Fibres from primary lateral follicles (early curly-tips) and secondary follicles (long histerotrichs) were selected from a single staple in the usual way[2]. Each fibre was allowed to extend about 55 per cent in water at 22·2° C. under a load of 700 kgm./cm.$^2$. On being released, the fibre returned to its original length, and its plasticity ($k$) was calculated from the extension/time curve[1]. The eight early curly-tips with the lowest plasticities and the eight histerotrichs with the highest plasticities were then iodinated with iodine-131 under conditions which are known to convert almost all (96 per cent) of the tyrosine side-chains into 3 : 5-di-iodotyrosine[4]. After the fibres had been freed from loosely combined iodine by treatment with sodium thiosulphate solution and washing, radio-photographs were prepared in the usual way[4]. The tyrosine content of each fibre was then estimated by measuring the optical density of the radiophotograph at intervals along the length and correcting for the variations in cross-sectional area of the fibre. The results are given in Table 1.

Table 1

| Wool No. | Type of fibre | Average diameter ($\mu$) | Average plasticity, ($k \times 10^{-4}$) | Tyrosine content (arbitrary units) |
|---|---|---|---|---|
| 1 | Early curly-tips | 40 7 | 28 7 | 6·4 |
|  | Long histerotrichs | 28·8 | 67·6 | 10·9 |
| 2 | Early curly-tips | 39·0 | 49·7 | 6·1 |
|  | Long histerotrichs | 28 4 | 77·9 | 9·0 |

In both cases the more plastic fibres contain the greater amount of tyrosine, and since the more plastic fibres are also the more amorphous, it seems clear that the bulky side-chains of tyrosine are one cause of main-chain disorder in wool, just as in the case of silk.

## Theory of Antibiotic Inhibition Zones in Agar Media

Since Cooper and Woodman[1] proposed on theoretical grounds that the formula

$$x^2 = 4\,DT_0\,2\cdot30\,(\log m_0 - \log m')$$

should explain the size of inhibition zones, under specified experimental conditions, evidence on the validity of this proposal has been accumulated by many workers. The variables in the formula have been further analysed, and it is now possible to give an extended explanation of their meaning, which should give a more accurate understanding of the factors influencing the size of inhibition zones.

The original formula was concerned with the diffusion of an antibiotic having a diffusion coefficient $D$, from a solution kept at a constant concentration $m_0$, into an agar culture of an organism (Fig. 1). The time at which the critical concentration $m'$ reached the edge of the zone of inhibition can be

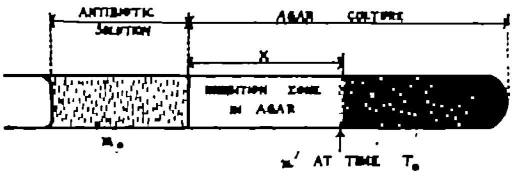

Fig. 1

alculated for all values of $x$ (zones of different sizes) and is given by

$$T = x^2/4\,(D\;2\cdot30 \log m_0/m') \qquad (1)$$

It was shown experimentally that a critical value of $T$ existed in the growth of the bacterial population, when the edge of the zone was formed; for if the organism is incubated for $h$ hr. before adding the diffusing antibiotic, the size of the zone is reduced. This critical value was called $T_0$, because if the time of preincubation of culture $h$ is $T_0$, the zone was reduced to nil. The size of zones for varying values of $h$ was given by putting $T = (T_0 - h)$ in (1), and when $h = 0$, $T = T_0$.

Cooper and Linton[2] examined the factors influencing $T_0$, and showed the importance of temperature control in the early hours of growth. They explained experimental anomalies in the use of plate cultures. Temperature control was much more certain by using the tube method of Mitchison and Spicer[3], and therefore Cooper and Gillespie[4] used this method to investigate its influence on $T_0$, in the case of streptomycin acting on staphylococcus. Over a wide range (22°–42°) the variation in $T_0$ from 2·2 hr. to 9·0 hr. was explicable by:

$$T_0 = L + n'G \qquad (2)$$

where $L$ is the lag period, and $G$ the generation time of the organism in the nutrient medium at the temperature of the experiment; $n'$, the number of generations at time $T_0$, was remarkably constant (3·5–4·4) over the whole temperature range, when a standard inoculum and a standard medium were used.

Cooper[2] pointed out that the slope of the graphs of Mitchison and Spicer[3] with different sizes of inocula were empirically related to the inoculum size ($N_0$). Though the relationship suggested with $\sqrt{N_0}$ was only an approximation without theoretical foundation, it prompted us to examine this more closely. As a result, it is now possible to give a theoretical basis to the meaning of $T_0$ and calculate its value from the growth curve of the organism. The effect of inoculum size observed by Mitchison and Spicer[3], and further investigated by Linton[5], can be even more accurately predicted.

The theory of the early part of the growth curve is well known. Let $N$ be number of organisms at time $T$, $N_0$ their number at zero time, $n$ be the number of generations, $G$ be the generation time. Then $N = N_0\, 2^n$ and $T = L + nG$.

In solid media, the number of organisms per colony is given by $p = N/N_0 = 2^n$, or $n = \log_2 p = \log_2 N/N_0 = 3\cdot32 \log_{10} N/N_0$. Therefore, $T = L + 3\cdot32\, G\,(\log N/N_0)$. When $T = T_0$, let the value of $N$ be $N'$ and the value of $n$ be $n'$. Then

$$T_0 = L + n'\,G = L + 3\cdot32\, G\,(\log N'/N_0) \qquad (3)$$

The first part of this equation is identical with equation (2), which was derived experimentally. It is now evident that $n'$ is the number of generations required to reach a critical density of organisms per ml., and that $T_0$ varies with both temperature and size of inoculum to allow this to be done.

Combining equation (3) from the growth-curve of the organism with equation (1) from the diffusion laws, we have:

$$x^2/4D\,(2\cdot30 \log m_0/m') = T_0 = L + 3\cdot32\, G\,(\log N'/N_0)$$

or

$$x^2 = 4\,D\,(2\cdot30 \log m_0/m')\,(L + 3\cdot32\, G \log N'/N_0)$$

This explains the effects of inoculum density, so long as allowance is made for the possible effect of high values of $N_0$ on lag period and generation time (not detectable in Mitchison and Spicer's results). The values $m'$ and $N'$ depend on the antibiotic and the organism, but the other symbols represent variables all of which can be separately determined and controlled. Even $D$ depends on the viscosity and temperature. It is felt, therefore, that the critical density of organisms $N'$, which represents a limiting factor for inhibition of growth, is just as important as the critical concentration of antibiotic $m'$, which must be reached before $N'$, in order to form a zone. The critical time $T_0$ is the time required by the inoculum $N_0$ to multiply at a rate of $1/G$, in order to reach the population $N'$. The edge of the zone at distance $x$ is decided by the fact that the critical concentration $m'$ must reach there before the bacterial population exceeds $N'$. The amount of bacterial cells is evidently just as important as the amount of antibiotic.

The theory, with appropriate modifications, should be applicable to zones of exhibition in vitamin assay work, as well as zones of inhibition due to antiseptics. An understanding of its principles should enable the detection of other factors influencing results to be made more easily (for example, variations in the sensitivity of the organism; the influence of nutritional and toxic factors in the medium; antagonism and synergism with other substances). In the case of streptomycin and the staphylococcus, the presence of magnesium and iron ions in the agar medium influenced the critical concentration $m'$ and hence the size of the zones (Linton[6]). With constant medium, however, $m'$ and $N'$ have been constant, within the experimental error, for the action of streptomycin on staphylococcus, for all temperatures and all densities of inoculum. With chloramphenicol, temperature affects the action of the antibiotic, giving a change in $m'$—and possibly $N'$ may be slightly affected, though the result is on the borderline of the experimental deviations.

## Effect of Anti-histamine Substances on Cold Vasodilatation in the Finger

LEWIS[1] described an intermittent vasodilatation in the finger during its immersion in cold water, and suggested that a histamine-like substance was released in the cold tissues.

In order to study the part played by histamine in bringing about this response, the antihistamine substances diphenhydramine hydrochloride ('Benadryl') and promethazine hydrochloride ('Phenergan') were administered to normal, heat-acclimatized, Asian subjects, whose cold vasodilator responses were followed by means of copper-constantan thermocouples strapped to their index fingers. In each case the skin temperature of the finger was plotted against

Table 1

| Treatment | No. of subjects | Area of cutaneous histamine wheal (sq. mm.) | Graphic representation of cold vasodilator response (sq. cm.) | Treatment | No. of subjects | Area of cutaneous histamine wheal (sq. mm.) | Graphic representation of cold vasodilator response (sq. cm.) |
|---|---|---|---|---|---|---|---|
| Dummy by mouth | 4 | 11·4 | 37·5 | 'Benadryl' (50 mgm.) by mouth | 4 | 8·5 | 37·8 |
| Dummy by mouth | 7 | 10·8 | 43·8 | 'Phenergan' (50 mgm.) by mouth | 7 | 3·9 | 25·6 |
| Iontophoresis of 0·9 per cent saline | 3 | — | 46·9 | Iontophoresis of 2·0 per cent 'Phenergan' | 3 | — | 57·5 |

time and the results expressed (1) as the mean area enclosed by this curve[2], and (2) as the latent period of the response[3]. A 1/1,000 solution of histamine acid phosphate was placed on the skin of the forearm of the same subjects and a needle-prick was made through the solution. The mean area of the wheal thus produced was measured immediately before each cold immersion.

The results are given in Table 1. 50 mgm. of diphenhydramine hydrochloride, by mouth, reduced the size of the cutaneous histamine wheal ($t = 2·21$, $p < 0·20 > 0·10$) but had no effect on the cold-vasodilator response. 50 mgm. of promethazine hydrochloride given by mouth caused a highly significant reduction both of the histamine wheal ($t = 11·473$, $p < 0·001$) and of the cold vasodilator response ($t = 3·831$, $p < 0·01 > 0·001$) and it also significantly delayed the onset of the vasodilator response ($t = 3·628$, $p < 0·01 > 0·001$). There was a reflex vasodilator reaction in the index finger of the opposite hand, and this response was also significantly delayed by the oral administration of 50 mgm. of promethazine hydrochloride ($t = 3·357$, $p < 0·02 > 0·01$). When introduced into the finger-tip by iontophoresis, promethazine hydrochloride increased the magnitude of the cold vasodilatation, a result compatible with the local anæsthetic action of promethazine hydrochloride[4,5]. In ten untreated subjects a negative correlation was found between the size of the cutaneous histamine wheal and the magnitude of the cold vasodilatation ($r = 0·705$, $p < 0·05 > 0·02$).

Since systemic administration of promethazine hydrochloride causes central depression[6,7], and since local administration of promethazine hydrochloride did not inhibit the cold vasodilator response, it seems possible that inhibition of the response by the oral administration of 50 mgm. of this drug was due to a central depressant action. These results provide, therefore, no definite evidence for the participation of histamine in the cold vasodilator-response, and this conforms with observations by Duff *et al.*[3].

Experiments are now in progress to investigate the effect of drugs with a central depressant action on the cold vasodilatation in the finger.

## Effect of Vagal Stimulation on the Sinus Venosus of the Frog's Heart

The effect of vagal stimulation or applied acetylcholine on electrically driven heart auricle fibres ha been studied with intracellular electrodes by severa workers[1]. The purpose of the present experiment was to gain some information about the events durin vagal inhibition in spontaneously active pacemake fibres.

The sinus venosus of a frog's heart was excise together with the two vago-sympathetic nerves, cu open and pinned out. When an electrode was inserte into the region where the beat could be observe to start, a typical pacemaker potential[2] was seen the membrane potential decreases slowly throughou diastole until the threshold for an action potentia is reached. In fibres that showed constant picture for several beats, the most negative value of th membrane potential during the cycle ranged from 45 to 60 mV.

If the vagi are stimulated briefly during the fallin phase of an action potential, the repolarization proceeds to above the most negative point reached i previous cycles, and the next beat is delayed becaus the slope of the pacemaker potential is reduce (Fig. 1*A*, left). With more prolonged stimulatio a slow 'hyperpolarization' suppresses the next pacemaker potential and stops the heart (Fig. 1*A*, right) On removing the vagal stimulus a slow depolarizatio develops again. In the experiment illustrated, thi depolarization was not allowed to reach the threshold instead, a second train of vagal impulses was sen into the preparation, causing a renewed hyperpolarization. After this procedure was repeated onc more, an action potential of shortened duration aros from a now apparently reduced threshold. Th maximum increase of the membrane potential, a measured from the foot of the last pacemake potential, was 8 mV. in this experiment.

In twelve other experiments, the inhibitory hyperpolarization measured 3–13 mV. (mean 8 mV.). O several other sinus fibres, however, vagal stimulatio merely depressed the pacemaker potential (Fig. 1*B*) This suggests that the transition from a typical pacemaker to a typical auricle fibre is gradual. It i noteworthy that the first two action potentials afte the vagal arrest are not only shortened, but als slightly decreased in amplitude. This reduction o the 'overshoot' amplitude was usually observed and was particularly striking on occasions whe impulses reached the inhibited fibre from a accidentally denervated and still beating part o the sinus.

The events underlying the increase in beat frequenc on sympathetic stimulation were studied in a fe atropinized preparations. As might be expected, th pacemaker potential increased in steepness after latent period of several seconds (Fig. 1*C*). Th

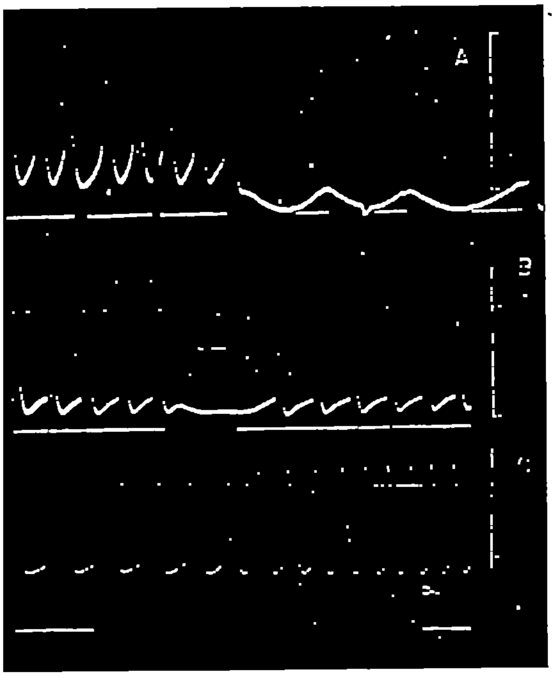

Fig 1 Intracellular records from the sinus venosus of a frog's heart. Vagal stimulation indicated by breaks in the lower beam. (*A*) Vagi stimulated at 10 per sec. during the repolarization of the third action potential. During the eighth action potential, vagal stimulation starts again (see text). Gap after fifth action potential denotes interval of several seconds. (*B*) Depression of pacemaker potential without hyperpolarization This preparation was treated with ergotamine, 1 in 10$^{5}$ (*C*) Effect of vago-sympathetic stimulation in an atropinized preparation.
Voltage calibration in 20 mV steps ; in (*B*) and (*C*) a line is drawn through zero potential, in (*A*) calibration from −10 mV. downwards. Time : 1 sec.

vershoot' was increased from 5·5 mV. to 11 mV. sympathetic stimulation.

These results confirm the results of Gaskell[3], who und that the demarcation potential in turtle auricle as increased during vagal inhibition. They also ll to mind the experiments of Howell and Duke[4], nd of Lehnartz[5], who showed that during vagal rest a heart liberated potassium ions ; for an out-ow of potassium ions could contribute to the hibitory hyperpolarization. An increase in per-eability to potassium, relative to that of sodium, uld also account for a decrease in the 'overshoot' nd for the faster repolarization of the action otential.

## utritive Value of Heated Vegetable Oils

MUCH of the fat consumed by human beings, articularly in India, has been heated, and the con-itions of heating vary widely and also with the ature of the foodstuff into which the oil or fat is icorporated. It is therefore necessary to have scientific data concerning the nutritive value of heated oils and fat.

Heated oils have been shown to be poorly absorbed[1], to produce cancerous tumours[2] and to cause paralysis resembling that due to vitamin E deficiency[3]. Thermal polymerization was found to develop toxic products responsible for growth depression[4]. Kaunitz[5] stated that oxidized fats destroyed vitamins in the diets and thus caused retardation of growth. Chalmers[6] found that injections of heat-polymerized cotton-seed oil did not lead to the growth of tumours.

In most of the above investigations, the oils were heated in a current of carbon dioxide or nitrogen. In India, oils are heated in open pans for long periods and, further, the residual oil from a day's operations is supplemented with fresh oil and re-heated again. This may accelerate the oxidative and other changes. The work reported in this communication was undertaken to elucidate the nutritive value of some of the commonly used oils when they were fed after heating.

Groundnut, sesame and coconut oils were heated in an open iron pan at 270° C. for 8 hr. They were then incorporated into synthetic diets to give 15 per cent fat, and fed to albino rats. There were six groups of six rats each, five weeks old and weighing 40–50 gm. The two groups of rats allotted to any particular oil (unheated and heated) were litter mates and were distributed with due consideration to weight and sex. The diet employed had the following composition : fat, 15 per cent ; casein, 12 per cent ; sugar, 10 per cent ; salt mixture, 4 per cent ; and starch, 59 per cent ; and the vitamin supplements were : thiamine, 15 ; riboflavin, 60 ; pyridoxine, 10 ; niacin, 10 ; calcium pantothenate, 50 (all in mgm. per kgm. of the diet), and choline, 1 gm. Vitamins A and D were given in the form of two drops of 'Adexoline' twice a week per rat. The rats were housed in independent cages. The vitamin supplements were added to the diet every day, so as to prevent their destruction by the heated oils. Weekly growth records were maintained. At the end of the sixth week, four rats from each group were opened under chloroform, and liver, spleen, stomach and kidney were removed and weighed. The liver fat was also estimated. The observations are presented in Table 1.

Table 1. INFLUENCE OF HEATING THE OIL ON ITS NUTRITIVE VALUE AND FAT DEPOSITION IN THE LIVER

| | Average gain per rat per week (gm.) | Feed efficiency | Liver weight as percentage of body weight | Percentage fat in liver |
|---|---|---|---|---|
| Groundnut oil: | | | | |
| Unheated | 13·0 ± 0·5 | 1·1 | 3·8 ± 0·3 | 3·9 ± 0·3 |
| Heated | 5·0 ± 0·9 | 0·67 | 5·7 ± 0·6 | 7·1 ± 0·4 |
| Sesame oil: | | | | |
| Unheated | 10·0 ± 0·8 | 1·0 | 4·2 ± 0·7 | 4·8 ± 0·3 |
| Heated | 4·3 ± 0·7 | 0·7 | 6·0 ± 0·5 | 7·8 ± 0·3 |
| Coconut oil | | | | |
| Unheated | 11·0 ± 1·1 | 1·1 | 4·3 ± 0·3 | 4·5 ± 0·3 |
| Heated | 4·5 ± 0·7 | 0·7 | 5·8 ± 0·4 | 7·0 ± 0·3 |

The results show clearly that in all three cases the heated oil has adversely affected the gain in weight. The feed efficiency, that is, the increase in weight per gm. of fat consumed, of the heated-oil group of rats is considerably reduced. There were no significant changes in the weights of stomach, kidney and spleen of the two groups of animals. These results are not, therefore, presented here.

It may be seen that the liver weights (fresh) of the heated-oil groups are significantly higher than the controls. The fat content of the livers of the heated-oil group is nearly twice that of the control groups. Heated oil has produced fatty infiltration of the liver. Further, the livers were badly damaged and congested, and were not of the normal colour.

When the heated oil was fed at 30 per cent level, all the rats died within a week, whereas the control rats were quite healthy. In another set of trials, when 15 per cent heated oil (heated at 280° C.) was used in the diet, severe jaundice occurred and four of the six rats died in the sixth week of the experiment. The exact changes brought about by heating the oil and also the other aspects of the problem are being studied.

Our thanks are due to Prof. K. V. Giri for his interest in the investigation.

## Cessation of Tillering in Young Grass Plants

DURING the early seedling growth of *Lolium perenne* plants in pots, Cooper[1] noted that the number of tillers per plant increased exponentially with time until some date 60–100 days after sowing, when the initial exponential growth was sharply curtailed and tiller production ceased. This phenomenon has been observed in experiments in which the chief concern was with growth as measured by increase in weigh The results obtained in a field experiment where th plants were growing in a sward are summarized i Fig. 1. In this experiment thirty plants of each twenty-two strains representing seventeen gra species were dug up twice a week, washed free of soi the tillers counted and then dried and weighe Each point in the figure is derived from the measure-ment of 660 plants. In the majority of strains till production ceased about the seventieth day aft sowing. No sudden change occurred in the rate increase of the plants (roots plus shoots) or in th rate of increase of the weight of shoot per tille that is, the weight of a tiller. Other details of th experiment have been published elsewhere[2].

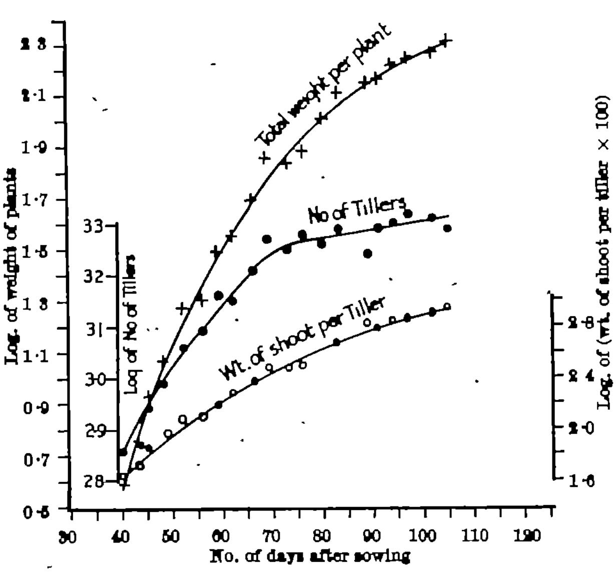

Fig. 1

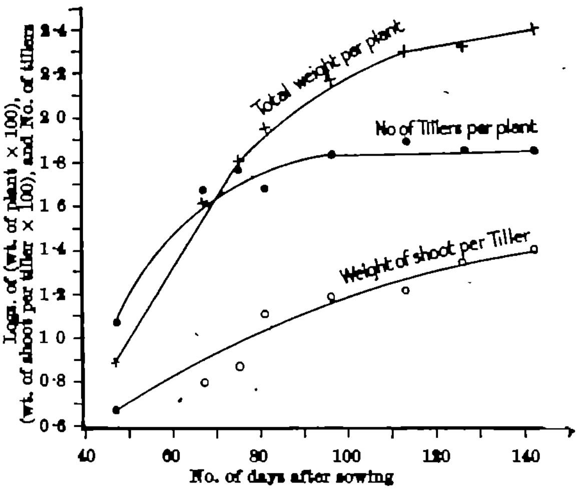

Fig. 2

In another experiment, plants of *Lolium perenne* S.24 were grown in whalehide pots of 6,700 m capacity. An equal number of pots containing on two or three plants were taken at intervals, th plants washed free from soil and then treated as i the other experiment. Usually thirty pots we dealt with on each date. The results are presente in Fig. 2 as the mean of the plants measured on particular date. Tiller production ceased about th hundredth day after sowing. As in the field exper ment, there was no cessation of dry-weight increa comparable to the cessation of tiller productio although a gradual reduction in this rate did occu The weight of shoot per tiller increased at the san rate throughout the period of the experiment.

This state of inanition of tillering would appear affect chiefly the meristematic tissues concerned wi the production of new tillers; the more matu tissues are unaffected and continued to grow, th is, to gain in weight without any sudden change the rate of increase for some considerable time aft the cessation of tiller production. This is in accor ance with Cooper's[3] findings that rate of leaf pr duction on the main tiller was unaffected by cessati of tillering.

## Temporary Destocking of Pastures to aid Control of the Cattle Tick

The tick *Boophilus microplus* Can., is generally considered to be the most serious single cause of loss to the cattle industry in tropical Australia, contributing to the death of many cattle in dry years. Present control measures are costly, and by placing undue reliance on frequent dipping are thought to have increased the tendency of ticks to become resistant to BHC and arsenic[1]. A method involving only two or three dippings per year can be expected to reduce the difficulties of controlling strains of ticks resistant to these and newer acaricides. The results of the following 'pilot-scale' experiment carried out near Rockhampton, Queensland, emphasize the possibility of reducing the frequency of acaricidal treatment by destocking the pastures for periods which some cattle owners do not find inconveniently long.

Two herds of cattle were kept in adjoining comparable paddocks of approximately seventy-five acres. An equal number (10–14) of animals was present in each of the two herds at any one time. The 'control' herd was allowed access to the whole area of paddock *C* continuously, whereas the experimental herd was alternated between the two halves, *A* and *B*, of the other paddock, which was divided by an electric fence. The periods for which the *A* or *B* paddocks were destocked were based, after mid-November 1953, on observations made in the district on the time taken from the date of drop of a replete female tick to the death of its larval progeny (Wilkinson, unpublished data). Fig. 1 shows infestations of adult ticks, exceeding 0·5 cm. in length, on the two herds, the numbers with arrows indicating occasions on which the animals were sprayed with DDT preparation (1 per cent $p,p'$-isomer). It will be seen that, after the beginning of February 1954, infestations of the cattle moved to previously destocked pastures remained low. A few ticks continued to occur on the cattle, and this was considered a desirable feature, because the cattle would be regularly re-infested with *Babesia* carried by the larvæ and thus retain their immunity to 'redwater' fever[2].

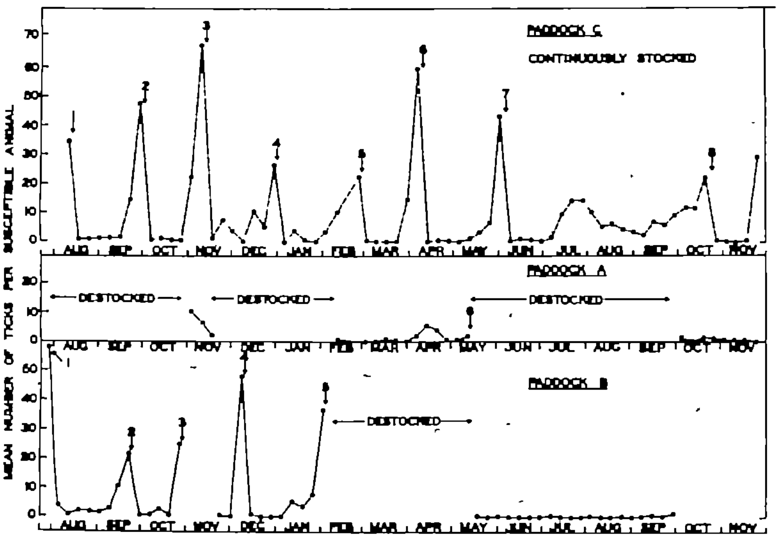

Fig. 1. Comparison of infestations of cattle on a continuously stocked and a pasture spelling paddock. Counts of female ticks, 0·5 cm. and upwards in length, on the right side of the cattle

Destocking of pastures has been practised frequently during tick eradication campaigns, but no experiment on destocking as a control measure has hitherto been described. A fuller account of this work and its application to Queensland conditions will be published elsewhere.

## A New Acaricide, 2,4,5,4'-Tetrachlorodiphenylsulphone

Läuger *et al.*[1], Swingle[2] and Browning *et al.*[3] have stated that the insecticidal value of $p,p'$-dichlorodiphenylsulphone is relatively low; Läuger *et al.*[1] state that diphenylsulphone and monochlorodiphenylsulphone are devoid of any insecticidal activity. On the other hand, Eaton[4] found among various diphenyl compounds some substances with a sulphone link active against spider mites and their eggs; optimal acaricidal activity occurred with mono-$p$-chlorodiphenylsulphone[5].

Diphenylsulphone and mono-$p$-chlorodiphenylsulphone are more or less phytocidal at active concentrations. We have now found that 2,4,5-trichlorodiphenylsulphone ('*V* 17') and 2,4,5,4'-tetrachlorodiphenylsulphone ('Tedion *V* 18') possess strong acaricidal properties without phytocidal side-effects. As can be seen from Tables 1 and 2, the latter substance is more active on the eggs than any of the other compounds listed. As is the case with some newer specific acaricides now in use, such as *CPBS* ($p$-chlorophenyl-benzenesulphonate), *CPCBS* ($p$-chlorophenyl-$p$-chlorobenzenesulphonate) and $p$-chlorophenyl-$p$-chlorobenzylsulphide, 'Tedion *V* 18' also shows activity on all stages except adult spider mites.

The various compounds were tested on *Tetranychus urticae* Koch on bean plants (*Phaseolus*). Potted bean plants with or without eggs were dipped in emulsions containing the active material. After the plants without eggs had dried, these were infected with adult females in order to obtain eggs on the dry residue. After two or three days the adults were removed. In order to evaluate the penetration of 'Tedion' into the leaf, leaves were treated on the upper side and infected with mites on the under side. Solutions and emulsions containing 1,000 and 100 p.p.m. of active material caused in these circumstances a total kill of eggs and larvæ.

The phytotoxic properties of 'Tedion *V* 18' were investigated on seedlings of *Tropaeolum majus*, cucumber, tomato, potato, broad bean (*Vicia faba*), French bean (*Phaseolus vulgaris*) and garden pea (*Pisum sativum*). The plants were thoroughly sprayed with 0·3, 1·0 and 3·0 per cent of active material,

Table 1. Action of *CPBS*, *CPCBS* and 'Tedion' on *Tetranychus urticae* Koch

| Compound | Concentration (p.p.m.) | Percentage kill | | | |
|---|---|---|---|---|---|
| | | Eggs dipped | | Eggs layed on residue | |
| | | Direct kill of eggs | Total kill eggs/larvæ | Direct kill of eggs | Total kill eggs/larvæ |
| *CPBS* | 100 | 24 | 100 | 74 | 100 |
| | 30 | 0 | 100 | 14 | 77 |
| | 10 | 0 | 60 | 0 | 0 |
| *CPCBS* | 100 | 25 | 100 | 58 | 99 |
| | 30 | 7 | 100 | 4 | 38 |
| | 10 | 0 | 33 | 8 | 10 |
| 'Tedion' | 100 | 100 | | 100 | |
| | 30 | 100 | | 100 | |
| | 10 | 100 | | 100 | |

Table 2. Action of *p*-Chlorophenyl, *p*-Chlorobenzylsulphide (Chlorparacide) and 'Tedion' on *Tetranychus urticae* Koch

| Compound | Concentration (p.p.m.) | Percentage kill | | | |
|---|---|---|---|---|---|
| | | Eggs dipped | | Eggs layed on residue | |
| | | Direct kill of eggs | Total kill eggs/larvæ | Direct kill of eggs | Total kill eggs/larvæ |
| Chlorparacide | 100 | 81 | 100 | 100 | |
| | 30 | 64 | 99 | 100 | |
| | 10 | 45 | 72 | 87 | 97 |
| | 3 | 10 | 63 | 10 | 42 |
| 'Tedion' | 100 | 100 | | 100 | |
| | 30 | 85 | 100 | 100 | |
| | 10 | 79 | 97 | 100 | |
| | 3 | 87 | 99 | 94 | 98 |

but no deleterious effect could be noted even after ten days.

'Tedion *V* 18' did not show any visible effect on flies, beetles, aphids and other insects when these were exposed to a dry residual film. Bees were not poisoned by contact or by ingestion of contaminated food. The oral median lethal dose for mice of 'Tedion *V* 18' exceeds considerably 5 gm./kgm., for this dosage did not cause death or any visible symptom of intoxication among the test animals. Therefore it appears to be a highly specific compound which is safe for the operator and the consumer of the treated products.

Other mites are also killed by 'Tedion *V* 18'. Field trials on fruit tree red spider (*Metatetranychus ulmi* Koch) have shown that one post-flowering treatment may keep the orchards practically free of red spider up to the autumn. Successful results have been obtained on apples, pears, plums, cucumbers, grapes, carnations, roses and other horticultural crops in the Netherlands, Belgium, Luxemburg and France.

Details of laboratory and field-trials will be published elsewhere.

## Control of Yeast Contamination by 'Mycostatin' in Cultures of the Virus of Foot-and-Mouth Disease

Cultures of the virus of foot-and-mouth disease by Frenkel's method[1], in which the epithelial tissue of the cattle tongue is used, is being widely adopted for the provision of virus for vaccine production. The tongue epithelium is grossly contaminated with bacteria and yeasts, and antibiotics must be included in the culture medium for their suppression. The bacterial contamination that we have encountered has been effectively controlled by penicillin and streptomycin; but the problem of inhibiting the growth of yeasts remained. During December 1954–March 1955, fourteen apparently distinct strains of yeasts have been isolated from virus cultures in which the tongue tissue was from cattle slaughtered in London. An attempt is being made to identify these strains using the classification of Lodder and Kreger-van Rij[2]. This has led, so far, to recognition of species from the genera *Endomycopsis*, *Saccharomyces*, *Sporobolomyces*, *Candida*, *Kloeckera*, *Trichosporon* and *Rhodotorula*.

It has now been found possible to control this yeast contamination by the addition to the culture medium of 'Mycostatin'[3], an antifungal substance from a soil actinomycete originally extracted by Hazen and Brown[4]. In *in vitro* tests, 'Mycostatin' inhibited the growth of thirteen of the above fourteen strains in a concentration of 20 units/ml., and the remaining strain was inhibited by 80 units/ml. The addition of 20 units/ml. to the virus cultures has resulted in complete control of yeast contamination. Using fourfold increases in concentration, no decrease in virus multiplication was observed until 320 units/ml. had been exceeded.

We are indebted to Messrs. E. R. Squibb and Sons for supplies of 'Mycostatin'.

## Reproduction in the Cat-fish, *Clarias mossambicus* Peters.

No precise information has been published on the breeding habits of *Clarias mossambicus*. Although previous authors who have studied this species in the field give records of ripe females[1] and breeding fish[2], definite spawning sites have apparently never been determined, nor have the eggs, embryos and larvæ been described.

During recent rains in Uganda an actual spawning site was investigated. Spawning took place in the flooded, low-lying areas adjacent to a shallow drainage stream flowing into Lake Victoria, near Jinja. This stream is separated from the lake by a narrow papyrus swamp which is succeeded on the landward side by a thin belt of the grass *Echinochloa*. When not in spate, the stream is reduced to a series of shallow, disconnected pools without direct surface-water connexion with the lake. Under flood con-

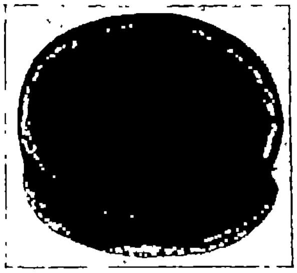

Fig. 1. Fertilized ovum of *Clarias mossambicus*; seen by transmitted light. Magnification c. × 20

ditions the stream overflows its banks, inundating the low-lying *Echinochloa* zone, which becomes a temporary and shallow swamp. Attention was drawn to the presence of adult *C. mossambicus* (normally absent from this stream) by the large number of African fishermen seen spearing these fish. A small sample of speared fish examined showed that females had either ovulated or were likely to ovulate within a short period. All male fish caught were apparently ripe.

Evidence indicating when sexually active fish first ascended the stream is both scanty and equivocal. African fishermen claimed that fish first appeared on April 11; on the other hand, subsequent collections of larvæ demonstrated the presence of young fish at least three weeks older than those known to have been spawned on April 12. More positive evidence is available regarding the time by which adults had returned to the lake. From both fishing activity and personal observation, it seems that few adults remained in the stream four days after fertilized eggs were first found. At this time the extent of the stream and swamp was greatly reduced.

Fertilized eggs were found among the accumulated plant debris lying in pools and side runnels of the main stream. Despite intensive search, very few eggs were found in the main stream or in sites from which the debris had been scoured by the flood. A surprising feature in the spatial distribution of eggs and early larvæ was their dispersion, in small groups of from five to ten individuals, over a considerable area.

The fertilized ovum is small and sub-elliptical in cross-section, having mean greatest and least diameters of 2·0 mm. and 1·5 mm. respectively. The translucent straw-yellow yolk almost fills the vitelline space. A characteristic feature is the large adhesive disk, about 0·5 mm. deep, which entirely surrounds one pole. The outer surface of this disk follows the general contour of the underlying chorion; at its centre there is a well-marked pit-like depression (Fig. 1). Sheets of a glutinous and elastic substance which are extruded from the disk firmly anchor the egg to the substrate.

Since an accurate temporal base-line is known only for laboratory-raised embryos obtained in the first instance by artificial fertilization, the developmental times given below refer to these individuals.

Within an hour of fertilization the fourth blastodermal cleavage has taken place, the blastodermal disk occupying the pole opposite the adhesive disk. After nine hours there is a well-defined embryonic shield lying equatorially. Hatching takes place between twenty-three and twenty-five hours after fertilization. For comparison, it may be noted that *Tilapia esculenta* and *T. leucosticta* raised under similar conditions hatch between five and six days after fertilization. Newly hatched *C. mossambicus* larvæ are 3·5–4·0 mm. long; the first two gill slits are open, and there is a clearly defined opercular fold. The larvæ swim actively, and are not confined to the substrate. A small, but distinct, ventral sucker is developed on the vitelline membrane. The adhesive properties of this sucker are considerably less than those of the chorionic adhesive disk.

Development after hatching is also rapid, especially during the first fifty hours. Perhaps the most outstanding morphological features of this period are the large olfactory sacs, which dominate the anterior cephalic region, and the precociously developed circum-oral barbels.

Between thirty-seven and thirty-nine hours after hatching, an extensive and well-developed vascular network is visible on the expansive branchiostegal membrane. At this stage the operculum is clearly defined, and two cartilaginous branchiostegal rays are present. Preliminary investigation leads me to interpret the branchiostegal vascular net as an extension of the hyoidean vascular arch, without its subdivision into afferent and efferent vessels. Blood flows into this network from the ventral aorta, and after circulating through the net is collected into a single vessel which joins the paired dorsal aortæ behind the eye. It is suggested that the hyoidean vascular net functions as an accessory gill. In larvæ one week old these vessels may still be traced, but thereafter increased pigmentation precludes further direct observations on living material.

The yolk sac is completely resorbed four days after hatching, at which time the larvæ have attained a length of 7–8 mm. and are clearly recognizable as young *Clarias*. The vitelline sucker ceases to be functional at about this period, and is soon lost.

Embryos raised *in vitro* were kept within the temperature-range of 23·0–24·5° C., whereas under natural conditions embryos were subject to a diurnal temperature variation as great as 6 deg. C. (22°–28°). So far as could be determined, development *in vivo* was slower than in the laboratory, there being a time lag of nearly 100 per cent during pre-hatching development, later reduced to 25 per cent by the time that the yolk had been resorbed. Oxygen tension, probably associated with the intensity and turbulence of water flow, is doubtless an important feature in controlling developmental rates. It was noticed, for example, that early development was faster in embryos raised in dishes with a strong current agitating the water than in those supplied with only a slight water flow. Larvæ resulting from artificial fertilization did not survive beyond five days after hatching.

The temporary nature of the spawning area is emphasized by the fact that six days after the discovery of early embryos, the principal spawning site was completely isolated from the main stream. Also at this time, larvæ were first found in the stream; these were at a developmental stage comparable with those still remaining in isolated areas of the swamp. A rapid fall in water-level now occurred, which resulted in many larvæ being concentrated in small isolated pools approximately a foot in diameter and six inches deep. In one such pool the midday surface temperature was 34° C., while six inches below, the temperature of the mud was 25° C. Larval fishes continued to live under these conditions for three days without any marked diminution in their numbers. Finally, on the fourth day the pools dried out completely.

Collections made in the main stream indicated a fairly constant and dense population of young fish over a period of eight days after the first appearance of larvæ in this habitat; however, with the gradual break-up of the stream into disconnected pools, the number of larvæ decreased suddenly and has remained at a low level for some weeks. If these environmental conditions are typical for this period of the 'long' rains, then it would seem probable that larval *O. mossambicus* suffer severe mortality before reaching the lake. On the other hand, rainfall in this area during March and April had been unusually light and irregular.

It has not yet been determined at what stage in the life-history young fishes find their way into the lake.

A full description of embryonic and larval development in *O. mossambicus* will be published elsewhere.

## Elementary Bodies in Bovine Malignant Catarrh

MALIGNANT catarrh in cattle is widespread, occurring in Africa, America and Europe. Henning[1] has described the clinical syndrome which invariably terminates in death. The etiological agent, although believed to be a virus, has never been described. The disease can be transmitted to cattle by needle passage of spleen/gland emulsions[2]. It has also been adapted to rabbits[3].

The rabbit-adapted strain affords an easier and more economical means of investigation, and, in view of Mettam's[4] remarks that "The virus must be fairly large and only invisible because of some natural peculiarity . . .", it was decided to make a minute examination of smears and sections obtained from various infected rabbit tissues. Using Castaneda, Macchiavello and Giemsa staining, it was observed that elementary and initial type bodies were present in most tissues, but especially spleen, gland, lung and appendix, which resemble those of the psittacosis group of viruses (Fig. 1). These bodies showed the pleomorphism, colour variation and location as described by Bedson and Bland[5].

A check was then made on smears and sections of bovine tissues already prepared, and although the virus is present it is much less numerous and more likely to be confused with cellular debris.

An attempt was also made to establish the disease in fertile hens' eggs using 0·2 c.c. of a 10 per cent spleen emulsion from an infected rabbit, but after only two passages in the yolk sac of eight-day old embryos it was unavoidably necessary to discontinue this work for some months. Smears from yolk sac and chorio-allantoic membrane revealed various forms of the virus, but elementary bodies were undetectable.

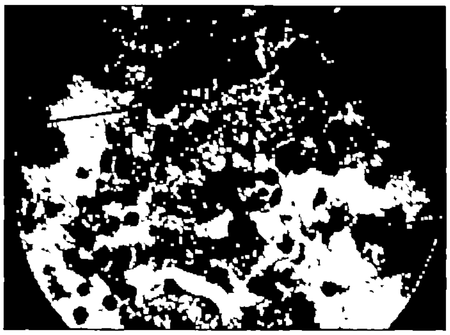

Fig. 1. Rabbit lung stained with Giemsa. Initial bodies, mainly intracellular, are marked by arrows. × 660

In view of the fact that psittacosis virus can be stored for some months by placing infected yolk sacs in deep freeze, and despite the fact that the viru of malignant catarrh will only remain viable for one to two weeks according to all previous investigators it was decided to place one yolk sac in a sterile container in the deep freeze at – 10° C. At the same time the bovine needle passages were also discontinued, but passages in rabbits were maintained. However, after four months from this time (fifty-seventh passage), the rabbits failed to react.

After eight months, when it was possible to resume the work, the frozen yolk sac was emulsified in nutrient broth to make a 10 per cent yolk sac emulsion, and 0·2 c.c. was inoculated into the yolk sac of eight-day old fertile hens' eggs. After a further two passages, 10 c.c. of a 10 per cent whole egg emulsion was inoculated into the prescapular glands of two cattle.

Four weeks later one animal reacted with symptoms associated with malignant catarrh, and this was confirmed by post-mortem findings. A 10 per cent spleen/gland emulsion from this animal was subinoculated into a further two animals by the prescapular gland route, and after three weeks one of the animals reacted, again with typical clinical and post-mortem findings associated with malignant catarrh. Using whole egg emulsion from the fourth egg-passage after storage, a further four cattle were inoculated intratracheally. Three reacted in three to four weeks, again with typical symptoms; but one of these, a young native bull, survived. Thus, a complete cycle, bovine—rabbit—fertile hens' eggs—bovine, has been completed.

Natural infections of malignant catarrh have not been recorded at Kabete.

Papers embodying the results of these studies are being prepared and will be published elsewhere.

## New Free Amino-Acids in Plant Materials

RECENT research[1] indicates the presence of 5-hydroxypipecolinic acid as well as possibly hydroxylysine, besides pipecolinic acid and baikiain in the non-protein nitrogenous fraction of plant materials.

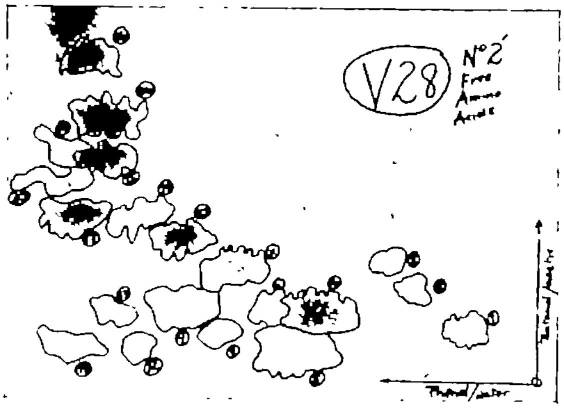

Fig. 1. Ethanolic extract of lucerne hay cut at 14 cm. First phase: phenol–water (4 : 1)/ammonia atmosphere. Second phase: *n*-Butanol/acetic acid/water (4 : 1 : 5, upper layer). Ninhydrin development: 1, Aspartic acid; 2, glutamic acid; 3, 3 . 4 - dihydroxyphenylalanine; 4, serine; 5, asparagine; 6, glycine; 7, threonine; 8, citrulline; 9, glutamine; 10, alanine; 11, β-alanine; 12, histidine; 13, unknown (? ε-aminohydroxycaproic acid or methionine sulphone); 14, valine + methionine; 15, γ-aminobutyric acid; 16, leucines, 17, proline; 18, arginine + lysine; 19, pipecolinic acid; 20, baikiain

Previously unidentified ninhydrin-reactive sub-tances have been found to occur in the hydrolysed[2a] nd unhydrolysed[2b] ethanolic extracts of lucerne hay ut in different stages of growth and in certain marine lgae[3], as well as the extract of fenugreek seeds[2a].

Fig. 1 shows a two-dimensional paper chromatogram of the ethanolic extract of lucerne hay cut at 14 cm. in height (Liběchov). Among the ninhydrin-eactive spots occurring on the chromatogram are hose corresponding to pipecolinic acid (spot 19), aikiain (spot 20) as well as citrulline (spot 8) and ossibly ε-aminohydroxycaproic acid or methionine ulphone (spot 13). The work of Koloušek indicates hat pipecolinic acid is present in mature lucerne hay Tábor) as well as citrulline[4].

An identical picture is given by the ethanolic xtract of lucerne hay cut at 12 cm. in height.

A further unknown ninhydrin-reactive substance occurs sometimes near asparagine (with the same $R_F$ n phenol–water/ammonia as glycine but just below sparagine). This may be ethanolamine phosphate r α-ε-diaminopimelic acid (Work, E., personal ommunication).

5-Hydroxypiperidine-2-carboxylic acid does not eem to occur in these hays, but an unknown inhydrin-reactive substance is found in certain arine algae[3] in the position of this amino-acid on wo-dimensional paper chromatograms (it only gives weak reaction with alloxan and isatin)[2b,3].

A brown ninhydrin colour is given by another nknown substance occurring in the hydrolysates of thanolic extracts of lucerne hay[2a].

Spot 3 is thought to be 3 : 4-dihydroxyphenyl-lanine[2b].

## Isolation of Ectotrophic Mycorrhizal Mycelia from Rhizomorphs present in Soil

In a recent communication in *Nature*, Warcup[1] described a technique devised for the isolation of fungi directly from hyphæ distributed in soil. By this method he succeeded in isolating a number of fungal species including basidiomycetes generally absent from dilution plates.

During researches on soil fungi carried out at Bedford College, mycelia known to form ectotrophic mycorrhizal associations have been isolated from soil rhizomorphs using the following method: fresh rhizomorphs picked out of the soil were washed for approximately 10 sec. in 0·1 per cent hydrochloric acid, then rinsed in sterilized water and plated on nutrient media commonly used for culturing mycorrhizal fungi. In this way *Boletus bovinus*, *B. scaber* and *Mycelium radicis nigrostrigosum* were isolated from soil brought in from the field and from experimental soil cultures grown in the laboratory.

The accompanying photograph shows a sample of rhizomorphs of *B. bovinus* used for isolation purposes. These hyphal strands, present in a certain heathland soil under investigation, exhibit a pinkish-brown colour. Their average diameter is 60–70μ. Each rhizomorph consists of a central cylinder formed by 1–3 hyphæ 4–5μ wide, enclosed within a sheath of more slender hyphæ each 2–3μ in diameter. Clamp connexions have not been observed in the hyphal filaments forming these rhizomorphs. In the particular soil mentioned above, *B. scaber* and *M. r. nigrostrigosum* were observed to develop hyphal strands structurally not dissimilar from those described for *B. bovinus*.

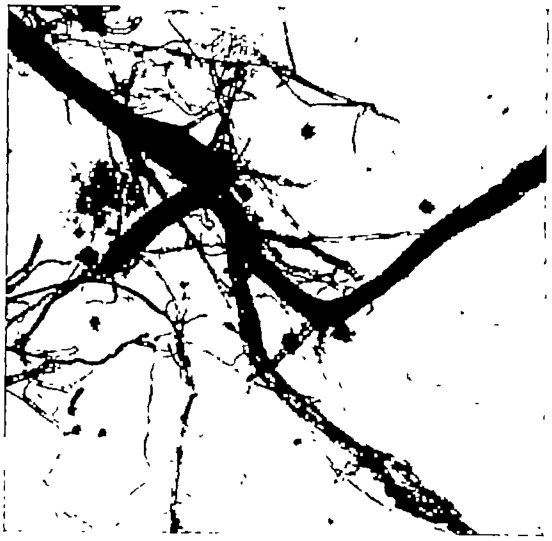

Fig. 1. Soil rhizomorphs of *Boletus bovinus* as used for the purpose of isolation. × 140

The isolation of ectotrophic mycorrhizal mycelia from soil rhizomorphs by means of surface sterilization has proved a convenient method of obtaining pure cultures of these fungi which, so far, have resisted isolation from individual hyphæ.

## FORTHCOMING EVENTS

### Monday, September 12

Institute of Metal Finishing (at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. F. Wild: "Fluoborates in Plating".

### Monday, September 12—Friday, September 16

Imperial College of Science and Technology (at the Royal Institution, Albemarle Street, London, W.1)—Third London Symposium on "Information Theory".

### Tuesday, September 13—Saturday, September 17

Society of Dyers and Colourists (at the Northern Counties Hotel, Portrush, Co. Antrim, N. Ireland)—Symposium on "Bleaching, Dyeing and Finishing To-day".

### Wednesday, September 14—Saturday, September 17

National Physical Laboratory (at Teddington)—Symposium on "Cavitation in Hydrodynamics".

### Friday, September 16

Biochemical Society (in the Department of Biological Chemistry Marischal College, Aberdeen), at 2.15 p.m.—Scientific Papers.

### Saturday, September 17

Nutrition Society, Scottish Group (in the Physiology Lecture Theatre, Marischal College, Aberdeen), at 1.40 p.m.—Symposium on "Cholesterol and Fat Metabolism in Relation to Diet and Disease".

## APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Applied Mathematics—The Registrar, The University, Nottingham (September 19).

Reader in Applied Mathematics at the Imperial College of Science and Technology, London, S.W.7—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 21).

Research Assistants (2) (with a good honours degree in physics or physical chemistry) in the Department of Mining—The Registrar, The University, Leeds 2 (September 23).

Assistant Physicist (with a good honours degree in physics and preferably with experience in electronics and nuclear physics techniques) in the Physics Department of the Sheffield National Centre for Radiotherapy—The Secretary, Sheffield Regional Hospital Board, "Broom Cross", Tree Root Walk, Sheffield 10 (September 24).

Physicist (with a first- or second-class honours degree or equivalent, and preferably with some experience of optics, heat transfer, or radiation problems) at a Ministry of Supply Research Station near Salisbury, Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.312/5A (September 24).

Lecturer in Civil Engineering—The Registrar, The University, Leeds (September 26).

Assistant Lecturer in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (September 30).

Lecturer in Organic Chemistry—The Secretary, Queen's University, Belfast (September 30).

Lecturer in the Department of Biochemistry—The Secretary of University Court, The University, Glasgow (September 30).

Librarian (with recognized qualifications in librarianship and experience in a special library, and preferably with a knowledge of botany and major foreign languages) of the Royal Botanic Garden, Edinburgh—Chief Librarian, Ministry of Works, Lambeth Bridge House, London, S.E.1 (September 30).

Senior Lecturer in Anthropology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Lecturer in Farm Management—The Secretary and Registrar, University College of North Wales, Bangor (October 1).

Lecturer or Assistant Lecturer in Biochemistry—The Registrar, The University, Sheffield (October 1).

Senior Lecturer, Lecturer or Assistant Lecturer in Inorganic Chemistry at the University College of Khartoum, Sudan—The Secretary, Inter-University Council, 1 Gordon Square, London, W.C.1 (October 1).

Chief Assistant Chemist and Bacteriologist (Associate or Fellow of the Royal Institute of Chemistry, and preferably with experience of water analysis and treatment)—The Engineer and General Manager, Sunderland and South Shields Water Company, 29 John Street, Sunderland, quoting "Chemist and Bacteriologist" (October 15).

Lecturer in Philosophy at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 15).

Lecturer (proficient in anatomy and cytology and preferably with a good knowledge of cytogenetics) in the University Department of Botany, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Johannesburg, October 15).

Senior Lecturer (with teaching experience at university level and an honours degree and a research degree in zoology) in Zoology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 31).

Agricultural Officers (with a university degree in agriculture or natural science) in the Gold Coast Local Civil Service, to advise the Director of Agriculture on current district agricultural problems, to manage District Agricultural Stations, and to implement agricultural policy in their respective districts—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.63/12/04.

Electronic Physicists and Engineers, Scientific Officer or Experimental Officer class, at Ministry of Supply Experimental Establishments near Farnborough, Hants; Malvern, Worcs; Sevenoaks, Kent; Aberporth, S. Wales; and London H.Q., for research and development on guided weapons; radio, radar and communications; and electronic devices—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.302/5A.

Hospital Physicist (with an honours degree in physics, and preferably with experience in hospital physics) in the Radiotherapy Department—The Secretary, Romford Group Hospital Management Committee, Romford.

Mechanical and Aeronautical Engineers, Aerodynamicists, Applied Mathematicians, Physicists and Physical Chemists (with a first- or second-class honours degree or equivalent qualification) at the Ministry of Supply National Gas Turbine Establishment, near Farnborough, Hants—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.661/5A.

Research Assistant (with an honours degree or equivalent qualification in electronics) in the Department of Physiology for work on auditory physiology—The Secretary, Charing Cross Hospital Medical School, 62 Chandos Place, London, W.C.2.

Scientific Officer (with a first- or second-class honours degree or equivalent in physics, mechanical or chemical engineering) at the Ministry of Supply Research and Development Establishment, Waltham Abbey, Essex, to assist in research on heat transfer phenomena at high temperatures—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.329/5A.

# REASON AND SURVIVAL IN THE MODERN WORLD

NEARLY twenty years ago, in his Conway Memorial Lecture, under the title "The Retreat from Reason", Prof. L. Hogben argued that this 'retreat' was the result of our failure to ensure that, on one hand, the training of the statesman and the man of letters gave them prevision of the technical forces which were shaping the society in which they live, whereas, on the other hand, the education of the scientist and the technician did not make them aware of the social consequences of their own activities. It was accordingly necessary to devise an education which would give us representatives capable of co-operating intelligently with technical experts in constructive social enterprise, and teach us how to choose them. Prof. Hogben then developed his argument for encouraging a wider knowledge of science as a means to action, and outlined a proposal for an institute of social inquiries, and in doing so made numerous comments—for example, that the most expensive products of modern social organization are uneducated men—the truth of which has been amply attested in recent months.

Prof. Hogben's lecture is recalled to mind by the appearance of a special number of *The Political Quarterly* in which, under the general title "The Revolt against Reason", a series of nine articles examines from different angles the evidence for the alleged great reversal during the past forty years of the nineteenth-century climate and movement of ideas, and whether in fact there has been a great revolt against reason, science, and the ideas and ideals of the French Revolution. While, however, the articles indicate that there has indeed been a revolution in scientific thinking and a profound change in the whole climate of our thought, they reveal no convincing evidence of the cataclysmic failure of, or revolt against, reason. The result has been rather a deep confusion, a loss of direction in the political and social mind, both of the expert and specialist and of the ordinary man. The symposium suggests that if we eventually digest the new ideas and adapt ourselves to the new conditions, then we must do it with the aid of reason; but there the affinity with Prof. Hogben's lecture ends. A challenge to thought there may be, but scarcely one to action.

Of the nine articles, those in which Dr. J. Bronowski deals with science, Mr. R. Wollheim with philosophy, and Mr. Noel Annan with the general intellectual revulsion to the right may be of most interest to the man of science. Those of Prof. D. Emmett on religion, of Mr. D. G. MacRae on social science, of Mr. L. Woolf on history, and of Mr. H. R. C. Greaves and Mr. W. Pickles on political thought in Britain and in France, are required, however, to complete the picture of the existing climate of belief, while finally, Mr. R. Bryden analyses the attitude of the younger generation in the universities.

The real situation is well shown by Dr. Bronowski, who proves as stout a champion of reason as any product of the nineteenth century. Discoveries connected with the atom, quantum theory and relativity have made some of the assumptions or conclusions of Newtonian science untenable. The new thought in science is based none the less on new facts, and its predictions have a formidable accuracy, as well as a calculated uncertainty within which we work confidently and methodically. We recognize now that the world is not made in a pattern which can be described by specifying its separate points; but this lends no support to the argument that we can safely abandon the use of reason and substitute the instrument of faith. Nuclear science has released neither scientist nor layman from the duty of using his reason; on the contrary, it has made the scrupulous use of reason even more essential for survival. Similar thoughts were evidently in the mind of Sir Robert Robinson when he spoke in his presidential address to the British Association meeting at Bristol of the need for the freeing of information in this field.

Mr. Wollheim's review of modern philosophy and unreason leads to a like conclusion: that to stand on the side of reason is a matter not of arriving at certain conclusions but of using certain methods. Prof. Emmett, surveying much the same field but more particularly in relation to discussions on religious questions, can find no unequivocal evidence of a revolt against reason but insists rather that there is a problem of communication to be solved. She suggests that there may be signs that a more widespread awareness of problems raised by our uses of language, questions from which not even an exposition of theology can be immune, may lead to a greater readiness on all sides to try to see what it means to be rational in questions which touch ultimate attitudes and beliefs.

It might have been expected that Mr. MacRae, tracing the influence of irrationality and obscuration in the social sciences, would come nearer to Prof. Hogben in his conclusions. While, however, he shows as clearly as Prof. Hogben the obstacles which hinder the development of the social sciences to-day, and agrees with him that only growing rational understanding can give to men control of their natures and of their societies, Mr. MacRae is not concerned with practical problems. He finds no evidence of a genuine retreat from reason and observes that the decision to follow reason is always a moral choice, but in the social sciences in the mid-twentieth century, the task of following reason is a technical one.

Nor do Mr. Annan's or Mr. Greaves's articles warrant pessimism. Mr. Annan's examination of the factors responsible for the intellectual movement to the right leads him to suggest that politically we live again in the age of Bagehot, and that what is needed is a new series of cohesive arguments which will again persuade people that our institutions need changing, not modifying, and that reason is a tool for discovering what changes are necessary and not a means of justifying the present and explaining why it can never improve. Mr. Greaves concedes that the belief in an inevitable progress along predetermined channels of rational, humanitarian, democratic advance has gone, but not that there is real evidence of any failure to relate the stability of institutions in a precarious world to the old principles of rational humanitarianism. There is certainly wider agreement now than at the beginning of the century on basic principles and on objectives, and while that agreement may be less optimistic as to the essential reasonableness of human nature and the inevitability of progress, it is not anti-rational or anti-democratic.

Mr. Bryden's survey of the attitude of the younger generation in the universities ends on a like note. The apparent revolt against rationalism there, in his opinion, amounts not to rejection of the tradition of Bentham and Mill, but to a re-examination of the other tradition, from Coleridge to Green, which in retrospect seems to amount to the philosophy of the other great force which complemented nineteenth-century liberalism. Rationalism, he insists, may have entered the wilderness, but its younger disciples in the universities show themselves determined not to let it die out. Then in two sentences he brings the symposium closer to practical issues than his fellow-contributors seem to do. "If the tradition of rationalistic radicalism does not stir the universities as it once did, surely this is because the universities have lost their sense of community with the rest of the nation." There may have been no deliberate abdication of leadership, but it is scarcely possible for the scientist to be disliked and distrusted by the public in the way that Dr. Bronowski remarks unless the universities have failed to rise to their responsibilities of intellectual leadership. Quantitatively, their post-war expansion should have greatly enhanced their influence on public opinion in Britain, and a failure to seize the wider opportunities may well account in part for difficulties in shaping educational policy to public needs, whether we look, for example, at the expansion of technical and technological education or at the continuing shortage of science teachers. Moreover, the lacuna to which Mr. Bryden directs attention has its dangers for the universities themselves, as Sir Hector Hetherington made abundantly plain in his Anderson Memorial Lecture on "The British University System" delivered in Aberdeen last year*. Academic autonomy depends ultimately on public understanding of what the universities are doing and how best their work is done.

For the second practical issue: if the twentieth century has made anything clear, it is that nations are all too concrete; it may be irrational to adore societies; it seems still more irrational to ignore their existence and their strength. Set those words in the context of some of the platitudes with which distinguished contributors to "The Bomb: Challenge and Answer"† were content to leave the problems with which nuclear energy confronts mankind, and the imperative need for keen, rational thinking which now confronts mankind is plain. Here, at least, and in Dr. Bronowski's essay, a challenge is thrown down in quiet confidence that reason still offers a guide, and the only sure guide, to the right answer to problems of to-day.

The call to action is given less insistently than it was by Prof. Hogben, but it is there none the less. We may be less confident where reason will take us, and we recognize that there are fields of human experience of which science can tell us little or nothing. But that hard thinking and readiness to follow the argument and pursue the inquiry wherever they lead are the essential conditions for solutions to the problems of human survival and existence are as true to-day as ever. For an effective policy, however, we need, as Sir Richard Livingstone reminds us, clear and firm beliefs. Without them we may not only fail to draw the moral lessons we might from history, but also our thinking may lead us not to action but into a miasma of doubt and frustration. Mr. Woolf's contribution to the symposium, at least, displays that danger; but for the rest the symposium has little of the 'ivory tower' about it. Its challenge to hard thought contains more than a hint that such thinking needs to crystallize in action, and indicates at least some of the enterprises of great moment to which our thought should lead.

# SCIENCE AND PETROLEUM

## The Science of Petroleum

A Comprehensive Treatise of the Principles and Practice of the Production, Refining, Transport and Distribution of Mineral Oil. Vol. 5, Part 3: Refinery Products. Edited by Dr. B. T. Brooks and Dr. A. E. Dunstan. Pp. ix+398+23 plates. (London: Oxford University Press, 1955.) 126s. net.

THIS is the most recent addition to the four original volumes published in 1937 and is the fourth supplement to be issued. As it may represent a stage in the successive renewals of an outstanding record of the science and technology of mineral oil, opportunity is taken of referring to the work as a whole. The conception of "The Science of Petroleum" was heroic. It was the thought of A. E. Dunstan more than any other, who sought a means of overcoming the ever-increasing pressure of advancing knowledge required by the man of science and the technologist in an industry of the widest interests, without having immediate recourse to the very many original publications in journals and monographs spread throughout the world's literature. It was not to take the form of a series of abstracts or summaries, nor to be a collection of treatises; but to become an ever-living progression of articles concerned with aspects, achievements and trends written by contemporaries of acknowledged authority. The attempt was successful. "The Science of Petroleum" will continue to live and flourish indefinitely.

The first half of the contents of "Refinery Products" is mainly directed to the characterization of commercial fractions of crude oil as separated at the 'refinery', and ranging from aviation and motor asolines through middle distillates to white oils and raxes. The remainder is mostly concerned with the laboration of test methods. There is therefore little rocess and manufacturing material additional to hat appearing in Vol. 5, Part 2, and what there is eals with relatively minor products and their pplications. It had been hoped that in suitable uise room could have been found for description of he more recent developments in directive catalytic ydroforming and desulphurizing, which are having truly profound influence on refinery practice and roducts. But at the pace new volumes are being repared for the series, one may not have to wait verlong for such disquisitions.

---

* The British University System 1914–1954. By Sir Hector Hetherington. (P. J. Anderson Memorial Lecture, 1954. Aberdeen University Studies—No. 33.) Pp. 13. (Edinburgh and London: Oliver and Boyd, Ltd., 1955.) 1s.

† The Bomb: Challenge and Answer. By Prof. Alexander Haddow, Bertrand Russell, Lord Beveridge and Henry Usborne. Edited by Gilbert McAllister. Pp. 160. (London: B. T. Batsford, Ltd., 1955.) 25s. net.

There are many noteworthy essays in the volume, nd one is forced into generalities of appreciation; ut it is perhaps in the matter of testing that the igh standard of modern petroleum technology is best ortrayed. Both for length and substance (close on ne hundred pages) the contribution of W. G. Lovell n the knocking characteristics of hydrocarbons is a ood example. Here is a subject based on engine esting, many of the data of which are those resulting rom the American Petroleum Institute Research Project 45. It is a subject which will with difficulty each finality because of the friendly competition etween chemist and automobile engineer, each in urn taking the lead in providing or demanding motor uels of higher octane rating. The procedure for ngine-testing appraisement of light fuels has already een standardized between the American Society for Testing Materials and the Institute of Petroleum. The two articles on engine testing of lubricating oils re a reminder of the impetus given also to this important subject by the Co-ordinating Research Council of New York and willingly followed up and developed by British engine manufacturers and oil ompanies.

The last big section of the volume is impressive in its indication of the extent to which modern advances in infra-red spectroscopy, Raman spectroscopy and the use of the mass spectrometer are being applied in hydrocarbon studies and analysis. Imposing, too, are such articles as those of D. Tabor and F. P. Bowden on boundary lubrication, and of J. M. Robertson on X-ray examination of hydrocarbons. But modestly among these more learned contributions, yet of great importance to the subject of international standardization, is one of barely five pages by H. Hyams on volume and specific-gravity corrections for petroleum oils. The chief reference in this article is to the work carried out by the Institute of Petroleum and the American Society for Testing Materials in the preparation, and now the joint publication, of "Tables for Petroleum Measurement". This is the first, and by no means likely to be the last, instance of fully collaborative effort between the petroleum technologists of Great Britain and the United States.

The three impressive volumes which have recently been produced are not merely evidence of this spirit, but fully justify Hyams's claim that they will eliminate buying and selling differences and difficulties throughout the great areas primarily concerned, and will assist in the establishment of world-wide uniformity: this will be a great achievement in the commercial domain of the world's outstanding commodity. The book is a pleasure both to scan and to skim. The Oxford University Press continues its very high standard of production for this great work.

S. J. M. Auld

# CHEMISTRY OF NAPHTHALENES AND STEROLS

Elsevier's Encyclopædia of Organic Chemistry
Edited by F. Radt. Series 3: Carboisocyclic Condensed Compounds. Volume 12*B*: Naphthalene. (*A*) Compounds containing One Naphthalene Nucleus. Oxo-Derivatives of the Naphthoic Acids; Naphthalenepolycarboxylic Acids. Pp. xliii+4561–4840+34; £10 15*s*. Vol. 14: Supplement. Nor-Steroids. Steroids: Hydrocarbons, Halogen, Nitrogen, and Unsubstituted Monohydroxyl Compounds. Edited by A. Georg, with the assistance of M. Georg-Plant. Pp. xxxix+1347*s*–1868*s*; £18.
(Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd., 1954.)

THE first of these two books is the eighth part of a series and marks the completion of a further stage in the cataloguing of naphthalene derivatives. It is stated that the literature has been consulted up to and including 1944, and the literature concerning the structure of compounds up to the beginning of 1954. The field covered includes derivatives of the naphthoic acids containing carbonyl groups, naphthoic acids containing other carboxyl groups in a side-chain, with their homologues and derivatives (with halogen, nitrogen, hydroxy and carbonyl substituents). Naphthalenepolycarboxylic acids are also covered. In this latter group naphthalic acid is perhaps the most important. As in other parts, corresponding hydronaphthalene derivatives are also treated. Descriptions are given, for example, of formylnaphthoic and benzoylnaphthoic acids and their homologues, tetralone- and decalone-carboxylic acids, and diketo-hydronaphthoic acids. In the diterpene series, a full account is given of the chemistry of agathic acid, the reactions of which are summarized in a typically informative reaction scheme covering two pages. No system of classification is perfect, and it is perhaps a little unfortunate to find such a compound as neolithobilianic acid dealt with in this part, rather than in the volume dealing with bile acids and their derivatives. The list of periodicals occupies eighteen pages, and inevitably covers much the same ground as similar lists in other parts.

The high standard of production with which users of the "Encyclopædia" are familiar is well maintained, with excellent printing, freedom from error and beautifully set formulæ. When Vol. 12*B* is complete, it will be regarded for many years to come as the unique work of reference on naphthalene chemistry.

Vol. 14 of the "Encyclopædia", dealing with carbocyclic compounds containing more than three rings, was the first volume to be published, and it covered the literature up to 1936. It contained 711 pages, 276 pages of which were devoted to the steroid group. In the second of the two books now under review, the range of compounds dealt with in 521 pages of text and 44 pages of index corresponds to 80 pages of the original Vol. 14. This is some measure of the extent of the interest shown in the steroid group in a single decade; for the present work covers the literature up to 1946, with references to the literature concerning the structure of compounds up to 1954.

The book is concerned essentially with the sterols and related hydrocarbons, and derivatives containing halogen, nitrogen and monohydroxy substituents. It seems destined to become *par excellence* the standard work of reference on sterols. A description of cholesterol and its simple derivatives occupies some 120 pages. These include accounts of physical properties, occurrence and formation, reactions and physiology, with descriptions of the addition compounds of cholesterol, its esters and its ethers. The steroid hormones, the bile acids, and the other main groups of steroids are reserved for future parts of the supplementary volume. Brief accounts of sterols of unknown structure may be expected to stimulate further research.

There is a description of the currently used steroid nomenclature, which has been adopted in the text, and the formulæ show configurations so far as these are known. There are fifteen tables summarizing the properties of closely related sets of compounds, the index gives a complete list of naturally occurring compounds considered in the text, and there is a separate formula index. This book is particularly rich in editorial footnotes which correct errors in original papers, direct attention to uncertainties and ambiguities, and in many cases make valuable suggestions as to structures of compounds. One very minor error has been detected in the text—the name "conessine" is mis-spelt on p. 1392*s*. It is no longer true, as stated on p. 1382*s*, that 1 : 2-*cyclo*pentadienophenanthrene has not yet been prepared, and this may have some bearing on the comments on pp. 1389*s* and 1811*s* about the 3′-methyl derivative.

Reaction schemes, which are a characteristic feature of the "Encyclopædia", figure to some extent in the present work, examples being schemes showing the relationships of some of the cholestadienes (p. 1419*s*) and the oxidative degradation of the side-chain and ring *D* of cholesterol (p. 1583*s*). The biosynthesis of cholesterol is briefly discussed; but there is no mention of the use of precursors containing carbon isotopes. In spite of the excellent monographs on steroids which are available, this is a work which no one concerned with the chemistry of sterols can afford to be without.

J. W. Cook

## TEXTILE PROGRESS

### Review of Textile Progress

Vol. 4, 1952; pp. 560; 35*s*. Vol. 5, 1953; pp. 588; 35*s*.
(Manchester: Textile Institute; Bradford: Society of Dyers and Colourists, 1953 and 1954.)

TEXTILE scientists and technologists have come to look forward to this annual "Review of Textile Progress", which usually appears towards the end of the year following that to which the account relates. Vols. 4 (1952) and 5 (1953) follow the same format as previous volumes, and the size of the book, which increased up to Vol. 3, has now become stabilized. The subjects covered include the physics and chemistry of fibrous materials; fibre production; conversion of fibres into finished yarns; fabric production; colouring matters; colouring of textiles; finishing of textile fabrics; analysis, testing, grading and defects; laundering and dry cleaning; building and engineering; and industrial applications of textiles.

Some thirty authors contribute the twenty-six subsections and, resulting from the policy of the joint committee, the authorship has changed considerably so that in Vol. 5 only seven of the sub-sections have the same authors as in Vol. 3 and only three authors of Vol. 1 remain as contributors to Vol. 5. However, the high standard set by Vol. 1 has been maintained. In Vol. 4 the physics and physical testing of fibrous materials was brought under one authorship to avoid overlapping, and in Vol. 5 physical testing has been transferred to its rightful place under the general heading of analysis, testing, grading and defects. Unfortunately, some unnecessary repetition has occurred; for example, references 24, 25, 44, 45, 48 in the section on physical testing duplicate references 72, 73, 77, 76, 90 in the section on physics.

In the period under review there has been a rapid expansion in the production of synthetic fibres, and it is not surprising to find a large number of papers concerned with the difficult problem of their dyeing and with applications in which their characteristic properties can be used with advantage. It should be noted that many of the so-called new fibres being produced are basic types with new trade names. Numerous patents covering fibre-forming polymers have been filed, but fibres from them will not be produced commercially unless they have really outstanding properties. The natural fibres have not been neglected. Thus, the cotton fibre has received much attention, and the resulting modifications such as cyano-ethylated cotton, together with the growth of resin treatment and embossed finishes, promise to open up new applications. Many theoretical papers with a direct bearing on the spinning and preparation processes have appeared and will influence the design of machines to give improved quality and higher productivity per operator. The dyeing of fibres appears to be passing through a period of consolidation of the new ideas published during the past five years. In printing, interesting papers on engraving have overshadowed those on mechanical invention.

There are some three thousand references in each volume to scientific and technical publications and to British and American patents; but this does not mean that the "Reviews" are simply catalogues. The accounts are essentially readable, so that one can start anywhere and become so engrossed that the end of a section is reached all too soon. Extensive author and subject indexes enable the reader to find something he has read about and may wish to read again; they also help when using the "Reviews" as source books of information. All who have taken part in producing these volumes are to be congratulated.

## THE STORY OF THE VITAMINS

### Vitamins in Theory and Practice

By Dr. Leslie J. Harris. Fourth edition. Pp. xxii + 366. (Cambridge: At the University Press, 1955.) 35*s*. net.

AFTER three editions of this book between 1935 and 1938, we have had to wait seventeen years for the fourth edition. It can be said at once that Dr. L. J. Harris has again produced by far the most readable, indeed fascinating, account of the vitamins which has yet appeared.

In simple language and in the clearest style, Dr. Harris tells the story of how the existence of the vitamins was discovered and how each was recognized and defined. The story is enthralling; so often one has read the same facts and been left quite unmoved by a cold recitation of dates and data—perhaps because we are too much concerned about the very latest developments and forget how exciting the earlier story is. Especially we overlook the brilliant work of some of the earlier investigators and how much we can still learn from their approach and their methods. Dr. Harris evokes the same interest in the description of each vitamin—where it occurs, the effects of deficiency in animals and in man, its chemistry and mode of action. By ingenious tables and figures, of which there are more than a hundred of each, essential points are frequently summarized and clarified throughout the book, so that, in spite of its easy readability, the student using it as a text-book will find it admirably suited to his needs. The final section of the book has useful and important things to say on dietetics—the application of nutritional science to the feeding of man. Here are discussed questions of food choice and instinct, the effect of war and rationing, ideal diets and common food faults.

While there is no doubt that this is by far the best book, at a fairly elementary level, which has been produced on the subject of the vitamins, one must reluctantly say that even so it is not the ideal book. One would have liked to see a rather more ruthless pruning of some of the older material and its substitution by newer information. The book abounds in examples of how Dr. Harris, better than so many other writers, could have achieved this. While most of us still remember that the Dutch East Indies are now Indonesia, how many remember which country was once Bosnia ? Is it not now accepted that "a scaly follicular eruption" of the skin is by no means a "fairly clear symptom of vitamin A deficiency" ? Anti-vitamin K has not merely a *possible* use in medicine—it is, in fact, used extensively. It is misleading to say that riboflavin deficiency is "uncommon in most regions of the globe". It is a pity, too, that reference has not been made to the Bataan experiment, where beriberi has been almost completely eradicated by the enrichment of rice, nor to the claims—mostly unfounded, it is true—of the therapeutic uses of vitamin E. Apparatus described for measuring dark adaptation has long been recognized as unsatisfactory.

However, let it be said once again that these small criticisms still leave this book easily the best to recommend, not only for students of nutrition but also for anyone who is interested in a subject about which there is so much misinformation. It is well produced, a pleasure to handle and a joy to read. JOHN YUDKIN

# LIBERTY IN THE MODERN WORLD

The Spirit of Liberty

Papers and Addresses of Learned Hand. Collected, and with an Introduction and Notes, by Irving Dilliard. Pp. xxx+285. (London: Hamish Hamilton, Ltd., 1954.) 21s. net.

THE papers and addresses collected in this book range for the most part over fields with which the man of science is concerned rather as citizen than as scientist. Even here, they could help to correct the immaturity and lack of education, to the dangers of which Conway Zirkle directed attention in a forceful address last December to the American Association for the Advancement of Science. The book takes its title from the brief address which Judge Learned Hand gave in May 1944, and the main interest of the book to the scientist lies in the interpretation of liberty and its significance in the world to-day, given by a cultured legal mind. In addresses on sources of tolerance, on liberty, on the contribution of an independent judiciary and on the debt of the world to Greece, and in the plea for the open mind and free discussion which he made as recently as October 1952, there is clear appreciation of the conditions of scientific advance or any other form of intellectual activity, of the responsibilities which the creative worker must recognize and penetrating analysis of what is involved in living together in an ordered society. Here are displayed no ready-made solutions but the ripe wisdom of a cultured mind, rich in inspiration, and confident of its exposure of humbug and pretence.

"Liberty," the author writes, "is an essence so volatile that it will escape any vial however corked. It rests in the hearts of men, in the belief that knowledge is hard to get, that man must break through again and again the thin crust on which he walks, that the certainties of to-day may become the superstitions of to-morrow; that we have no warrant of assurance save by everlasting readiness to test and test again." Elsewhere in the book he writes of the function of the scholar in a democratic State and the influence of his detachment in assuaging the faction which, admitting no mediation and demanding the extinction of all opposition, would convert the State into an autocracy "except in so far as the state is made up of those, to some degree practised in the habit of suspended judgment, and possessing a spirit capable of disinterested scrutiny". Nor does he incite the scholar or scientist to rash political action. "You cannot raise the standard against oppression, or leap into the breach to relieve injustice, and still keep an open mind to every disconcerting fact, or an open mind to the cold voice of doubt." The scholar must be content to be himself, confident that, if faithful in that, his light will shine, steady and far. Judge Hand believes in the spirit of moderation and toleration, that the scholar, whether scientist or other, brings his contribution by pursuing his inquiry where it leads him, by just 'monkeying around', by continually thinking out afresh the concepts of 'liberty' and 'independence' and the like in the context of to-day, and refusing to accept false values in their place, by maintaining wide horizons and a suspended judgment in the times of stress when men are most prone to reject them.

Supremely the book testifies to the truth of Judge Hand's contention that there is no substitute for an open mind enriched by reading and the arts, and that the scientific worker who would influence the thought and action of his time must have some acquaintance, the wider the better, with what others have thought and felt in circumstances as near as possible to those of the groups in question. Here is the fundamental reason why an education which includes the humanities is essential to correct the political immaturity of the scientist. "Just as in science we cannot advance except as we take over what we inherit, so in statecraft, no generation can safely start at scratch. . . . The imagination can be purged and the judgment ripened only by an awareness of the slow, hesitant, wayward course of human life, its failures, its successes, but its indomitable will to endure." The plea for the open mind and free discussion in which these words occur is much more than championship of dissent and a direct rebuke to the excesses of McCarthyism and secrecy and security procedures: it is an outstanding statement of the case for general education as the basis of a free society. R. BRIGHTMAN

## Atomphysik

Von Dr. Karl Bechert und Dr. Christian Gerthsen. Band 1: Allgemeine Grundlagen, Teil 1. Von Dr. Gerthsen. (Sammlung Göschen Band 1009.) Pp. 124. 2.40 D. marks. Band 2: Allgemeine Grundlagen, Teil 2. Von Dr. Christian Gerthsen. (Sammlung Göschen Band 1033.) Pp. 112. 2.40 D. marks. (Berlin: Walter de Gruyter and Co., 1955.)

THE "Sammlung Göschen" used, in the past, to provide the intelligent amateur, the teacher and the young student with short tracts on general or restricted fields of science, technology, history and philosophy and language, etc., attractively written, well printed and generally comprehensive. Since they were cheap, they allowed one to build up a valuable library which contained a great deal of information without the expenditure of a lot of money.

The "Sammlung Göschen" continues to be issued by Walter de Gruyter and Co. in succession to G. J. Goschen'sche Verlagshandlung. The two volumes under review, each of about a hundred and twenty pages, form Part 1 and Part 2 of a four-volume account of atomic physics. It is noteworthy that the joint authors, Karl Bechert and Christian Gerthsen, are both full professors at universities. The text sets out with great clarity the basic experimental facts upon which the large structure of present-day atomic physics is based, with little theory attached to it and not many formulæ. Both volumes are written with great lucidity, and the skill with which the different aspects are explained shows that the authors have considerable teaching practice. The figures and the reproduction of photographs are remarkably good for a volume of this small size (4 in. × 6 in.). I am sure these little booklets will contribute considerably to stimulating the interest of the younger generation in the physical sciences, and in view of their cheapness may well have some influence on the supply of young physicists.

In the past, Göschen used to offer its volumes cloth bound. It is regrettable that the present issue looks rather fragile and would, presumably, soon come to pieces.

E. Bretscher

## Copper

The Science and Technology of the Metal, Its Alloys and Compounds. Prepared under the Editorial Supervision of Allison Butts. (American Chemical Society Monograph Series—No. 122.) Pp. xii+936. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1954.) 160*s.* net.

TO anyone interested in copper the value of this book is inestimable. It seems to cover every aspect of production, technology and physical and chemical properties, as well as the diverse applications of the metal and its compounds. The foregoing simply does not do justice to the extent of the subject-matter, consisting as it does of forty-six chapters each on a separate topic. However, to mention a few less obvious topics—namely, isotopes of copper, its analytical chemistry, metallography of copper and its alloys, application in organic chemistry and agriculture, and biological considerations—perhaps will help to indicate better the tremendous scope of this book.

The fifty-three specialist contributors are mainly from American organizations, although there is some British and Canadian representation. Considerable latitude has been allowed to the writers in the presentation of their subjects, and the results are distinctly agreeable with respect to balance and style. The subject-matter is thoroughly up to date and is well illustrated. The printing and the paper are pleasing. The editor and publishers are to be congratulated on the production of a first-class reference book.

A. R. Bailey

## Michael Tswett's First Paper on Chromatography

By Gerhard Hesse and Herbert Weil. Pp. 35+2 plates. (Eschwege: M. Woelm, 1954.) n.p.

THE booklet is published in English and contains Tswett's preliminary communication entitled "On a New Category of Adsorption Phenomena and their Application to Biochemical Analysis", which was read in 1903 to the Warsaw Society of Natural Sciences. Although not as well known as his famous paper of 1906 on chromatographic adsorption analysis, it is clearly the forerunner of that paper. In the 1903 communication, Tswett systematically tested more than a hundred substances as adsorbents for leaf pigments and described how stepwise removal of the components from solution could be achieved by adding small quantities at a time of certain adsorbents. He also described separations of pigments on simple column-chromatograms and was able by similar means to separate the colourless substance, lecithin, from impurities, by elution through an inulin column. One is struck by the elegance of Tswett's work and how, from a few simple observations and understanding of the principles involved, he devised a technique which was destined to have such a profound influence. Following the paper, there is a section consisting of editorial notes on the paper and finally a biographical section which includes some interesting, recently discovered details of Tswett's life.

R. Consden

## A Handbook of the Palace of Minos at Knossos, with its Dependencies

By J. D. S. Pendlebury. Pp. 76+14 plates. (London: Max Parrish and Co., Ltd., 1954.) 12*s.* 6*d.* net.

JOHN PENDLEBURY was one of the more brilliant younger Ægean archæologists between the two World Wars. He was the curator at Knossos during 1929–34. In 1939 he published a major work, "The Archæology of Crete", which is a model for a book of its kind. He also did a considerable amount of work in Egypt at Tell El-Amarna. In Crete in 1941 he was wounded, captured and then shot by the Germans.

The ruins at Knossos are very extensive and complicated; they are also frequently visited both by serious students of Near Eastern archæology and by tourists. Many years ago Pendlebury set himself the task of producing a guide to the ruins which would at the same time be scientific, intelligible and readable. This handbook has long been out of print and has now been re-issued in a new edition with an introduction by the late Sir John Myres and Sir John Forsdyke. Very little previous knowledge is assumed, and the reader at once realizes the sequence of happenings at Knossos during the nine periods into which the story of prehistoric Crete is divided. There follows an itinerary through the buildings, both of the main palace and of the dependencies outside. There are a number of excellent illustrations.

The new handbook, like its forerunner, meets a real need and will be welcomed by serious students and intelligent tourists alike.

M. C. B.

# UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

## NEW SCIENCE BUILDINGS

By Prof. P. W. RICHARDS

THE new building for the Botany and Forestry Departments and the extensions to the Departments of Chemistry, Physics and Zoology of the University College of North Wales, Bangor, were opened on May 20 by Sir Keith Murray, chairman of the University Grants Committee. At the ceremony in the Powis Hall before the formal opening, many representatives of universities and other guests were present, including several representatives of the French Forest Service, which has on a number of occasions hospitably entertained forestry students from Bangor during their annual tour of French forests. One of these representatives, Prof. P. Silvy-Leligois, of Nancy, brought with him a message of good wishes from the École Nationale des Eaux et Forêts.

From the foundation of the University College of North Wales until 1926 the scientific departments were housed near the harbour. The old building, which is now demolished, was opened by Lord Kelvin (then Sir William Thomson) in 1885. The original intention had been to build more spacious accommodation by extending the College's main building in Upper Bangor (finished in 1910); but after the First World War it was decided that a major part of the North Wales Heroes Memorial Fund should be used for providing new science buildings on a site in Deiniol Road. These buildings were completed in 1926 and opened by Sir J. J. Thomson.

Until the Second World War, the number of students in the College did not exceed five hundred, less than half of whom were studying scientific subjects, and the Memorial Buildings, as they were called, proved adequate for their purpose. After the War, the size of the College more than doubled, and it became evident that the number of undergraduate scientists, let alone staff and research workers, was likely to remain permanently far larger than the Memorial Buildings could accommodate. It was thus the need for larger teaching laboratories, as well as for better research facilities, which led the College, with the generous support of the University Grants Committee, to embark on an ambitious building programme, involving the complete rehousing of the Botany and Forestry Departments and increased accommodation for the other science departments. As an essential first step, the College bought in 1947 the Tanrallt site adjoining the Memorial Buildings. It is here that the physics extension and the largest of the new buildings, that for botany and forestry, have been built.

All the new science buildings at Bangor have been designed by Sir Percy Thomas and Son, of Cardiff, and they have been built mainly by Messrs. W. T. Nicholls of Gloucester.

The first of the new buildings to be finished was the new chemistry building, which has been in use since 1950. It extends but does not replace the older building (the Orton Laboratories) and is on a closely adjacent site. In honour of Sir James Dobbie (1884–1903), the first professor of chemistry at the College, it has been named the Dobbie Laboratories. Owing to limitations of space, it has had to be built on a steeply sloping and confined site; to fit into this, it has been built in a single story in part over a semi-basement. It provides two teaching laboratories (with overhead services of gas and water) for eighty and sixty-four undergraduate students respectively, as well as a research laboratory for twelve postgraduate students, a departmental library and reading room, together with auxiliary rooms, including a general operations laboratory, an instrument room, a cold room, a room for chromatography, balance rooms and stores. There is also a lecture room seating 220, the largest in the science departments of the College.

The Department of Zoology, like the other science departments, had long outgrown its accommodation. The old Biology Block, previously shared by the Botany and Zoology Departments, has been adapted and completely refitted to provide for the teaching needs of the Department of Zoology and now includes two lecture rooms, a large laboratory for sixty students and another for thirty students, in addition to laboratories for honours degree work, rooms for staff, a workshop, photographic and instrument rooms, service rooms and three small research rooms. It continues to house the extensive museum collections in the fine room originally built for them. This block, however, could not provide enough room for the research work of the Department; consequently, a three-story building with 5,870 sq. ft. of floor space has been built on an adjoining site. On the ground floor the chief feature is two constant-temperature rooms to work from 0° to 40° C. The first floor contains a suite of laboratories, including an autoclave room and experimental theatre, a radioactive isotope room and research laboratories for the Agricultural Research Council Unit of Embryology which is housed in the Department. The second floor includes, in addition to research rooms of various sizes, an instrument room and a cool room fitted for the maintenance of cultures of marine or freshwater aquatic animals. The whole new building can accommodate fifteen research workers.

Accessible to, but separate from, this building, an animal house for small animals had been built with a floor space of 3,000 sq. ft. This is of light construction and is specially designed to exclude rodents and insect pests so far as possible. The details of its design have been published elsewhere*.

The Physics Department has been responsible, in recent years, for teaching some 150 undergraduate students and, like the Chemistry and Zoology Departments, it now uses for its teaching and research a newly constructed block together with a part of the old Memorial Buildings. The former is incomplete and allows for expansion to at least double its present size. It is of red brick, rectangular in plan, with two floors and a flat roof. The upper floor provides teaching laboratories for at least seventy students and includes, in addition to a large general laboratory, a room for experiments in optics

and two others for acoustics. More accommodation for research is provided on the ground floor, which is now used for work on nuclear magnetic resonance. Also on the ground floor are the pleasant departmental library and the staff common room.

The botany–forestry building is the largest, as well as the most ambitious in design, of the new buildings at Bangor (Figs. 1 and 2). Since the main frontage of the building stands only a few feet back from the main London–Holyhead road, a dominant consideration in its design was to exclude street noise. Because of this, on the south side of the building facing the road there are few windows and none of large size, except that lighting the main staircase; for the same reason, a large part of this side is occupied by corridors and hall spaces. At first sight, the distribution of windows might give the impression that the interior is poorly lit; but in fact all parts of the building have excellent lighting, particularly the top floor, which houses all the teaching laboratories of the Botany Department; this has a generous provision of roof lights as well as large windows on the north, east and west. The lecture rooms situated in the north-east corner of the building have no windows at all on the wall facing the main road, but are adequately lit as well as almost completely insulated from outside noise. The architect has thus successfully solved the problem of providing at the same time good natural illumination and freedom from noise on a not very easy site.

This is a red brick building on three floors. It has also a semi-basement which allows advantage to be taken of the differing levels of the front and back of the site. In addition, the flat roof is to be provided with two greenhouses, serving as additional laboratories for the physiological work of the Botany Department. Other greenhouses for departmental use are on an adjoining site. About a third of the floor space is allotted to the Forestry Department, the remainder to the Botany Department, which is responsible for training some 150 students, the majority eventually graduating in forestry, agriculture, or one of the pure sciences.

The most striking decorative feature of the building is the large entrance hall panelled with a great variety of ornamental hardwoods.

The Forestry Department, besides rooms for staff and two lecture rooms, has a laboratory for about twenty students, equipped for surveying and engineering drawing as well as for practical classes in forest botany and wood anatomy. There are a large library and reading room and a museum of corresponding dimensions which it is proposed to fill with a variety of exhibits, including dioramas illustrating forests under various systems of management. In addition, the semi-basement contains photographic dark-rooms, a large and well-equipped wood-working shop and a store for the tools, surveying instruments, etc., used by the forestry students in their practical training.

The Botany Department has on the ground floor a lecture room seating 120, a small museum, a

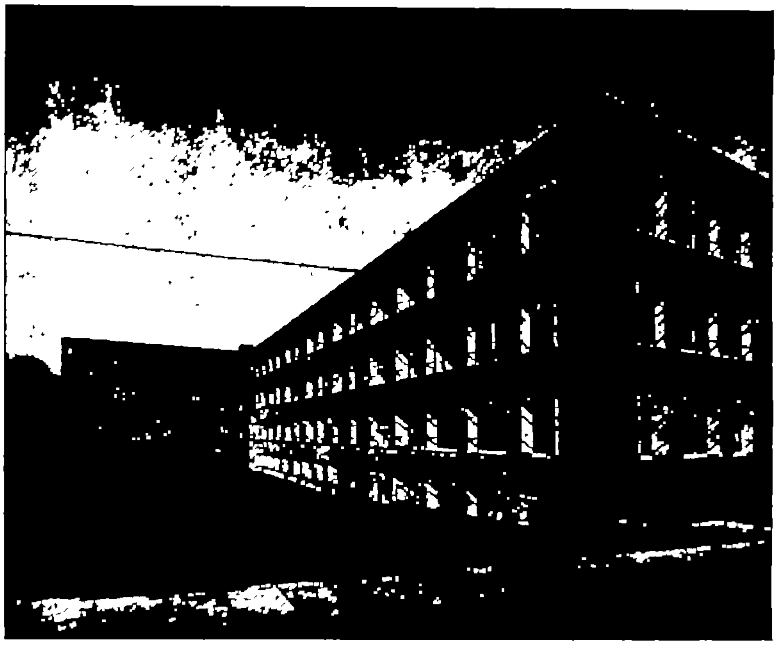

Fig. 2. Botany–Forestry Building, Bangor

herbarium and a research laboratory specially equipped for work on marine and freshwater algae as well as rooms for staff and postgraduate research workers. Further accommodation for staff and post-graduate students is provided on the first floor, which also houses a small lecture room (seating seventy), the library and separate reading room.

On the top floor, which is wholly allotted to botany, there are two large teaching laboratories for general botany, providing places for sixty-two and forty-eight students, respectively. Since these laboratories are placed back to back and divided only by swing doors, they can when occasion demands be treated as a single unit. In these and in the small honours work laboratory (capacity sixteen students) there is ample space for demonstrations and (as in the forestry laboratory) each student is provided with an adjustable 'Anglepoise' lamp and a microscope lamp made to the Department's specification. Only a limited amount of overhead lighting is provided. The small laboratory for advanced mycology is similarly designed.

Also on the top floor are the laboratories for plant physiology. The teaching laboratory, holding sixty students, resembles a well-equipped chemical laboratory. The benches are provided with electrically heated water baths, but not gas, and there are vacuum and compressed air points. There is overhead fluorescent lighting and an adjacent balance room. Near by is a small research laboratory and preparation room.

The semi-basement, in addition to housing the Forestry Department's wood-working shop and instruments store previously mentioned, provides the Botany Department with two photographic dark-rooms, a general photographic room, a workshop and sorting room and two constant-temperature rooms.

In his introductory speech at the opening ceremony. Lord Kenyon, president of the College, said that the completion of the new science buildings was an event second in importance only to the opening of the College itself. He expressed the thanks of the College to the University Grants Committee for the financial support which had made the post-war building programme possible.

Sir Keith Murray then spoke of the significance of the occasion as marking the increasing importance of science, and especially of biology, to-day. That the College had found it necessary to increase the accommodation for all its science departments and not only for some of them illustrated the breakdown of the lines of demarcation between the different sciences and the need for training in the fundamental sciences as the basis of all scientific education.

After emphasizing the growing importance of the biological sciences because of the rise in world population and the consequent pressure on food supply and other natural resources, Sir Keith went on to say that the duty of a university is to turn out men and women with minds which are trained and not merely stored with facts; this training should be carried out not merely by formal instruction in the lecture room and laboratory, but by informal contacts between the students and the more mature minds of their teachers, as well as by the contacts of student with student in daily work and extra-curricular activities. The latter are as valuable a part of a university education as the work covered by the examination syllabus.

Sir Keith Murray was thanked by Sir Emrys Evans, principal of the College, and finally the College's gratitude to the architect and the contractors was expressed by Sir Wynn Wheldon and Lady Artemus-Jones, vice-presidents.

---

# PLANT GROWTH SUBSTANCES

## THIRD INTERNATIONAL CONFERENCE

THE Third International Conference on Plant Growth Substances was held at Wye College (University of London) during July 17–22. The organizer was Prof. R. L. Wain, head of the Department of Chemistry in the College and director of the Agricultural Research Council Unit for Plant Growth Substances and Systemic Fungicides. D. F. Wightman acted as conference secretary.

The emphasis of the papers and discussions was on the biochemical aspects of the subject but not confined, as in the preceding conference at Lund in 1953, to considerations of the relationships between chemical structure and biological activity. Although two whole sessions were devoted to this topic, the remaining four on the natural auxins, auxin metabolism and mechanism of action promoted the more vigorous discussions.

The two years that have elapsed since the Lund Conference have seen the almost universal adoption of paper partition chromatography as a tool in the study of naturally occurring plant growth substances. The opening session of the Conference clearly demonstrated how valuable this new tool has been in tackling the involved problems of the nature of the natural auxins. Dr. J. P. Nitsch (Harvard University), in a systematic study of extraction, separation and assay methods, has revealed the dangers of using ether as a solvent for extractions in the cold since enzyme activity may still persist in this solvent. Absolute methanol or ethanol are much to be preferred. He also demonstrated how different solvents could change the pattern of active substances extracted, thus illustrating the dangers of too narrow an application of stereotyped techniques. Another, until recently unsuspected, danger was the use of ammonia as a component of the chromatographic solvent for the separation of acid growth substances. Considerable hydrolysis of certain substances may occur during the running of the chromatogram. This presumably accounts for the interconversions of neutral auxin precursors extracted from a variety of plant tissues by Dr. J. A. Bentley and Mr. S. Housley (University of Manchester). Dr. Nitsch also introduced a new assay technique, using segments from the first internode of oat seedlings. This he claims has a sensitivity greater than that of the oat coleoptile curvature test and can measure quantities of indole-3-acetic acid of the order of 0·001 μgm. This makes it possible to study small quantities of tissue such as apical meristems, 200 mgm. of which is sufficient to allow an accurate assay. In a number of papers and in the discussions which followed, the reliability of the usual colorimetric tests for indole compounds came under review. Both Dr. Nitsch and Dr. A. J. Vlitos (New York) have perfected reliable quantitative methods for measuring colour intensity of spots on paper chromatograms, allowing accurate estimations of indole compounds when present in relatively high concentrations.

Chromatographic techniques in the hands of Prof. Hans Soding and Dr. Edith Raadts (Hamburg) have been turned to the solution of the old enigma of the nature of auxin in the oat coleoptile. Indole-3-acetic acid was found in quantity in the diffusates from apex and base of that organ together with an unidentified growth-promoting substance. Two growth inhibitors and a precursor of indole-3-acetic acid were also isolated. Similar techniques have been employed at Wye College to study changes in growth substance content of the various organs of germinating seedlings (Miss P. M. Cartwright, Mr. J. T. Sykes and Prof. R. L. Wain). The results point to the conclusion that indole-3-acetic acid has no part to play in the germination processes themselves but is important in the growth of the young shoot. One interesting point was the detection of indole-3-carboxylic acid in these seedling extracts, a compound which might be derived from indole-3-acetonitrile by α-oxidation, as shown in the contribution of Mr. R. C. Seeley and his collaborators (Wye College).

Exciting discoveries of new growth substances from the endosperms of seeds were announced by Prof. F. C. Steward (Cornell University). Using a new technique of plant tissue culture, permitting the study of free-floating cells, the separate effects of natural growth substances on cell division, cell expansion and cell differentiation could be followed. Four nitrogenous substances, highly active in stimulating cell divisions, have been isolated from coconut milk by heavy-metal precipitations. One of these substances has been identified unequivocally as 1-3-diphenyl-urea. Its action has been confirmed on carrot, artichoke and potato tissue. Nitrogen-free substances with a similar action have been extracted from immature *Aesculus* fruits and from coconut milk. These substances belong to the general class of leucoanthocyanins, although their final identity is not yet known. It seems, therefore, that the power of stimulating the cell to divide is not the sole prerogative of any single molecule.

The sessions on the relationships between chemical structure and biological activity in the auxins received the greatest share of the formal papers. Prof. H. Veldstra (University of Leyden), in a review of recent advances, directed attention to a range of new substituted benzoic acids the structure-activity relationships of which point strongly to a physicochemical action of the molecule acting via its stereochemical relationships rather than to a purely chemical combination with a receptor at specific reactive points in the molecule. This was to some extent emphasized by the results of Dr. L. C. Luckwill and D. Woodcock (Long Ashton, Bristol), who pointed out that the effects of chlorine substitution in the 2-naphthoxyacetic acids would, on a chemical combination hypothesis, require the unlikely postulate of a specific combination of receptor with five separate points in the auxin molecule. Prof. Veldstra pointed to another interesting development, namely, the discovery that the carboxymethyl-N : N-dialkyldithiocarbamates are active as auxins. This is the first case of an active compound not possessing an unsaturated ring and adds considerable support to Veldstra's physico-chemical hypothesis of auxin activity. Previous work had strongly suggested that in the optically active propionic acid series of synthetic auxins (+) forms were almost always active, whereas the corresponding (−) forms were inactive or auxin antagonists. The work of Dr. J. M. F. Leaper (Ambler, Pennsylvania) and Dr. B. Åberg (University of Uppsala) with the naphthalene derivatives showed this to be an over-simplification, since both forms can be auxins, their relative activities depending on the test plant employed. Prof. R. L. Wain and colleagues (Wye College) described extensive experiments in the structure-activity relationships of homologous series of ω-(2,4-dichlorophenoxy)-alkane carboxylic acids, amides and nitriles. It was shown that the alternation of activity with increasing side-chain length in both acids and amides could be correlated with the appearance of 2,4-dichlorophenoxyacetic acid in the tissue, presumably produced by the β-oxidation of the side-chain. With the nitriles, all homologues showed activity, suggesting the hydrolysis of both —CN and —CH$_2$CN groups to —COOH. A similar alternation of activity in the tomato ovary test was shown by Dr. L. C. Luckwill and D. Woodcock (Long Ashton, Bristol) for the 2-naphthyloxy- series of acids, but here β-oxidation was blocked completely by chlorine substitution in the 3 position in the ring, only the acetic acid being active.

The controversial questions concerning the structure–activity relationships of 'anti-auxins' in root growth were discussed by Dr. B. Åberg (University of Uppsala) and Prof. Hans Burström (University of Lund). Dr. Åberg demonstrated that much of the conflicting evidence from previous work may have been due to the use of different test materials, since wheat roots are much more sensitive and more easily stimulated by anti-auxins than flax roots. In the phenoxy-*iso*-butyric acids and some other similar anti-auxins which stimulate root growth, para-substitution in the ring was shown greatly to increase activity. The dangers of using gross elongation of roots as a measure of activity in these compounds was pointed out by Prof. Burström from a study of the interactions of β-naphthoxyacetic acid (inhibiting auxin), three of its chloro-substituted derivatives, indole-3-acetic acid and α-(3-indole)-*iso*-butyric acid (anti-auxin). There seems to be two phases in root cell elongation on which different compounds may have different actions, may also show different mutual interaction patterns or may not interact at all. The great importance, therefore, of paying due attention to the heterogeneity of the cell elongation mechanism in structure–activity studies was heavily stressed. Out of these considerations active discussion turned on the role of indole-3-acetic acid in normal root growth. No measure of agreement was reached.

Much attention was paid to theoretical considerations underlying structure–activity relationships. Dr. J. van Overbeek (Modesto, California), in a consideration of the properties of a group of suspected auxin antagonists, the maleimides, and a new class of plant growth inhibitors, the phosphenoxides, showed that a close relationship exists between activity and lipoid solubility and suggested, therefore, that ease of penetration through protoplasmic membranes might explain structure–activity relationships. Drs. H. Linser and K. Kaindl (Linz) discussed the relationships of molecular shape and size to stimulatory and inhibitory activity in oat coleoptile growth. An extensive mathematical treatment of the curves relating applied concentration to growth response to single substances and mixtures, based on the concept of molecules competing for various receptor 'holes' at growth centres in the cell, was subjected to some criticism by the physiologists. It was felt that such a simple concept ignored both the fundamental differences in action which must exist between auxins and toxic inhibitors such as eosin and also the possibility of metabolic interactions. This view was supported by the finding of Prof. L. J. Audus and Miss R. Thresh (Bedford College, London) that the auxin antagonist 2,3,5-tri-iodobenzoic acid may exert its physiological actions by lowering dramatically the level of endogenous indole-3-acetic acid in plant tissues. The application of the methods of enzyme kinetics to the study of auxin–anti-auxin interactions, as developed by Prof. J. Bonner (California Institute of Technology), came under full discussion. It was agreed that the technique had its uses, provided it was applied with the greatest circumspection.

Some four or so papers were concerned with the metabolism of indole-3-acetic acid and related compounds in the plant. In a critical review of the biogenesis of this compound, Dr. S. A. Gordon (Lemont) considered new data bearing on the pathways of its production from tryptophan. The current view is that it may be degraded to indole-3-acetaldehyde via either tryptamine or indole-3-pyruvic acid and thence via the aldehyde to indole-3-acetic acid. Alternatively the pathway suggested is a branching at the iminopropionic acid to yield the acetonitrile, which is then hydrolysed to indole-3-acetic acid via the acetamide. However, various considerations were discussed which indicate that the above specific pathways, though potentially operative in plants, do not normally function in indole-3-acetic acid formation. The hypothesis was presented that tryptophan goes to indole-3-acetic acid via a sequence analogous to the pyruvate dehydrogenase mechanism, that is, indole-3-pyruvic acid to indole-3-acetic acid through the acyl lipoate directly or through the coenzyme A ester. The differing abilities of various plant species to hydrolyse indole-3-acetamide and indole-3-acetonitrile to indole-3-acetic acid were clearly demonstrated by Mr. R. C. Seely and collaborators at Wye College. Thus the amide is extensively converted to the acid by pea, tomato and maize tissue but not by wheat and celery, whereas the nitrile is converted by wheat and maize but not by the other tissues. The fate of indole-3-acetic acid fed in high concentrations to tissues was discussed by Dr. A. W. Galston (California Institute of Technology), who showed that a fraction may be actively bound to cytoplasmic proteins. The greater portion, however, is oxidized by the action of a peroxidase system induced by the high indole-3-acetic acid concentrations applied. Both the peroxidase and the peroxide-producing moieties of the total system are so induced. It was suggested that this phenomenon accounts for the normal cessation of cell elongation and the subsequent onset of lignification by the oxidation of lignin precursors of the eugenol type by this induced peroxidase system.

Little attention was given to the role of indole-3-acetic acid in physiological processes in plants. Prof. P. Larsen (University of Bergen) presented data on geotropic responses of roots pointing to the validity of the classical Went–Cholodny theory. The role of auxin in the flowering of short-day plants was discussed by Dr. A. J. Vlitos (Boyce Thompson Institute, New York). Contrary to current theories, indole-3-acetic acid levels in short-day photoinduced plants of Biloxi soy bean and Maryland Mammoth tobacco are much higher than in non-induced plants.

The final session of the conference was devoted to papers and discussion on the mechanism of auxin action. Prof. J. Bonner (California Institute of Technology), in an extensive investigation into the osmotic relations of growing oat coleoptile segments, returned to the conclusions put forward a quarter of a century earlier by Heyn, that the ultimate action of auxin must be in the cell wall. In an elegant series of experiments in which segments were treated with indole-3-acetic acid and then prevented from growing by osmotic means, he demonstrated a persistent effect on wall properties independent of any effect arising as a result of growth. Water permeability was dismissed as a possible factor, from studies with deuterium-labelled water. The results of extensive studies on auxins and absorptive processes were presented by Prof. G. E. Blackman (University of Oxford). The actions of 2,4-dichlorophenoxyacetic acid on growth and absorption of nitrogen, phosphorus and potassium are not obviously related. *Lemna minor* and *Salvinia natans* differ considerably in their responses. Radioactively labelled 2,4-dichlorophenoxyacetic acid is rapidly taken up by these plants, but after four hours a loss from the tissues is observed. The temperature sensitivity of this loss suggests that it is not an exchange action but an active export of the auxin molecule. Pretreatment of plants with very dilute solutions of the acid considerably reduces subsequent uptake, giving a possible explanation of the reduced sensitivity of such pre-treated plants to toxic levels of 2,4-dichlorophenoxyacetic acid treatment. The role of coenzyme A in growth processes mediated by auxin was discussed by Dr. A. C. Leopold (Purdue University, United States). Most striking was the effectiveness of supposed anti-auxins, for example, 2,3,5-tri-iodobenzoic acid, 2,4-dichloranisole and coumarin, in blocking the effective —SH groups in the coenzyme. The inadequacies of a previous theory of growth substances action based on coenzyme A esterification were discussed in the light of new findings. Prof. T. A. Bennet-Clark (King's College, London) presented a new theory to explain auxin action on cell wall extensibility. Evidence was presented that this extensibility might be closely bound up with the state of pectic substances in the growing cell wall and the nature and intensity of the cross-linking forces between the molecules. Further evidence suggested that methylation of these pectic substances and also their relationships with calcium ions might play a part in wall changes and that choline and choline-esterase might be involved. The marked inhibiting action of indole-3-acetic acid on choline esterase activity adds support to these views. Other views on possible mechanisms were expressed during the conference. Prof. H. Veldstra directed particular attention to nucleic acid metabolism, an aspect so far neglected in auxin studies. Prof. F. C. Steward made a similar plea for nitrogen metabolism.

The papers given at the conference are to be published in a special volume which, it is hoped, will appear well before the end of the year.

L. J. AUDUS

# RELATION OF GENETICS TO POPULATION STUDIES

A WELL-ATTENDED joint session of Sections D, I and J (Zoology, Physiology and Psychology) of the British Association took place in Bristol on September 2, the general topic being "Genetics and Medicine".

In the opening paper, Dr. H. Grüneberg (University College, London) discussed the use of "Inherited Diseases in Animals as a Tool in Medical Research". The laboratory rodents have provided a large number of inherited conditions, including many with close counterparts in man. Many of these are caused by single genes; but equally important are inherited diseases conditioned by an array of genes which occur in a high frequency in some inbred strains, but are rare or absent in others. The use of this material opens up certain important fields of research which are inaccessible in man himself. The majority of inherited diseases and anomalies due to single genes arise in early development, and as early human embryos with the initial phases of such anomalies are scarcely ever available for study, a step-by-step investigation of abnormal development is entirely dependent on animal material.

Direct observation shows that the mechanisms underlying abnormal development are often quite different from those of classical pathology. For example, a reduction of the vertebral bodies with absence of the odontoid process of the axis in a mouse mutant is due to an early degeneration of the notochord. Widespread skeletal anomalies associated with the gene for congenital hydrocephalus in the same animal are due to general reduction in size of the mesenchymal skeleton as it is formed, and threshold mechanisms determine the absence of some elements, fusions between others, etc. In a third instance, anomalies of the vertebral column, again in the mouse, are traceable to a faulty distribution of mesenchymal material, too much being used for the intervertebral disks and too little for the vertebræ themselves.

The pathology of development is thus a new field entirely dependent on animal material. The discovery of several inherited types of deafness in the mouse is likely to assist in the understanding of the pathology of human deafness, which is greatly hampered by technical difficulties not encountered in animal material. Important progress has been made by the use of resistant and susceptible strains of animals in analysing the physiological basis for disease resistance. The use of animal material for studying diseases of old age, so familiar in cancer research, was illustrated by amyloid degeneration and cystic kidney disease in a certain strain of mice and its absence in others; what could scarcely have been discovered in man is the fact that this inherited tendency to amyloidosis can be almost completely suppressed on certain low-protein diets.

In a paper on the "Causation in Mental Deficiencies", Dr. J. A. Fraser Roberts (London School of Hygiene and Tropical Medicine) pointed out that gene differences in certain rare types of mental deficiency have provided important general information; for example, the first estimate of an autosomal mutation-rate in vertebrates was made with tuberose sclerosis (epiloia). There is evidence that some modest proportion of severe mental deficiency, in addition to a few rare special types, is determined by recessive genes. The great bulk of mental deficiency, however, is a heterogeneous collection the causation of which presents difficult problems. The most useful division of the mental deficiencies is into two groups which may be ascribed to major errors of development, whether genetic or non-genetic. Mild defect shows the signs of some measure of multifactorial determination, together with multiple environmental influences. In spite of the difficulties of measurement, the evidence seems to point to little real underlying overlapping. The incidence of severe defect among the brothers and sisters of those mildly affected is little if at all greater than in the general population. Conversely, apart from the sibs also severely affected, the intelligence of the sibs of those severely affected is little lower on the average than in the general population. Much, or possibly all, the apparent lowering is an artefact due to the methods of sampling. A substantial part of the resemblance between relatives in level of intelligence (including mild mental deficiency) is probably environmental.

Penrose's studies and Dr. Fraser Roberts's own yield a correlation between first cousins which is double what it should be, given the correlation between sibs. It seems reasonable to conclude that while the genes in common are reduced to one-quarter in cousins as against sibs, environmental similarities fall off much more slowly as relationship becomes more remote. It is possible that some major non-genetic causes affecting intelligence adversely may be identified. For example, there is the definite lowering in twins, as found in the Scottish survey. There is also the evidence that prematurity is much commoner among high-grade and borderline defectives than in the general population.

Dr. E. T. O. Slater (Genetic Unit, Institute of Psychiatry, University of London) gave a brief general report on "Work on Twins in Psychological Medicine", in which he reviewed particularly twin studies on the causes of schizophrenia and of criminality; in the latter, earlier studies had suggested a predominant influence of heredity; but in more recent work, factors like early background and family tradition, special opportunities and temptations have now emerged as significant causes. In Dr. Slater's own work (jointly with Mr. James Shields) on the causes of 'neurosis', the comparison between monozygotic and dizygotic twin pairs has produced evidence that the tendency to neurosis is, at least in part, under genetic control.

The main emphasis of the work was, however, on the environmental causes of the breakdown. These were studied through the differences which were found between the partners of monozygotic twin pairs, the differences being caused by the inter-twin relationship (one twin tending to take on more of the leadership, etc.), the relationship with parents, the marital relationship, by differences in occupational stress and of physical health, and finally by differences in psychological stress other than those covered above. In nearly all cases, causes are multiple, though very often a single factor can be picked out as the most important. Generally, Dr. Slater considers that the causes of neurotic illness are intelligible at a common-sense level and do not seem to require recondite hypotheses. Among causes operating from early in child life, those which persist for years (for example, the type of training) seem to be the most important.

Prof. L. S. Penrose (Galton Laboratory, University College, London) demonstrated in his paper on "Mutation and Parental Age" that human material may in certain cases yield results superior to those usually obtained from experimental animals. The spontaneous mutation-rates of a number of ('dominant') human genes have been estimated by direct observation of freshly arising cases, that is, of abnormal children born of normal parents. In other cases, an indirect method has been used which is based on the supposition that elimination by selection of a gene with deleterious effects must be balanced by newly arising mutations, the overall frequency of the condition remaining approximately constant.

Additional information about possible causes of mutations has now been obtained from a consideration of parental age. For example, if a certain gene is particularly sensitive to ionizing radiation to which parents are exposed throughout their lives, mutations at that locus will be proportional to parental age such that the trait will be twice as common among offspring of parents aged forty as among those with parents aged twenty years. Looked at in another way, the parents of children carrying newly mutated genes will be older than the average parent. Some evidence (unfortunately from maternal ages only) of an increase of mutation-rate with age comes from microphthalmia, and there is less complete evidence of an effect of both paternal and maternal age in the case of epiloia and retinoblastoma. The incidence of achondroplasia (born of normal parents and hence presumably due to a new mutation) depends strikingly on the age of the father, but there seems to be little or no effect of the age of the mother; in the latter case, a possible interpretation is that, while the epiloia locus is sensitive to natural radiation, the achondroplasia locus is sensitive to agencies specially active at some stage in cell division, perhaps chemical mutagens. The relative absence of cell division in the female germ track, as compared with the male germ track, would explain the lack of independent maternal effects. The dependence or otherwise of mutation-rate on parental age thus affords some information on possible causes of 'spontaneous' mutations not so far obtainable from data on spontaneous mutations in animals.

The concluding paper, by Dr. C. O. Carter (secretary, Eugenics Society), dealt with "Genetics and Child Health". In recent years, deaths from diseases of childhood due to environmental causes (mainly infections) have declined sharply. As a result, the groups of diseases mainly or partly due to genetical causes loom much larger. An indication of the changes in relative importance is given by the cause of death in two hundred consecutive children undergoing post-mortem investigation in a children's hospital in each of the years 1914 and 1954. The group of diseases caused by environment was more than two-thirds of the whole in 1914, but less than one-seventh in 1954; the group of diseases mainly genetical in origin was only one-fiftieth of the whole in 1914 but one-eighth in 1954; diseases of mixed causation were less than one-seventh of the whole in 1914, but more than a quarter in 1954, while diseases of unknown causation rose from less than a quarter in 1914 to nearly a half in 1954.

Looking to the future, Dr. Carter believes that, while the environmentally caused group of diseases will continue to fall, the diseases of mixed origin will probably be only slightly reduced by environmental measures. Reduction in the proportion of children born with genes predisposing to these disorders can only be achieved by reducing the average number of generations through which disadvantageous gene mutations can persist in the population. At the moment, such mutations are tending to last longer as new methods of treatment keep those affected alive to an age at which they can bear children. Probably the most ethically correct way of bringing about a reduction in the average number of generations a mutation persists is to enlist the co-operation of parents who are unlucky enough to carry major disadvantageous mutations, in planning to keep the number of their children below replacement-rate.

# OBITUARIES

## Prof. J. C. Flugel

Prof. John Carl Flugel died suddenly at his home in London on August 6. He was one of the few survivors of the small band of British psychologists who received their training at Oxford under William McDougall. McDougall's views on the nature of mind and the way psychological questions should be approached influenced nearly all that Flugel wrote; yet he himself succeeded in developing a wholly original attitude.

His earliest researches were carried out in the laboratory at Oxford, and dealt with such practical problems as intelligence testing, visual adaptation at night, the measurement of mental fatigue and the causes of the oscillations of attention. After his appointment as lecturer at University College, London, he remained for many years in charge of the experimental work in the Department of Psychology. His chief interest, however, lay in the deeper problems such as in those days were relegated to the somewhat dubious regions of psychoanalytic study and psychical research. He was the first professional psychologist to make a serious examination of Freud's early theories. These he endeavoured to re-interpret in terms of current British psychology. Thus, while the medical profession still looked askance at the novel and extravagant doctrines of the Freudian School, he did much to popularize their chief conclusions by recasting them in a more acceptable form. The outcome was a series of papers on psycho-analytical topics which appeared in various scientific journals, and were later collected and re-issued in book form.

Of his larger works, the first was "The Psycho-analytic Study of the Family" (1921), which attracted immediate attention. The most popular was probably his "Psychology of Clothes" (1930). "A Hundred Years of Psychology" (1933) presents an admirable historical review of the development of psychology from 1833 to the date of publication, and is still read as a regular text-book. The lucid style, the flashes of humour, the widespread sympathy and tolerance which distinguish all his writings were also a marked feature of his personal teaching, and endeared him to numerous students who came to his classes from all over the world.

In 1929 Flugel was made assistant professor, and retained this post until his retirement in 1944. A good deal of his time was spent in practical psycho-analytical work with patients and normal persons; and the results led to many valuable contributions to psychological and psychiatric theory. The more important were embodied in his books on "Men and their Motives" (1934) and "Man, Morals, and Society" (1945). He served for some time as honorary secretary of the International Psychoanalytic Association; and in 1948 was elected chairman of the programme committee of the International Congress on Mental Health. Two years later he was appointed president of Section J (Psychology) of the British Association.

To the end of his life Flugel continued to give regular lectures at University College and to take an active part in the work of the British Psychological Society and its numerous committees. But his abiding work lies in his fruitful attempts to synthesize Freudian psychoanalysis with the orthodox tenets of British psychology as taught by Ward, Stout and McDougall.

Cyril Burt

## Mr. Philip Lyle

Philip Lyle, who died on July 15, was the elder son of the late John Lyle, of Weybridge, and grandson of Abram Lyle, the founder of the sugar-refining company which was later amalgamated with Henry Tate and Sons to form Tate and Lyle, Ltd. He was born on November 26, 1885, and was educated at Rugby, in Switzerland and at University College, London. He later applied himself to statistical mathematics, which he put to very good use in the sugar industry.

As a director of Tate and Lyle, first at Plaistow refinery, Philip Lyle participated in raising the low thermal efficiency, poor scientific control and low output of the refinery until it held one of the foremost positions in the world. He paid special attention to losses incurred in sugar refining and consequently to methods of sugar analysis. In 1947 he was responsible for broadening the Company's outlook towards research and enlarging its research activities. As chairman of the Research and Development Committee he was invaluable in guidance and judgment.

Mr. Lyle's own scientific contributions were best known in refinery circles; but a few exceptions include "Heat of Solution of Sucrose", which explained discrepancies in heat balances in refineries. The "Sugar Industry" and "Constructions of Nomograms for use in Statistics" appeared in the *Journal of the Royal Statistical Society* and *Applied Statistics*, respectively. He was a notable member of both the Royal Statistical Society and its Industrial Applications Section, being one of the two secretaries and editors of the former and on the Editorial Committee of the latter. In 1944 he published "Regression Analysis of Production Costs and Factory Operations".

Philip Lyle was a director of the West Indies Sugar Co. of Jamaica, and Caroni, Ltd., of Trinidad. He made a special study of statistical treatment of agronomical problems. He was also a director of Colonial Yeast, Ltd., which had been founded by the Sugar Commission to produce cheap protein and vitamins (Thaysen's *Torula utilis*) needed in the Caribbean, from surplus cane molasses. The product could not find a market there or elsewhere, and the project was abandoned; but his faith in the necessity for protein production to supply under-nourished peoples was unfailing, and he read a paper on the subject before the Nutrition Society in 1950.

The Sugar Reorganization Act, 1936, was responsible for formation of Research Committees *A* and *B*, of which he was a member. The programme for *B* was largely that put forward by him and was adopted in part by the Colonial Research Committee. Other proposals were chemical research into by-product utilization and sucro-chemistry, which were implemented at the University of Birmingham under Sir Norman Haworth and later Prof. L. F. Wiggins. Physico-chemical research at the University of Bristol was financed first by the Commission and later by Tate and Lyle and the British Sugar Corporation.

Among unpublished work which has nevertheless been widely adopted and utilized is his "Analysis of Sugar Grists", in which he showed that the normal frequency curves allowed grists to be expressed in terms of mean aperture and coefficient of variation.

So much for his interests and work. What of the man? To meet Philip Lyle was to like him. To know him was to admire, respect and love him. His encouraging manner, his friendly approach, his sunny smile (the same to people in all walks of life) made everyone his friend, and effort on his behalf a pleasure; Browning might have altered the lettering of "Pippa passes". He leaves a widow, a daughter, two sons, one of whom is following in his footsteps, several grandchildren and innumerable friends.

H. O. S. de Whalley

## Sir Francis McClean

Frank McClean was best known to the outside world as the great patron of aviation and the founder of amateur and naval flying in Great Britain. Born on February 1, 1876, and educated at Charterhouse, Clifton and Coopers Hill, he served with the Public Works Department in India during 1898–1902. After flying in two Gordon-Bennett balloon races in 1907–8, he flew with Wilbur Wright at Le Mans in the latter year. He bought land in the Isle of Sheppey for his early flying experiences on heavier-than-air machines and lent aircraft to the Admiralty so that naval officers could learn to fly. After some pioneering work in submarine photography, he caused some sensation by flying up the Thames in a seaplane, passing between the upper and lower parts of the Tower Bridge and under London Bridge. He joined the R.N.A.S. on the outbreak of the First World War, served on Channel patrol and then became chief instructor at Eastchurch. When the R.A.F. was formed he took a commission, but resigned in 1919.

McClean's other great interest lay in astronomy; in this he was influenced by his father, Dr. Frank McClean. He organized two eclipse expeditions, to Flint Island in 1908 and to Port Davey in Tasmania in 1910. He also joined an expedition led by Sir Norman Lockyer to Vavau Island in 1911. He was a joint founder of the Norman Lockyer Observatory on Salcombe Hill, Sidmouth, serving under his friend, Sir Richard Gregory, on its council. The Frank McClean Dome and the twin telescope and sidereal clock which it houses bear further witness to his generosity. His 21-in. siderostat, bought for his eclipse expeditions, was presented by him to the Cambridge Observatories. With his brothers, he was a generous benefactor also to the Coins and Manuscripts Departments of the Fitzwilliam Museum, Cambridge. Other social activities are reflected in his holding the office of High Sheriff of Oxfordshire in 1932 and the presidency of the Royal Aero Club for two spells. He was the senior member of the Royal Astronomical Society Club, and was much loved by a wide circle of friends in flying and astronomical circles. He died on August 11 after a long illness, leaving a widow and two daughters.

# NEWS and VIEWS

## Chemistry at Nottingham:

### Prof. F. E. King, F.R.S.

PROF. F. E. KING, who has recently resigned the Sir Jesse Boot chair of chemistry in the University of Nottingham to become director in charge of research at British Celanese, Ltd., carried out his earliest researches with Prof. J. R. Partington in the University of London, mainly on inorganic and physical chemical subjects. He then went to Oxford, where he became in turn demonstrator and lecturer in the Dyson Perrins Laboratory, and also lecturer in organic chemistry at Magdalen and at Balliol Colleges. His work at Oxford covered a wide field; but particularly noteworthy, in chronological order, were the long series of papers which Sir Robert Robinson and he published on the chemistry of eserine (physostigmine) and on laudanosine; his work on potential chemotherapeutic agents, particularly derivatives of quinoxalines, iminazoles, cinnolines and arylamines; and his work on the structure of extractives from hardwoods. This very difficult branch of natural-product chemistry has been his major interest during recent years, and he has obtained some conspicuously successful results, for example, the elucidation of the structure of ferreirin and homoferreirin obtained from the heartwood of *Ferreirea spectabilis*. British Celanese, Ltd., is providing facilities for the continuation of this work under Prof. King's supervision. He was elected to the chair at Nottingham in 1948 and to fellowship of the Royal Society in 1954.

### Prof. A. W. Johnson

DR. A. W. JOHNSON, who succeeds Prof. King at Nottingham, received his early training at the Imperial College of Science and Technology, London, after two years of preliminary industrial experience. He remained at the Imperial College during 1936–42, his research work being chiefly on the synthesis of vitamin A. For the next four years he was research chemist at the Dyestuffs Division of Imperial Chemical Industries, Ltd., where he worked mainly on the chemistry of acetylene, which was then a rapidly developing subject and upon which he wrote a two-volume treatise that appeared in 1946 and 1950. In 1946 he went to the University of Cambridge, where he was appointed assistant director of research and, later, University lecturer in chemistry, and was also elected Fellow and Steward of Christ's College. His work at Cambridge with Sir Alexander Todd has been mainly on the chemistry of the tropolones and on the constitution of the deeply coloured compounds isolated from certain species of aphids, and later upon the structure of vitamin $B_{12}$. The work on this vitamin has been carried out in collaboration with the chemical staff of Glaxo Laboratories, Ltd., and ultimately with the help in the crystallographic field of Dr. Dorothy Crowfoot Hodgkin and others; all the main points in the structure of this vitamin have thus now been elucidated (see *Nature*, August 20, p. 325). Dr. Johnson was awarded the Meldola Medal of the Royal Institute of Chemistry in 1946, and was Tilden Lecturer of the Chemical Society in 1953. Prof. King's resignation has deprived the University of Nottingham of an outstanding teacher and research worker; but the University is indeed fortunate in securing, in Dr. Johnson, a successor who also possesses this invaluable combination of qualities.

## Veterinary Pathology at Liverpool:

### Prof. D. L. Hughes

MR. D. L. HUGHES, head of the Veterinary Science Division of Messrs. Boots Pure Drug Co., Ltd., has been appointed to the chair of veterinary pathology in the University of Liverpool in succession to Prof. R. E. Glover, who has become principal and dean of the Royal Veterinary College, London. Prof. Hughes is well known even beyond the confines of his own profession, both as a research bacteriologist and administrator. Born in 1912, he studied at the Royal Veterinary College and obtained the diploma of membership of the Royal College of Veterinary Surgeons in 1934; two years later he was awarded the diploma in bacteriology of the University of London, and more recently the fellowship of the Royal College. Being keenly interested in research and particularly in the bacteriology of animal disease, Hughes quickly established a reputation for integrity and accuracy at the bench and in the written and spoken word. Although he is probably best known for his researches into bovine mastitis, undertaken principally while on the staff of the Agricultural Research Council's Field Station at Compton, and later at the veterinary laboratories of Messrs. Boots Pure Drug Co., Ltd., his published works command wider horizons and are not confined to bacteriology alone. Outside the laboratory he brings to the roles of administrator, lecturer and committee man the attribute of a quiet and direct manner; to the British Veterinary Association he gives much time and energy as an active member of its Council and as chairman of the editorial committee of the *Veterinary Record*. His many friends and colleagues will wish him the best of good fortune in his new appointment.

## Council of Scientific and Industrial Research, India:

### Prof. M. S. Thacker

PROF. M. S. THACKER has been appointed director of the Council of Scientific and Industrial Research, India, in succession to the late Sir Shanti Bhatnagar. Born on December 3, 1904, he received his early education at Ahmedabad and Bombay, and graduated in engineering from the University of Bristol in 1927. He worked as electrical engineer with Bristol Corporation until 1931. He then joined the Calcutta Electric Supply Corporation and served there as a senior technical officer until 1947. In that year he joined the Indian Institute of Science, Bangalore, as head of the Power Engineering Department, and in 1949 he was appointed director of the Institute. Prof. Thacker is a member of several learned scientific and professional bodies in India, the United Kingdom and the United States. He has been associated as delegate with the International Commission on Large Dams, the International Conference on Large Electricity Systems, Paris, the World Power Conference, the World Metallurgical Congress and the Unesco Advisory Committee on Arid Zone Research; at the New Delhi session in October 1954 he was elected chairman of the Committee on Arid Zone Research. Prof. Thacker has served on the Board of Scientific and Industrial Research and the Board of Engineering Research of the Council of Scientific and Industrial Research, India. In the Republic of India Day honours on January 26, 1955, Prof. Thacker was the recipient of the award of Padma Bhushan.

## The British Institution of Radio Engineers: Premiums for 1954

The British Institution of Radio Engineers has awarded the following premiums for papers on the subjects indicated, published in the *Journal* of the Institution during 1954: *Clerk Maxwell Premium* (the premier award of the Institution), to F. N. H. Robinson (Clarendon Laboratory, Oxford), microwave shot noise in electron beams and the minimum noise factor of travelling-wave tubes and klystrons; *Heinrich Hertz Premium*, to Dr. T. B. Tomlinson (formerly of the University of Southampton), partition components of flicker noise; *Louis Sterling Premium*, to L. H. Bedford (Marconi's Wireless Telegraph Co., Ltd.), problems of television cameras and camera tubes; *Sir J. C. Bose Premium*, to S. Deb (Institute of Radio Physics and Electronics, University of Calcutta), the decay of emission from an oxide-coated cathode due to adsorption of matter liberated from the anode; *Brabazon Premium*, to J. W. Jenkins, J. H. Evans, G. A. G. Wallace and D. Chambers (A. C. Cossor, Ltd.), a high-definition general-purpose radar; *Marconi Premium*, to W. T. Brown (British Telecommunications Research, Ltd.), some factors in the engineering design of very-high-frequency multi-channel telephone equipment; *Leslie McMichael Premium*, to Dr. G. N. Patchett (Bradford Technical College), a critical review of synchronizing separators, with particular reference to correct interlacing; *Students' Premium*, to R. W. Walker (King's College, Newcastle upon Tyne), an electronic random selector. Premiums have also been awarded to the following authors of papers read at the Industrial Electronics Convention, held at Oxford in July 1954: P. Huggins (Sargrove Electronics, Ltd.), statistical computers as applied to industrial control; C. W. Miller (Metropolitan-Vickers Electrical Co., Ltd.), industrial radiography and the linear accelerator; K. Kandiah and D. W. Chambers (Atomic Energy Research Establishment), multi-electrode counting tubes; J. L. Thompson (J. Langham Thompson, Ltd.), wire strain-gauge transducers for the measurement of pressure, force, displacement and acceleration; and M. T. Elvy (Redifon, Ltd.), electronic heating and the woodworking industry.

## The Rubber-Stichting

The Rubber-Stichting (Rubber Foundation), established in 1936 with headquarters in Delft, is one of several research organizations operating in Europe and in the Far East in the interests of natural rubber. Financed by means of a cess levied on rubber produced in Indonesia, the recently announced intention of the Indonesian Government to remove the Foundation to Bogor has come as a severe shock to those interested in research on rubber. The staff, numbering more than two hundred, show little inclination to emigrate, and the possibility of the work in progress being stopped must be faced. The Rubber-Stichting has been engaged in fundamental research for long enough for its work to have won world-wide recognition. It is impossible here even to mention all of it; but of particular significance is its work in the field of latex, which, as a result, can now be used for the direct preparation of chlorinated rubber, rubber hydrochloride, cyclized rubber, and even ebonite. The preparation of reinforced rubber by the formation in the latex of synthetic resin complexes has been of particular interest from both the theoretical and practical points of view. In the laboratories at Delft pilot-plant research has been carried out on flame-resistant latex foam and rubber hydrochloride monofilaments; asphalt-rubber compositions for roads have been developed, a fleet of cars has been used for road-testing experimental tyre compositions, and cement-latex compositions for flooring have been studied. Fundamental investigations have been undertaken relating to vulcanization, abrasion, and the permeability of rubber. It is interesting to recall that out of the fifty papers accepted for presentation at last year's International Rubber Technology Conference, four emanated from the Rubber-Stichting.

A great deal of success has been achieved in publicizing the advantages and possibilities of rubber among technical men in other industries, in the education of rubber technologists, and in the holding of international symposia and conferences on different aspects of rubber technology. An efficient documentation centre for rubber is maintained, especially noteworthy for its work on correlation of rubber patents. In this field it has worked in close co-operation with the Intelligence Division of the Research Association of British Rubber Manufacturers, in which connexion mention must be made of its share in preparing and maintaining the International System for Classification of Rubber Information, the secretariat of which is at Delft.

## Education in East Africa

Four years ago the Nuffield Foundation showed its interest in African education by sponsoring, jointly with the Colonial Office, the Jeffery and Binns Missions. It has now given further assistance to the education of Africans by making a grant of £50,000 towards the work of the Institute of Education at Makerere College, Uganda. A fifth of this sum will provide research accommodation and other facilities for the work of the Institute, while the balance forms an endowment fund enabling a Nuffield Research Fellow to pursue some line of educational study important to East Africa. In choosing the subject of the first research project, it was borne in mind that the Binns Mission had directed attention to the need for better courses in vernacular languages and English in the primary schools of East Africa, and advocated a much earlier start in the teaching of English than hitherto. But little is known about the best methods of teaching English to the children of East Africa, and an imperfect knowledge of the language holds up their education in all subjects well into the secondary school. After consultation with the Directors of Education of East Africa, and with their unanimous support, it has been agreed to devote the first few years of the Nuffield grant to an attack on problems of teaching English and the teaching of other school subjects in English.

## Research on the Tropical Swamps of East and Central Africa

The Nuffield Foundation has given £21,900 for a four-year scheme of research on the biology of tropical swamps, to be directed by Prof. L. C. Beadle, professor of biology in Makerere College, Uganda. The area covered by swamps in East and Central Africa is enormous. In them are accumulating a large proportion of the plant nutrients washed in from the surrounding land which are being preserved under anaerobic conditions. Exploitation by drainage and dry cultivation has begun; but this is not the only, nor, in the long run, necessarily the best method, since the organic matter is rapidly oxidized and the conditions under which it accumulates are destroyed. Wet cultivation of suitable crops (for example, rice) or use of the nutrients for fish culture are possible alternatives. But too little is known about the chemistry and biology of swamps and of the changes which occur on drying. It is the purpose of this scheme to provide information which may assist in framing a long-term policy. The main chemical and microbiological transformations in the water-logged material, the ecology of the swamp vegetation, the biology of the oligochæte worms and other invertebrates and their part in the processes of decomposition, the adaptation of fish to swamp conditions, and the scarcity in untouched swamps of the principal malarial mosquito, *Anopheles gambiae*, are some problems which require investigation. All of them are of practical importance; but there are some aspects which are of fundamental interest—for example, the adaptations to a predominantly anaerobic environment. Work has already been started by Prof. L. C. Beadle in the zoological field and in the botanical field by Dr. Edna M. Lind, reader in biology at Makerere College, and the East Africa Malaria Research Institute has been collaborating. With the new Nuffield grant it is now possible to employ a chemical microbiologist and a zoologist from Europe, and two graduates from Makerere College.

## West African Tsetse Flies

THE taxonomy and systematics of tsetse flies from the Congo region belonging to the *Glossina palpalis* group—that is, to the sub-genus *Nemorhina*—which are of considerable importance from the medical point of view, since they carry human trypanosomiasis, have been the subject of an intensive study by A. de Barros Machado in a work entitled "Révision systématique des Glossines du groupe *palpalis* (Diptera)" (Pub. Cult. No. 22, Museu do Dundo; pp. 189+107 figs.+8 tables; Lisboa: Companhia de Diamantes de Angola, 1954). Intensive collecting was carried out by the author over Angola and the Belgian Congo. Much of the investigation was carried out in the Museum of Dundo; but this was supplemented by work in the British Museum, the London School of Hygiene and Tropical Medicine, the Museum of the Belgian Congo and the University of Porto. Thus practically the whole of the relevant material, including type material, was critically examined and compared. The specimens are carefully described morphologically, particular attention being paid to the copulatory organs and the range of each species and sub-species considered and illustrated. There are no plates; but the excellence of the paper and reproduction of the many photomicrographs renders them unnecessary. The geographical distribution of each form is carefully determined. The one distribution that appears remarkable is that of *Glossina tachinoides*, which has its main centre between long. 10° W. and 20° E. (there is a slip in the text on p. 151 which on line 7 gives longitude 10° E. instead of 10° W.) and a small subsidiary centre in the Sudan near longitude 34° E. As the author points out, another record of this species from the south-west of Arabia cannot be regarded as satisfactorily established. In passing, it is interesting to note that the form along the border of Tanganyika is *Glossina fuscipes martinii*, while that along the Uganda border is *G. fuscipes fuscipes*. The author recognizes and treats fully *Glossina fuscipes*, *G. palpalis* and *G. pallicera*, all of which are polytypic, and *G. tachinoides*. What is known of the ecology and inter-subspecific fertility of the various forms is adequately set forth and discussed. The paper is extremely well printed and will undoubtedly form a classical work of reference for future work.

## Coconut Milk Growth Factors and Tumorous Growth

IN further investigations of the growth and metabolism of plant cells, F. C. Steward, S. M. Caplin and E. M. Shantz (*Ann. Bot.*, N.S., 19, 29; 1955) have considered the phenomenon of tumorous growth in its relation to growth factors of the kind found in coconut milk, that is, the liquid endosperm of *Cocos nucifera*. This new investigation stems from the observation that coconut milk can induce rapid proliferation in cultures of certain mature tissues (carrot root explants consisting of secondary phloem), that is, in cells which would not normally have undergone further division—a result, in short, reminiscent of the growth of plant tumours. These investigators have now shown that aqueous extracts of plant tumours, induced by *Agrobacterium tumefaciens* on *Bryophyllum* and *Kalanchöe*, can be used as a substitute for coconut milk in the tissue-culture procedures used in their laboratory. On the basis of extensive experiments they have shown that tumours of this kind yield extracts possessing a growth-promoting effect similar to that of coconut milk. This effect may be enhanced by, though it is distinguishable from the effect of, added casein hydrolysate in the basic medium. Tumour extracts were consistently more active than extracts of stems and leaves of the same plants, and of normal, non-tumorous plants. The effect of coconut milk, which is replaceable wholly or in part by tumour extracts, is primarily an effect on cell division in the carrot tissue.

## Zygotropism in *Mucor*

IN further physiological studies of the Mucorales, G. H. Banbury has investigated the zygotropism of the zygophores of *Mucor mucedo* (*J. Exp. Bot.*, 6, 17, 235; 1955). In addition to positive zygotropism between (+) and (−) zygophores, there is claimed to be a corresponding 'repulsion' between zygophores of the same mating type, (+) from (+) and (−) from (−). The stimulus appears to be transmitted by the diffusion of a volatile substance from one zygophore to another. A tentative explanation of the phenomena described is advanced, based on two postulated volatile hormones, each evolved by zygophores of one mating type only, stimulating growth in zygophores of its own mating type and retarding it in those of the opposite type. The results of these new investigations appear to dispose of the 'mitogenic ray' and 'accidental contact' theories of earlier workers.

## Visual Education

IN co-operation with Unesco, the Central Council for Health Education has produced the latest issue of its *Health Education Journal* as a symposium on visual education (13, No. 1). The contributors are drawn from many parts of the world and, besides members of the Council's own staff, include such distinguished people as "Fougasse" on propaganda posters and Walt Disney on the development of animated cartoons. The use of moving films in combating human and animal disease in Tanganyika is described by N. F. Spurr, while not the least valuable article is one by Dr. A. L. Knutson, of the United States Public Health Service, who suggests ways in which the effectiveness of visual material may be evaluated.

## Ultrasonic Testing of Concrete

The Road Research Laboratory deals with the non-destructive testing of concrete in its Technical Paper No. 34, entitled "Testing Concrete by an Ultrasonic Pulse Technique", by Dr. R. Jones and E. N. Gatfield (pp. 48 + 2 plates. London: H.M.S.O., 1955; 2s. 6d. net). Until recently, the only way in which the physical characteristics of concrete and the changes brought about by ageing and other causes could be determined was by tests to destruction carried out on specially prepared specimens. These tests, though useful, are not entirely satisfactory, and a method of measuring changes in the quality of concrete *in situ* by transmitting an ultrasonic pulse through concrete has been extensively investigated and developed at the Laboratory. The ultrasonic equipment described consists of two piezoelectric transducers placed on opposite faces of the concrete under test, and the pulses are timed electrically as they pass from one transducer to the other through the concrete. The time of transmission indicates the characteristics of the concrete and the presence of internal cracks. Any deterioration due to weakness or poor compaction can be detected. Examples are given of the practical applications of the method. The ultrasonic technique can also be used for testing road surfaces; this involves the use of reflexion, the sound pulses being reflected back by the lower surface of the concrete. The difficulty here, however, is that the method is only satisfactory when the underside of the concrete is relatively smooth. In practice, transducers having natural frequencies of 50–200 kc./s. are used because of the upper limit to the frequency imposed by the attenuation of the concrete. The repetition frequency of the pulses is 50/sec., and the accuracy of measurement of the time of propagation of a pulse of longitudinal vibrations between the two transducers is of the order of ½ per cent for concrete. Full details of the apparatus used and of the experimental technique are given in an appendix. Brief reference is made also to applications of the technique to materials other than concrete, for example, soil-cement, rocks, ceramics and wood.

## Catalogues of the Exhibits on Heat at the Science Museum, London

Two well-produced illustrated handbooks have been compiled by J. A. Chaldecott, of the Science Museum, London, giving detailed descriptions of the exhibits in the collection of heat and thermal instruments at the Museum. The exhibits are arranged in a number of groups, each dealing with one aspect of the subject, and these groups are further divided into sub-groups within which the exhibits are arranged so far as possible in chronological order. The first handbook, "Heat and Cold" (pp. 64 + 6 plates. London: H.M.S.O., 1954; 3s. net), covers thermal expansion, calorimetry, change of state and critical state, heat and heat transfer, refrigeration and low temperatures, and altogether 166 individual exhibits are listed. In addition, details are given of nine portraits of distinguished workers in the field of heat. The other handbook, "Temperature Measurement and Control" (pp. 65 + 4 plates. 1955; 3s. 6d. net), is limited in content to the various types of thermometers, pyrometers, thermostats and temperature recorders, and 153 exhibits are listed. A reference list of thermometers and temperature-recording instruments kept in the meteorology collection of the Museum is appended for completion. In accordance with the 1948 recommendations of the Ninth General Conference on Weights and Measures, 'Celsius' is used for the temperature scale previously known as 'Centigrade'. In both handbooks the catalogue entries consist of the substance of the descriptive labels attached to the various exhibits in the Museum. The details given are most informative, and should be of considerable value and interest to physicists and to those concerned with the history of science. Though modern apparatus is by no means excluded, the emphasis is naturally on the original and earliest forms of thermal instruments. The descriptions of these in most of the text-books is now often so inadequate or incorrect that authors and students would be well advised to use the handbooks, together with a visit to the Museum, for details of particular instruments. For the more serious student, the handbook also provides the reference to the article in which the apparatus or method was originally described or to the maker or designer of a particular item. Photographs of the exhibits and lantern slides may be purchased, and the latter can also be borrowed.

## Energy Expenditure in Man: Symposium in London

The Nutrition Society is arranging a symposium on "Energy Expenditure in Man", under the chairmanship of Prof. R. C. Garry, to be held at the National Institute for Medical Research, London, N.W.7, on October 15. Papers will be read on the following topics: the development of experimental methods for determining the energy expenditure of man (Prof. C. G. Douglas, Oxford); modern techniques for measuring energy expenditure (Mr. H. S. Wolff, London); the value of energy expenditure measurements in nutritional studies (Dr. O. G. Edholm, London); daily energy expenditure by man (Dr. R. Passmore, Edinburgh); energy expenditure and age (Dr. J. V. G. A. Durnin, Glasgow); energy expenditure in athletic activities (Mr. H. R. Noltie, Leeds). Further information can be obtained from the honorary programmes secretary of the Society, Dr. R. J. L. Allen, c/o Beecham Foods, Ltd., Brentford, Middlesex.

## The Story of Pharmacy: Exhibition in London

An exhibition on "The Story of Pharmacy" has been set up by the Wellcome Historical Medical Museum at the Wellcome Building, Euston Road, London, N.W.1, to coincide with the Sixteenth General Assembly of the International Pharmaceutical Federation, which is meeting in London during September 19–23. The exhibition will be opened by the president of the Federation, Sir Hugh Linstead, on September 19, following the presidential address with which he will open the Assembly. All the objects to be shown at the exhibition have been selected from the collections at the Wellcome Museum and cover the history of pharmacy and related subjects from the earliest times to the advent of antibiotics. The exhibition is sub-divided into the following periods: prehistory, Assyria, Babylonia and Ancient Egypt; Græco-Roman period; the medieval world; the sixteenth century; the seventeenth century; the eighteenth century; and the nineteenth and twentieth centuries. Many of the objects, books and manuscripts to be displayed are noteworthy not only for their historical and scientific value but also for their beauty as works of art. The exhibition will remain open to the public (admission free) for several months.

### Swiss Society for Natural Sciences: Annual Meeting

The 135th annual meeting of the Swiss Society for Natural Sciences will be held in Porrentruy, Pruntrut, during September 24–26. The general proceedings will open with an address by the president, Dr. E. Guéniat, director of the Normal Teaching College of Porrentruy, on the scientific work of Jules Thurmann (1804–55). Prof. R. L. Gautheret (Sorbonne, Paris) will speak on physiology and nutrition in tissue-culture. Other topics will be: Swiss researches in Central Africa (a programme of scientific films); finalism and physicism (a symposium under the chairmanship of Prof. F. Gonseth, of Zurich); calculating machines in the service of technique and science (Prof. E. Stiefel, of Zurich); and tracking down carriers of hereditary diseases (Prof. A. Franceschetti, of Geneva).

### Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: G. D. Badger (senior agricultural officer, Uganda), senior agricultural officer (superscale), Uganda; G. S. Cowley (senior agricultural officer, Kenya), assistant director of agriculture (field services), Kenya; G. S. Gollop (senior agricultural officer, Kenya), provincial agricultural officer, Kenya; P. L. Hotchin (agricultural officer, Mauritius), senior agricultural officer, Mauritius; A. E. Moss (assistant director of agriculture, Gold Coast), deputy director of agriculture, Gold Coast; E. J. Honore (conservator of forests, Kenya), deputy chief conservator of forests, Kenya; P. C. Lancaster (principal research officer, Federation of Nigeria), director of forestry research, Federation of Nigeria; D. G. B. Leakey (assistant conservator of forests, Kenya), conservator of forests, Kenya; K. R. M. MacDonald (conservator of forests, Northern Region, Nigeria), chief conservator of forests, Northern Region, Nigeria; R. M. Palmer (senior assistant conservator of forests, Sierra Leone), conservator of forests, Sierra Leone; R. V. H. Porter (assistant conservator of forests, Kenya), conservator of forests, Kenya; T. I. Rees (senior assistant conservator of forests, Western Region, Nigeria), conservator of forests, Western Region, Nigeria; R. Smeathers (deputy conservator of forests, Trinidad), conservator of forests, British Guiana; J. A. R. Bates, specialist officer chemist (agricultural), Federation of Nigeria; B. L. Batwell, agricultural officer, Northern Rhodesia; J. R. Simpson, chemist, Agricultural Department, Uganda; J. Walker, agronomist, Somaliland Protectorate; J. Jago, government chemist, Zanzibar; J. P. de C. Walsh, assistant conservator of forests, Northern Rhodesia; J. V. Huhta, mining geologist, Sierra Leone; D. J. Slater, geologist, Federation of Malaya; A. J. Warden, geologist, Somaliland Protectorate; R. Q. Craufurd, scientific officer, plant breeder, Sierra Leone; J. Thorsen, veterinary officer, Northern Region, Nigeria.

### Announcements

Mr. H. A. Sargeaunt, at present scientific adviser to the Army Council, has been appointed assistant to Dr. H. P. Robertson, of the United States, scientific adviser to General Gruenther, the Supreme Allied Commander, Europe. Mr. Sargeaunt will be succeeded as scientific adviser to the Army Council by Mr. Patrick Johnson, formerly director of studies at the R.A.F. College, Cranwell, and since 1952 dean of the Institute of Armament Studies, India.

Prof. J. Heyrovský, academician of the Czechoslovak Academy of Sciences Section of the Czechoslovak Academy of Science, Prague, has been elected president of the Polarographic Society in Great Britain (see *Nature* of January 1, p. 20). He hopes to deliver an inaugural address in the near future.

Edward Longstreth Medals of the Franklin Institute, Philadelphia, have been awarded to C. Waller, of Ilford, Ltd., and Dr. R. Berriman, of Kodak, Ltd., for their work on the development of photographic emulsions especially designed for the study of nuclear particles and events.

Mr. E. Ll. Harry, provincial director of the West Midland Province, National Agricultural Advisory Service, has been appointed director in Wales in succession to the late Mr. D. Walters Davies. Dr. D. H. Robinson, deputy provincial director for the West Midland Province, will succeed Mr. Harry in that area.

The British Oxygen Co., Ltd., has awarded the following three fellowships for postgraduate research: R. Clarkson (formerly of the University of Manchester), chemistry, at the University of Oxford; R. A. H. Pool, inorganic chemistry, at the University of Oxford; and D. I. Wilkinson, organic chemistry, at The Queen's University, Belfast.

The following appointments in the University of London have been announced: Mr. H. L. Elvin, director of the Department of Education of Unesco, to the University chair of education with special reference to education in tropical areas, tenable at the Institute of Education; Dr. A. H. M. Arnold, head of the Electronics Section of the Electricity Division of the National Physical Laboratory, to the University readership in electrical engineering tenable at King's College.

The Trustees of the Ciba Foundation for the Promotion of International Co-operation in Medical and Chemical Research are offering five awards, of an average value of £300 each, for the period 1955–56, for research relevant to basic problems of ageing. Entries will be judged by an international panel, and in making the awards preference will be given to younger workers. The work submitted should not have been published before July 31, 1955. Further particulars can be obtained from the Director and Secretary to the Executive Council of the Ciba Foundation, 41 Portland Place, London, W.1, to whom entries must be sent by February 10, 1956.

The Swiss Federal Institute of Technology, Zurich, will hold its centenary celebrations during October 17–23. A programme of lectures and excursions, primarily intended for the old students' association, will be held during October 17–20.

Erratum. In the leading article in *Nature* of August 27, p. 365, par. 1, it is stated that "earlier hopes that alginates would serve as a technically and economically desirable source of chemicals have been disappointed"; this should read "earlier hopes that seaweeds would serve as a . . . source of chemicals other than alginates. . . ."

# COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION, AUSTRALIA

## REPORT FOR THE YEAR 1953–54

THE sixth annual report of the Commonwealth Scientific and Industrial Research Organization, Australia, covering the year ended June 30, 1954*, again stresses the difficulties in attracting first-class men to research careers in science. The position became markedly worse during the year and is regarded as alarming. At the beginning of the year there were vacancies for 112 research officers, for which the minimum requirement is a good honours degree, and at the end of the year there were still 109 such vacancies. Recruitment of technical officers, however, was satisfactory; but concerted efforts to recruit scientific officers from overseas, mainly the United Kingdom, had most disappointing results, and the Executive believes that it is a matter of great urgency that the prospects for specialists and highly qualified professional scientific workers in Australia, both in public and private employment, should be greatly improved. Expenditure for the year was £4,861,873, of which £3,615,121 was on normal research activities and £98,271 as grants to bodies such as the Commonwealth Agricultural Bureaux. £569,038 was expended from the Wool Research Trust Account (for which £390,807 was received from the Department of Commerce and Agriculture), £372,399 from the Wool Industry Fund and £205,081 on sundry projects for which grants were received from outside bodies.

In the Division of Soils, the group concerned with soil mineralogy is developing into a new section, and a small new unit for field-work has been set up at the Irrigation Research Station, Griffith, N.S.W. A new soils laboratory has been established at Canberra, and a Soil Survey Co-ordination Committee in Victoria, while a further such Committee is being organized in Western Australia, where the soil survey of the Swan valley is complete. In the low-fertility lands of the Tintinara district of upper south-east South Australia a soil map and report on three hundred square miles have been completed and also field-work on four hundred and fifty square miles of similar lands in the Tatiara district. In soil chemistry an investigation into the ion-exchange relations of various cation-dominant soils has been completed, and in further experimental work on the availability of manganese and other heavy elements an improved method has been devised for the extraction of divalent manganese from soils, based on the use of salts of ethylenediamine tetraacetic acid. Typical Western Australian lateritic profiles have been examined spectrographically, and possible correlations in the concentrations of copper, gallium, magnesium, manganese, molybdenum and vanadium in samples of Urrbrae loam are being examined. A simple method has been devised for extracting the exchangeable cations in calcareous soils, and studies of the interactions of sodium, potassium, calcium and magnesium indicate that calcium has a marked effect on the determination of magnesium in a flame spectrophotometer. Further work is being carried out on the effect of initial water content on the water stability of soil aggregates, and studies have been made of the virulence and incursion strains of *Rhizobium trifolii*, while attempts are being made to isolate proteins and saccharides from soil humus by electrophoresis.

The Division of Plant Industry has considerably expanded the work in agrostology and agronomy in Queensland, and good progress is reported in work which is to open up the coastal lowlands of south-eastern Queensland for intensive pasture development. At Canberra evidence was obtained that clovers may compete with grasses for the nitrogen which they themselves assimilate, and that grass development may suffer from competition for nitrogen by the associated clover. For full efficiency of assimilation of nitrogen by legumes, it seems necessary to utilize the nitrogen they incorporate in the soil, either as hay removed from the area or by cropping. In genetics a programme of inter-specific hybridization in the Australian grasses is planned, while inoculation experiments with *Phytophthora infestans* on *Acacia*, *Cassia* and *Erythrina* spp. showed that the parasite penetrates the leaf epidermis but is checked by a severe 'defence' reaction which is similar to the lesion reaction known in cereals infested with rusts and some other parasites. Systemic absorption of streptomycin by potato and tomato plants led to a change in the reaction of the host to infection by *Phytophthora infestans*, the causal organism of late blight.

Most of the work at Hobart on the physiology of apples in relation to storage disorders is concerned with the effect of manurial treatment on cell size and physiology in relation to keeping quality. Extensive agronomic and breeding studies on safflower (*Carthamus tinctorius* L.) were continued, and also breeding for resistance to tobacco mosaic. Resistance in the variety Ambalena is associated with slow multiplication and spread of the virus followed by inactivation within the plant. A method has been developed for the determination of molybdenum in soils, and considerable progress was made in the study of the effects of lime on the nodulation of clover. Factors affecting the response to fertilizers were being examined, and a study of the effects of deficiencies of essential elements on the amino-acid composition of plants was continued. Contrary to the established view, glutamine has proved superior to asparagine as a source of nitrogen for the growth of isolated embryos of *Medicago tribuloides*, and quantitative relations between glutamine and asparagine were being established for a range of leguminous and non-leguminous embryos. Surveys to classify and map plant communities were proceeding in the Southern Tablelands, Macquarie and New England regions of New South Wales, and in the rain-forest regions of Queensland and northern New South Wales. An investigation was initiated on the biochemistry of morphogenesis in plants, particularly the induction mechanisms underlying the formation of a new meristem during regeneration and its subsequent mode of differentiation. Studies on root concentration and chloride content in native pastures at Deniliquin, New South Wales, indicated that the growth of grasses in the *Atriplex vesicaria* community was limited by 0·23–0·43 per cent of sodium chloride in the 3–9 in. depth. A pot trial using grey clay soil and sandy loam soil from areas which had been under native pasture, and from other areas which had been under fertilized irrigated pasture for six years, showed that 'Krilium', while greatly improving the aggregate stability of both loam and clay soils and reducing the mass shrinkage of the latter, depressed yields on clay soils and increased them slightly on loam soils, the effect being most marked on soils which had not been irrigated. The ecological survey of the coastal lowlands of south-eastern Queensland continued, and work was commenced on the genetical aspects of selected pasture legumes and grasses relevant to their improvement and adaptation to coastal and sub-coastal Queensland.

---

* Commonwealth of Australia. Commonwealth Scientific and Industrial Research Organization. Sixth Annual Report for the Year ending 30th June, 1954 (1953–54). Pp. vi+372. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1954.)

An important part of the work of the Irrigation Research Station at Merbein, Victoria, deals with the reclamation of deteriorated horticultural lands which have not responded to tile drainage. Of the horticultural crops, vines for dried fruit are the most important, and investigation of some of the components of sultana-yield continued and also of manurial and cultural practices. Flowering and fruiting in citrus have been further investigated and the programme of tomato breeding for field and glasshouse continued. The work of the Irrigation Research Station at Griffith, N.S.W., has been designed to lay the basis for an effective counter to water-logging and salting and to develop more efficient techniques in the use of irrigation water.

The Animal Genetics Section of the Division of Animal Health and Production, which was established in 1952 with the co-operation of the University of Sydney, besides investigating the application of genetics to animal breeding, endeavours to introduce university students interested in genetics to the techniques and concepts of quantitative inheritance. It has been found that, whereas heritability of response to a simple antibody is high, heritability of response to a complex one is low. Following the demonstration by the Division of Biochemistry and General Nutrition that areas in South Australia abandoned as useless for agriculture can be transformed for efficient production when trace deficiencies of zinc and copper have been rectified, complementary work on pasture improvement has shown that vast areas of Australia, particularly in regions of low rainfall, can also be rendered more productive after trace-element adjustments have been made. An investigation on chronic fluorosis in sheep, now virtually complete, has proved that waters containing 10 p.p.m. fluorine are harmful to grazing stock and that the untoward effects of chrome fluorosis on the general well-being of the sheep arise primarily from the teeth lesions. A main activity of the Division's work on sheep during the year has related to the effects of molybdenum on the copper metabolism of the sheep and to the effects of imposing considerable doses of sulphate, etc., on relatively high intakes of molybdenum. Administration of a supplement equivalent to 1 mgm. cobalt/day as a drench once a week completely protected sheep from '*Phalaris* stagger', a fatal malady occurring spasmodically among sheep grazing essentially on the perennial grass *Phalaris tuberosa*. Research on the biological activity of complex ions was continued by the Division in collaboration with the University of Sydney. Further therapeutic trials were carried out with antibiotics against staphylococcal mastitis in dairy cattle and studies were being made to determine the factors responsible for outbreaks of hæmonchosis. In an investigation to discover a chemical method of assessing the resistance of strains of ticks to acaricides, it was found that when DDT is dissolved in normal primary alcohols, butyl, amyl and hexyl alcohols gave the greatest penetration.

The work of the Division of Entomology continued to be increasingly concerned with the more fundamental aspects of entomology. In current research on the cattle tick, the emphasis has shifted to the strategic timing of dipping, so as to ensure that from time to time all the ticks in a given area are exposed to dipping, and not merely those which happen to infest the animals at a given moment, and to the 'spelling' of pastures, with a similar object. In Western Australia more attention was being given to ecological studies on the earth mite and lucerne flea than to chemical treatment, and promising results were obtained in the campaign in Sydney for eradicating the Argentine ant. A study was commenced of the ecology and pathology of the black beetle. Using the sheep blowfly (*Lucilia cuprina*) as experimental animal, work was continued on the way populations accommodate themselves to external stresses. The study of the effects of airtight storage conditions on the grain weevil, *Calandria granaria* L., has shown that all stages are killed by the reduction in oxygen due to the respiration of the insects and the grain.

The work of the Wildlife Survey Section on myxomatosis has included regional surveys to assess the seasonal performance of the disease and to collect information on local variations, intensive investigations into the ecology and behaviour of insect vectors, and work on variant strains of the virus. A field-station for the intensive investigation of the kangaroo and euro problem has been established in north-western Australia. The Australian Mainland Survey Unit of the Land Research and Regional Survey Unit concentrated its effort in the Leichhardt-Gilbert area. The Section has also made a survey of Nauru Island and conducted some agricultural research in North Australia, including problems of dryland agriculture and a programme of testing plant introductions.

The work of the Division of Fisheries was again limited to coastal waters, because only two small research vessels were available. A detailed histological study of the reproductive cycle of the western subspecies of the Australian salmon continued, and a study of the relative abundance of estuarine species in Lake Macquarie, New South Wales, and their interaction was commenced in conjunction with environmental studies on the hydrology, microbiology and planktology of the Lake. An extensive survey in February 1954 of the south-western Tasman Sea demonstrated the path of the east Australian current in this area and the continuity between southern Tasmanian waters and the deep Tasman Sea waters below the 12° C. isotherm.

Despite progress in the investigations on beef, methods for the elimination of 'drip' from frozen and thawed beef are unlikely to be found in the near future. The precise water requirements of a number of strains of bacteria causing spoilage or food poisoning have been defined, and the amounts of water in various foods which will permit the growth of these organisms can now be predicted. A dip of sodium *o*-phenylphenoxide has proved the most effective method of reducing the green mould which is the chief cause of wastage in oranges grown in the natural rainfall districts. Using the maturometer and experimental techniques developed by the Division of Food Preservation and Transport, it has been found that the general developmental pattern of varieties of peas tested at Geneva, New York, agrees with that determined in Australia. Respiration studies have led to a hypothesis connecting the energy liberated by respiration with the energy-requiring processes in the cell, and this hypothesis has been used to interpret the sudden rise in respiration associated with the ripening of fruits. Attempts are being made to find improved methods of storage for apples.

The Division of Forest Products continued the study of the anatomy of tubers occurring in the south-west Pacific area and completed a detailed study of the influence of chip shape on the delignification of *E. regnans* wood by sodium sulphide and by sodium hydroxide. Studies were commenced on the rheological properties of hand sheets made from typical pulps of different qualities. A pressure membrane apparatus has been designed to study sorption of water by wood at relative humidities above 98 per cent; a quantitative comparison of creep at constant stress with stress relaxation at constant deformation showed that wood behaves approximately as a linear viscoelastic body, but attempts to establish an empirical formula for the relation between impact strength and moisture content were unsuccessful. Studies were commenced on the influence of physical conditions on vapour movement in hardwoods.

The work of the Division of Building Research continued on similar lines to that of the previous year. Information obtained from the study of the mechanism of the failure of concrete under load has led to a tentative theory of rupture of concrete in which the criterion of failure is a function of the shear-strain energy per unit volume and the volumetric expansion. Thermal and X-ray examination of synthetic gypsum indicated that the conditions of precipitation influence the behaviour during dehydration. In the Wool Textile Research Laboratory at Melbourne, work on the fundamental properties of the proteins of the wool fibre has been intensified, with particular emphasis on methods for separating and analysing the protein entities present. Further research in weaving and dyeing was commenced at the Geelong laboratory, while work on the physical properties of the wool fibre and assemblies of wool fibres continued at the Sydney laboratory. The Plant Fibres Section completed mill-scale trials on the so-called aerated retting of flax, and a comprehensive investigation of the effect of atmospheric temperature and humidity on the performance of various fibres during spinning; it also continued basic studies on flax-retting bacteria as well as its study of the treatment of flax and other fibres with sodium hydroxide.

The Division of Industrial Chemistry commenced a programme of basic research into the properties of uranium di- and tri-chlorides. Satisfactory methods have been evolved for the production of commercially pure thorium nitrate, and studies on the electro-reduction of hexavalent chromium solutions have shown that the hydrogen chromate ion is much more easily reduced than the normal chromate ion and plays an important part as an intermediate product. A detailed study of the phototropic darkening of synthetic titanium dioxides when contaminated with iron oxide has shown that chromium, nickel and copper also produce a phototropic effect and that, although some of the rutile modification of titanium oxide (and also moisture) must be present, the most intense coloration, with iron, develops for the smallest conversion of a pure anatase modification to the rutile form. Investigations of the factors which, by causing mechanical stresses, decrease the life of the linings of rotary cement kilns continued, and an extensive series of measurements of the rates of organic reactions at pressures up to 15,000 atmospheres has shown that those reactions which produce ions from neutral molecules are assisted by pressure, whereas the converse reactions are suppressed. A new extraction process using solvents has been devised and demonstrated on the separation of alkaloids, and very promising results have been obtained in small-scale out-of-doors tests of the use of thin films of long-chain alcohols to retard the evaporation of water.

Work has also continued on the structure of crystalline and non-crystalline proteins, on the chemical physics of the solid state, the determination of molecular structure by X-ray diffraction and electron diffraction methods, and on the improvement of experimental techniques and development of new instruments, including a mass spectrometer, an electron microdiffraction camera, a microtome and an atomic absorption spectrophotometer. In organic chemistry, work continued on the pyrrolizidine bases responsible for liver damage in stock, and structural studies of the three minor bases of *Heliotropium europaeum* and an investigation of *Lupinus pilosus* were completed. Further work was done on increasing the unsaturation of olefinic substances with the view of converting low-grade non-drying oils into more valuable materials with drying properties, and the study of the phenol-formaldehyde with *o*-6-xylenol and excess alkali showed that the reaction is complex with regard to the concentration of xylenol, formaldehyde and hydroxyl ion. In chemical engineering most of the resources have been directed to the study of the techniques and reactions in the gasification of low-rank coals.

Further work was done on the magnetic separation of chromite from ilmenite, and a study was being made of the ignition and combustion characteristics of Australian coals with particular reference to their evaluation for combustion; the mechanism and rate of formation of methane in pressure gasification were being studied to provide a better understanding of the Lurgi gasification process, and the effect of pressures up to fifty atmospheres on the rate of the primary steam-carbon reaction was also being investigated. In physical metallurgy the titanium project has been extended to include the deformation and mechanical properties of titanium and its alloys at both normal and high temperatures, and the study of the creep of lead and its alloys continued. The Division of Tribophysics continued its work on the same general lines as in the previous year, including studies of the adsorption of long-chain organic compounds on solids of various types, of the mechanical properties and composition of films of long-chain compounds, and of solutions containing metallic ions. Measurements of energy stored in deformed nickel were continued, and studies of the effects of antioxidants on the decomposition of benzoyl peroxide indicated that free radicals are not involved.

The maintenance of Commonwealth standards of measurement is shared by the Divisions of Metrology, Physics and Electrotechnology, which comprise the National Standards Laboratory. The work on standards of length and their international comparison continued, and another important piece of work by the Division of Metrology was a very accurate determination of changes in density of strained material on annealing. The principles and practice of vibration and shock isolation were also investigated; to increase the precision of maintenance of the International Temperature Scale, the Division of Physics constructed new apparatus for the primary fixed points defined by the boiling points of water and sulphur and was constructing a precision manometer for measuring the controlled pressures at which boiling occurs. A new method has been devised for the measurement and control of humidity, using a small ionic crystal as detector. Particular attention was given to the thermal and electrical conductivities of solids at very low temperatures. In the Division of Electrotechnology the special resistor for building up from one to a hundred ohms was completed and tested, and work continued on the relation between the chemical and physical structure of organic and some complex inorganic compounds and their dielectric properties. Besides dielectric measurements on a wide range of urea occlusion compounds, a portable bridge was made for measuring the temperature and salinity of estuarine waters to a depth of sixty feet.

The Division of Radiophysics continued its fundamental work in rain and cloud physics and in radioastronomy, and has also investigated a proposed method of navigating long-range aircraft by measuring the distance from the terminal points of the path. Ionosphere measurements were concentrated on studies of the anomalous $F2$ region, the conductivity of the ionosphere, and storm morphology and ionization movements in the ionosphere. In atmospheric physics the work included the study of the dry-monsoonal circulation which predominates over the west and north-west of Australia; an intensive investigation of the transfer of heat and water vapour from the ground surface to the atmosphere, of the frictional influence of the ground on the wind and of the prevention of frost in citrus; and a scientific study of the natural processes which give rise to cloud and rain and of possible methods of stimulating rainfall by artificial means, in which powerful microwave radar techniques have been of great assistance. Observations of radio-frequency radiation from cosmic sources and from the sun were continued, and a method was devised of obtaining an effective pencil-beam aerial of high aperture and angular discrimination at relatively low cost. Work on the analysis of rainfall records was concluded, and although the electronic computer could not be completed in accordance with the original design specification, it has been operated with reasonable efficiency on a wide range of problems.

# SCIENTIFIC RESEARCH AND MAN-POWER IN THE UNITED STATES

IN addressing the sixth annual conference on industrial research at Columbia University, New York, Dr. A. T. Waterman, director of the National Science Foundation, outlined the survey of scientific research and development in the United States which is being conducted by the National Science Foundation. For the fiscal year beginning July 1, 1955, the United States expenditure on research and development is expected to exceed 4,500 million dollars, 2,400 million of which will be borne by the Federal Government.

Dr. Waterman anticipates that a fourth volume of the Foundation's continuing study, "Federal Funds for Science", covering the years 1954–56, would be published shortly. He notes that 98 per cent of the total funds are accounted for by seven of the twenty departments or agencies of the Federal Government which reported funds for scientific research and development, and that, of these twenty, only the National Science Foundation and the Smithsonian Institution have used all their research funds for basic investigations. The Foundation has also undertaken a historical summary of Federal funds for science during 1900–54 and an analysis of the Federal financing of higher education. One of the agricultural experiment stations was expected to be complete late this year. A history of the activities of the Federal Government in science during 1789–1940, by Dr. H. Dupree, was reported as being almost complete, and the most significant data on scientific man-power in the Federal Government are being compiled in a separate monograph. A study of the financial support of graduate students (which covered 152,000 of the 225,000 graduate students of 1954) is nearing completion. Twenty-five per cent of the students covered held teaching or research assistantships or fellowships in April 1954, and 20 per cent were enrolled in the natural sciences.

A preliminary report on foundation expenditures for scientific research, covering seventy-seven foundations with assets totalling 3,000 million dollars and an income of 166 million dollars, of which about 16 per cent went for scientific research and development, indicates that only forty-three of the foundations gave support to scientific research at all and that this support is decreasing in comparison with other fields of study, while there is a trend from the support of basic research towards applied research and development. Industry conducts about 65 per cent of the national industrial research effort and finances 42 per cent of this total; but the industrial survey is not yet complete, and although a preliminary survey has been made of research being conducted by trade associations, studies of the economic implications of research are still in the planning stage. A preliminary draft has been received of a report on shortages of scientific and engineering personnel in industrial research, and studies are being sponsored of three problems: the loss of talent through educational 'drop-out'; estimating the supply of technical and professional man-power for 1965; and methods for determining demand and supply of technical personnel. It is hoped to present the findings of these studies in a series of general reports.

# PLASTICITY OF MATERIALS

## SYMPOSIUM IN LONDON

A TWO-DAY symposium on plasticity, arranged by the Armament Research and Development Establishment (Ministry of Supply), Fort Halstead, with the co-operation of representatives from universities, establishments of the Department of Scientific and Industrial Research, and industry, was held in London at the Assembly Hall of the Royal Empire Society during July 4–5. The director of the Armament Research and Development Establishment, Mr. Ewen M'Ewen, opened the symposium with an address of welcome to about eighty delegates, in which he reminded his audience that the subject of plasticity was forged in the genius of Saint-Venant; he stressed the continuing progress in the subject, particularly within recent years.

In four sessions of the symposium, eleven papers were presented and discussed. The papers taken as a whole represented a fair cross-section of the general nature of the work on plasticity proceeding in various centres not only in Great Britain but also elsewhere. Thus typical problems with a bias towards either engineering, physics or mathematics were described. The wealth of variety in the problems currently receiving attention was apparent, and this situation should increasingly attract research workers to this field. An adequate summary of the papers would perforce either be very lengthy or assume that the reader had a detailed knowledge over a wide horizon in the general field of plasticity. As most of the material presented is either already available or will become available in due course, an account will be given in this article only of the discussion that followed the papers.

After Prof. D. G. Christopherson had introduced the discussion, Prof. H. Ford directed attention to the practical importance of the Bauschinger effect and to the development of anisotropy in continued plastic deformation as, for example, in cold rolling; he made a plea for the theoretical study of the effects of departure from the assumptions of isotropic plasticity. Dr. J. F. W. Bishop replied that Prof. R. Hill had formulated a theory of anisotropic plasticity. The real obstacle to progress lies in the intrinsically difficult nature of the governing equations, and the incorporation of anisotropic effects in the theory does not pose the major problem. Dr. Bishop emphasized the importance of studying the inter-relation of crystalline and macroscopic plastic properties of metals in order to develop further the physical basis for the mathematical theory of plasticity. Otherwise, this theory will necessarily involve at least some features at a phenomenological level.

Dr. J. W. Macoll said that he has observed a recent trend towards a preference for the Tresca yield criterion, as opposed to that of von Mises, for a material under combined stress, in the theoretical treatment of problems. This is due largely to reasons of mathematical simplicity. He was glad to note the remarks of Dr. Bishop justifying, on the basis of the physics of single metal crystals, the occurrence of singular points on the yield surface. Singular points are, of course, an essential feature of the Tresca yield criterion. Dr. Macoll thought that more attention to the physical basis of the mathematical theory of plasticity, previously emphasized by Dr. Bishop, might not only point the way to, but would also justify, simpler mathematical approaches in macroscopic plasticity. Prof. Christopherson then raised the general question of the computation of bounds to the solution of problems. In reply, Mr. A. P. Green said that the methods available are not of sufficient generality. He also expressed the opinion that the relationship between the mathematician's ideal rigid-plastic material and actual metals requires further careful exploration. In respect of one of Dr. Macoll's remarks he cautioned against the facile assumption that the analytical solution of a problem is always moderately insensitive to changes in the yield condition and plastic potential, and counter-examples were recalled.

Mr. H. G. Hopkins returned to Prof. Christopherson's question, and said that the fundamental trouble is that a general method of construction of sequences of approximate solutions which converges to the true solution of a problem in plasticity is not available at the present time. In this respect there is a sharp contrast to problems of elasticity, where such methods are available and are much used in technical applications. Prof. Christopherson added that one difficulty is to decide *a priori* the extent of plastic regions. He went on to ask about general theorems in visco-elasticity. Mr. D. R. Bland said that any general theorems involving potential energy would be applicable to dynamic elasticity, and that there are few theorems known in that field. Therefore, it seems that such theorems in visco-elasticity will concern the dissipation function as well as the potential function. Dr. H. Kolsky made a plea for a greater volume of experimental work on visco-elastic solids to provide more adequate data for the theoretical treatment of problems in this field. Prof. Christopherson was impressed by the apparent simplicity of the theoretical models used to simulate the actual mechanical behaviour of visco-elastic solids. Dr. Kolsky replied that the degree of agreement is not always completely satisfactory, and this is why more accurate experimental data are needed. Mr. Bland observed that recent work of his indicates that the theoretical analysis of certain visco-elastic problems can be based directly on the complex modulus versus frequency relation instead of proceeding via the stress–strain relations.

H. G. HOPKINS

---

# BRAZILIAN SOCIETY FOR THE PROGRESS OF SCIENCE

## ANNUAL MEETING

THE seventh annual meeting of the Brazilian Society for the Progress of Science (Sociedade Brasileira para o Progresso da Ciência) was held during July 4–9 at the Engineering School in Recife, Pernambuco. The president for the meeting was Dr. Anísio Teixeira, director of the National Institute of Pedagogical Studies of the Brazilian Ministry of Education, and the inaugural lecture on "Some Aspects of the Development of Mathematics in Brazil" was delivered by Dr. Leopoldo Nachbin.

The chief guest was Prof. Bernardo Houssay, of Argentina, who delivered a lecture on "General Considerations on Research and its Role in Latin America". Other foreign guests included Dr. L. Leloir, also from Argentina, and the science officer of the British Council in Brazil, F. M. Beatty, who lectured on British scientific travellers in the north and north-east of Brazil. Some 136 scientists and others attended this year's meeting. The programme included about 160 papers, mainly on biological subjects. Local scientists contributed especially to the sessions on nutrition in the north-east of Brazil and on mycology. In addition, special symposia were held on spot tests, experimental psychology and education, enzyme activity and, of more general interest, on "Science and Humanism". A memorial lecture on Einstein was given by Prof. Mario Schenberg, of the University of São Paulo. The principal functions were attended by Dr. Gilberto Freire, the well-known Brazilian sociologist.

The meeting was pleased to hear the message, read before one of the lectures, bearing fraternal greetings from the British Association for the Advancement of Science. The next meeting is planned to take place in Ouro Preto (Minas Gerais) in July 1956.

---

# PROBLEM OF REWARDING RESPONSIBILITY

IN the past twelve months much has been heard of the skill differential between craftsmen and labourers; for example, engineering tradesmen and labourers; building tradesmen and labourers; and, more recently, footplatemen and other railway workers. Less easy to define, though just as pertinent a problem, is the wage relationship in many manufacturing industries between various categories of unskilled or semi-skilled process workers. There is also the problem of wage relations between workpeople paid by results and those paid by time-rates for whom no opportunity to earn incentive bonus has been provided. There are, of course, many other differentials, such as those based on sex and age, time and place. Differentials are sometimes as potent a source of friction in industrial relations as the question of the wage-level itself; their effects have been elaborated by G. R. Moxon and H. J. Perkin (*Personnel Management*, 37, No. 332; June 1955).

Before 1914 the rates of pay for unskilled workers were 50–65 per cent of those for apprenticed craftsmen; to-day they are nearer 80 per cent. The pace at which differentials have narrowed has accelerated since the War. The trend is accounted for by the bargaining strength of trade unions, particularly among the less skilled, in conditions of labour shortage and, latterly, very full employment; by the social conscience of what constitutes a fair minimum time-rate of wages; by social insurance and by acceptance of the wider application of the principles and practice of collective bargaining, conciliation and arbitration. The practice of giving the same general wage increase to all grades is the most obvious post-war feature of the drive towards a more egalitarian distribution of the national product.

Yet, difficult as is this problem of differentials, it is doubtful whether it can compete in complexity, obscurity or long-term significance for the well-being of industry, with the problem raised by the narrowing of another group of differentials, those based on responsibility. It is substantially true that the premium paid to those who direct, organize and supervise the work of others has dwindled as fast as the premium paid to skill.

This is not a problem peculiar to industry; it is found wherever responsibility is exercised: in the Civil Service, banks, local government and, probably, most professions, and is part of the general trend towards greater equality between traditionally middle-class and working-class occupations. Indeed, the problem may well be more acute outside industry than it is inside, where the employer can more readily assess and determine fair differentials to be paid for various positions of responsibility.

In their article, Moxon and Perkin explore the social and economic setting in which the problem has come about, and discuss some of the factors which give it its peculiarly intractable shape.

Their discussion is chiefly concerned with middle and junior management—overseers, foremen, departmental managers and technical assistants, whose training demands that they should exercise leadership, organize work, use and keep abreast of modern management, methods and controls, but whose living standards are being overtaken from below.

The problem is obscure because information about salaries is not available except under privilege. The problem is complex because it is by no means confined to the comparative size of the pay-packet. That it also includes questions of status, privilege, job security and pension rights—in all of which there has been a narrowing of the traditionally held differential—is obvious.

The background to the problem is formed by the social revolution of the past half-century. Fifty years ago society was a tall pyramid with many steps. A small group at the top was very rich, and a somewhat larger group very comfortably off: together, this top 1 per cent of income earners received nearly 30 per cent of the nation's income. At the bottom about a third of working-class families lived below the poverty line.

Fifty years of revolutionary reform have changed all that. Graduated taxation has levelled down the incomes, and, to a smaller extent, the capital of the rich. At the same time, social services and the remarkably rapid rise of the lower-paid worker have practically abolished poverty.

This means that the great majority of family incomes fall, after tax, within a narrow range of annual income—say, from £300 to £2,000. There is thus much room for differential awards. While the real earnings of almost all manual workers have risen (though skilled and adult male earnings less than unskilled, women's and juveniles'), salaries in real terms have in most cases been reduced.

At the same time, alongside the growth of the Welfare State, the trend towards greater equality of security and amenity has been reinforced by developments within the factory itself. Shorter hours, the five-day week, paid and longer holidays, canteen facilities, and the growing implementation of pension schemes, are extending to the manual worker a share of the privileges once exclusive to staff.

This measure of equality greatly aggravates the problem of rewarding responsibility. In many cases, middle and junior managers know that at least some of the workers they supervise enjoy a standard of living higher than their own.

The paradox is due to arbitrary differences in family circumstances, operating within a smaller net income range. First, the number of earners in the family, especially since the earnings of women and juveniles have increased, can make a significant difference. In general, the higher the status, the less likely is it that wife or children will contribute to the family budget.

Secondly, in spite of family allowance, tax reliefs and social services, commitments vary disproportionately from family to family. It is traditional for the salary earner to maintain standards of dress and spending appropriate to his status. His expenditure on other commitments, notably housing and possibly education, will be greater than the wage-earner's.

The problem of differentials in industry is substantially the same problem as that faced by society as a whole: how to share out inadequate resources between the various claimants. More specifically, it is a problem of two competing demands: the demand for fair shares and the demand for incentives for skill, initiative, ingenuity and responsibility.

To such problems there is no perfect solution. Any system of rewards must of necessity be a compromise—a reconciliation of incompatible claims. The compromise should provide a reasonably satisfactory reward for those who, inside and outside industry, carry the responsibility for upholding and extending our standards of life. This problem of rewards for responsibility is less critical and less explosive than that of differentials due to skill. The skill differential compels attention because its holders are organized and can use the force of a pressure group to publicize their grievances and gain their ends. No such relief is open to responsibility-holders.

Nor can they hope for a reversal of the social revolution which has aggravated the narrowing of their differentials. It is most improbable that there will be any return to the inequalities of pre-war days. For the narrowing of differentials there is no remedy but acceptance.

There are a number of factors helping to predispose responsibility-holders to accept a reasonable narrowing of differentials. First, the rewards of responsibility are not limited to material benefits, in cash or in kind. There are satisfactions to be gained from the exercise of responsibility itself: from a sense of doing a worth-while job. The Americans, but not the British, have inculcated that feeling into their industrial management at all levels.

Secondly, differences in monetary reward matter less once basic provision is secured for the major needs of life. The hardships experienced by some salary earners are, on the long view, comparative only, and take on an unreal appearance when set beside the poverty the social revolution set out to cure.

Thirdly, many of the responsibility-holders of to-day have risen, often via State-aided education, from lower down the social scale. They are less conscious of a traditional standard of living that they must maintain.

If the narrowing continues, what are the dangers which may result from it? There are two which are of real concern. One is that discontent may develop to the point where recruitment to positions of responsibility falls off and shortages occur; this appears to be the case with science teachers and with dentists. The other is that discontent will sap initiative and result in an immersion in unprogressive routine. Either, if it became widespread in industrial management, might make all the difference between a rising rate of productivity and a falling one.

The great enemy of all differentials is inflation. The pay-packet of the wage earner, especially the less skilled, has on the whole kept ahead of prices. Inflation seems to have become an instrument for re-allocating the national income in favour of those with the biggest bargaining power. Worse than its effect on the immediate purchasing power of salaries is its effect on savings and pension funds.

A stabilization of prices is extremely desirable; but it demands a self-restraint on the part of organized labour on which it would be unrealistic to rely. Many firms are already countering the narrowing responsibility differential by reviewing and re-assessing staff salaries whenever new wage settlements are made. It would be an act of prudence and justice if all followed the lead of the best. Though the problem has not reached the proportions of a crisis, no one can view with equanimity any further narrowing of the differential based on responsibility.

There are no quick solutions to the problem of rewarding responsibility. It is a matter for patient, long-term bargaining and readjustment.

---

# ATMOSPHERIC POLLEN

H. A. HYDE (*Proc. Linn. Soc.*, 165, 2, 107; 1955) has contributed new observations on the frequency of occurrence of pollen in the atmosphere which seem likely to be of interest to other investigators, including students of floral biology and quaternary botany, plant breeders, and members of the medical profession who are concerned with the problems of pollen allergy. The gravity slide method was used in making this pollen census. In the course of some ten years work, and making use of twelve different collecting stations, it has been possible to determine about 90 per cent of all the grains on the slides and to assign these to one or other of sixty-five different types.

The principal pollen types, listed in the order of their numerical importance, begin with the Gramineae with 48·3 per cent, followed by *Ulmus* with 11·6 per cent, *Quercus* 8·2 per cent, and so on down to *Ranunculus* with 0·41 per cent, and the sedges with 0·22 per cent. Variations in the pollen catch and in the preponderance of the different types from year to year in relation to weather conditions are considered and some interesting conclusions drawn. These are but indications of the several records presented and discussed.

On the subject of hay-fever, the author writes: "No kind of pollen is likely to evoke symptoms in a significant number of people unless it is formed and liberated in large quantities and is buoyant (so becoming and remaining airborne) and unless the source plant is widely and abundantly distributed. The results of the Cardiff pollen census, when considered in the light of this principle, show that the chief hay-fever plants of Great Britain are relatively few in number, viz., the grasses considered as a single group (since all kinds of grass pollen are generally assumed to be similarly antigenic), certain trees, viz., the oaks, ash, the elms and plane (notably in London), and certain herbs, viz., the plantains, docks and sorrels, and possibly common nettle. It is necessary before forming a diagnosis on a particular patient's hay-fever to be able to show that his symptoms coincided with or at least fell within the period during which he was actually inhaling the pollen concerned. For this purpose reference to the frequency diagrams is essential."

# GROWTH AND TITRATION OF THE VIRUSES OF FOOT-AND-MOUTH DISEASE AND VESICULAR STOMATITIS IN KIDNEY MONOLAYER TISSUE CULTURES

By R. F. SELLERS

Research Institute (Animal Virus Diseases), Pirbright, Surrey

AN accurate method of virus titration has been developed by Dulbecco. The method involves the counting of plaques produced by the destructive action of the virus on susceptible cells grown as a monolayer in tissue culture, and has been applied to the titration of the virus of equine encephalomyelitis, Western type (*WEE*), on chick embryo monolayers[1] and of poliomyelitis virus on monkey kidney monolayers[2]. Recently, my observation that the virus of vesicular stomatitis is cytopathogenic in tissue culture has led to the titration of this virus by the production of plaques on chick embryo monolayers and on ox embryo kidney monolayers. A necessary condition for the successful application of this technique is that the virus should multiply in the cells and produce destructive changes[3]. Since the virus of foot-and-mouth disease causes lesions in the infected animal similar to those caused by the virus of vesicular stomatitis, it was decided to investigate and compare the multiplication and destructive action of the two viruses in monolayer tissue cultures grown from kidneys of susceptible animals, and in particular to see if the accurate method of plaque counting could be applied to the titration of the virus of foot-and-mouth disease.

The method of preparation of the tissue cultures followed closely that described by Dulbecco and Vogt[2], including the solutions used. Kidneys of ox embryo, calves and pigs were obtained fresh from the abattoir. The capsule was removed and the cortex cut into small pieces, washed in warm phosphate-buffered saline, *p*H 7·5, and digested in 0·3 per cent trypsin in phosphate-buffered saline. The cell clusters thus obtained were washed three times in phosphate-buffered saline, and after a final centrifugation of three minutes in a calibrated centrifuge tube at 500 r.p.m. the packed cells were suspended in a hundred times their volume in a mixture consisting of 6 per cent ox serum and a synthetic solution (Waymouth, C., personal communication) which contained phenol red in a concentration of 0·0015 per cent. 10-ml. amounts were pipetted into 80-mm. Carrel flasks or 6-oz. flat-sided 'Pyrex' bottles, and the cultures were incubated at 36° C. Antibiotics were added to all solutions (100 units penicillin and 100 μgm. streptomycin per ml.); the supernatant fluid was changed every 48 hr. Patches of epithelial cells were observed on the second day and a continuous cell layer formed in four to eight days; ox embryo kidney and calf kidney cultures took less time to form the monolayer than the pig kidney cultures. The cell sheet consisted mainly of epithelial cells; but fibroblasts were present especially after long incubation.

The strains of virus used were as follows:

*Foot-and-mouth disease.* (1) Strain 997 of Waldmann *O* type (*O* 997). This strain, originally recovered from an outbreak of the disease in cattle in Great Britain, has been maintained for three years by passage in surviving epithelial tissue from the tongues of cattle. A filtrate of this culture virus was used to initiate the series of passages in the ox embryo kidney cultures. (2) Strain *M* 11, Vallée *O* type (*M* 11). This strain was originally recovered from an outbreak of disease in cattle in Mexico. A filtrate of tongue epithelium suspension from the twelfth cattle passage was used for calf kidney cultures. Virus of the same cattle passage was passaged four times in pigs, and a filtrate of the fourth-passage foot epithelium was used as starting material for the infection of the cells of the pig kidney cultures.

*Vesicular stomatitis.* A strain of virus of the Indiana type (*Ind. C*) maintained by passage in hen eggs for several years. Pooled egg fluid was used as a source of virus.

Serial passage in tissue culture was made by transferring the supernatant fluid of an infected culture, diluted with phosphate-buffered saline, to a fresh tissue culture. At 24-hr. intervals the cultures were examined under a low power of the microscope, and the supernatant fluid withdrawn for titration. In the case of the virus of foot-and-mouth disease, the titration was carried out by the intraperitoneal inoculation of 7-day old mice[4] with the appropriate serial dilutions and in later experiments by the plaque-count method on pig kidney cultures. The virus of vesicular stomatitis was titrated by the plaque-count method using chick embryo monolayers[1]. The overlay for the cultures consisted of 1·8 ml. of 2·8 per cent washed agar, 1·8 ml. of two-fold Earle's saline[5], 1·2 ml. of synthetic solution and 0·75 ml. of ox serum.

In Table 1 are shown the details of the titres obtained at each passage of the virus of foot-and-mouth disease, strain *O* 997, in cultures of ox embryo kidney and calf kidney together with the dilution at each passage. Evidence of multiplication of the virus is clear, since

Table 1. MULTIPLICATION OF THE VIRUS OF FOOT-AND-MOUTH DISEASE, STRAIN *O* 997, IN OX EMBRYO KIDNEY CULTURES AND IN CALF KIDNEY CULTURES

| Source of virus | Passage | Time after inoculation (hr.) | Dilution from previous passage or filtrate | Titre (mouse *ID*50/ml.) |
|---|---|---|---|---|
| Filtrate of supernatant culture fluid of surviving tongue epithelium | | 42 | | $3 \cdot 3 \times 10^4$ |
| Ox embryo kidney cultures | 1st | 48 | 1 : 100 | $3 \cdot 3 \times 10^4$ |
| Ox embryo kidney cultures | 2nd | 24 | 1 : 50 | $> 10^6$ |
| Ox embryo kidney cultures | 3rd | 24 | 1 : 50 | $10^6$ |
| Ox embryo kidney cultures | 4th | 24 | 1 : 100 | $10^7$ |
| | | 48 | | $10^6$ |
| Filtrate of above | 4th | 24 | 1 : 100 | $10^6$ |
| Calf kidney culture | 1st | 21 | 1 : 10 | $5 \cdot 3 \times 10^6$ |
| | | 44 | | $3 \cdot 3 \times 10^6$ |
| Filtrate of above | 1st | 21 | 1 : 100 | $3 \cdot 3 \times 10^4$ |
| Calf kidney culture | 2nd | 24 | 1 : 20 | $8 \times 10^6$ |
| ,, ,, ,, | 3rd | 24 | 1 : 50 | $6 \times 10^7$ |
| ,, ,, ,, | 4th | 24 | 1 : 50 | $6 \times 10^6$ |
| Total dilution | | | $1 \cdot 25 \times 10^{17}$ | |

after four passages in ox embryo kidney cultures and four in calf kidney cultures the titre at 24 hr. was 6 × 10$^{6}$ mouse *ID*50 per ml., although the original inoculum had been diluted by a factor of 1·25 × 10$^{17}$. On microscopic examination of the infected cultures, small clusters of necrotic debris could be seen lying among the cells of the monolayer; but the cells were unaffected and continued to metabolize as shown by the change in colour of the phenol red in the medium. Some cultures in which multiplication had occurred were fixed and stained with hæmotoxylin and eosin after 48–72 hr. incubation. In these cultures the cells were less numerous than in control cultures without virus, but showed no gross pathological change. Epithelial cells and a few fibroblasts could be detected in both sets of cultures.

In the course of three passages in calf kidney cultures, the original inoculum of the virus of foot-and-mouth disease, strain *M* 11 (titre 2·1 × 10$^{8}$ mouse *ID*50 per ml.), was diluted by a factor of 5 × 10$^{4}$, and the titre of the third passage at 24 hr. was 6 × 10$^{6}$ mouse *ID*50 per ml. The infected cultures showed the same change as that described for strain *C* 997, namely, clusters of necrotic tissue lying among healthy cells.

The virus of vesicular stomatitis, strain *Ind. C*, an egg-passaged strain, multiplied readily in calf kidney cultures. The titre of the second passage at 24 hr. was 2 × 10$^{7}$ plaque-forming doses/ml., whereas the initial titre was 7 × 10$^{3}$ plaque-forming doses/ml. In contrast to the action of the virus of foot-and-mouth disease in calf kidney cultures, the increase of the virus of vesicular stomatitis, strain *Ind. C*, was accompanied by destruction of all cells. 24 hr. after the addition of a small amount of virus, patches of round cells could be seen among the healthy cells in the monolayer, and by 48 hr. no cells remained on the glass surface of the culture flask, but round cells and necrotic debris were floating in the medium. The addition of a large amount of virus caused destruction of the cells by 24 hr. All types of cell in the culture appeared to be affected.

The virus of foot-and mouth disease, strain *M* 11, derived from the fourth-passage foot epithelium of the pig multiplied readily in pig kidney cultures. Titres not less than 10$^{6}$ mouse *ID*50/ml. were consistently recorded at each passage after 24 hr., and at the eighth passage the titre was 5·9 × 10$^{6}$ plaque-forming doses/ml., although the original inoculum (titre 2·1 × 10$^{8}$ mouse *ID*50/ml.) had been diluted by a factor of 1 × 10$^{25}$. From the first passage onwards the multiplication was accompanied by destructive changes in the culture. The epithelial cells lost their polygonal shape, became round and floated off the glass into the medium. Not all the epithelial cells were affected at the same time, but by 48–72 hr. only a few fibroblasts remained attached to the glass surface. Dilutions of the sixth-passage virus in phosphate-buffered saline were used to infect cultures, and after ½ hr. adsorption at 36° C. the monolayers were covered with an agar overlay. After 48 hr. incubation they were stained with a 1/20,000 solution of neutral red in Earle's saline[5]; on removal of the solution, plaques could be seen. They appeared as pale areas of irregular shape 1–4 mm. in diameter, surrounded by the living cells which had been stained by the neutral red. Microscopic examination showed that the central zone of the plaque consisted of unstained necrotic debris; around it could be seen unstained round cells, similar to those already described, and strands of stained epithelial cells and fibroblasts which, projecting towards the centre among the round cells, gave the plaque its irregular outline. Plaques have also been produced at the eighth and subsequent passages, and titrations performed so far appear to give support to the demonstration by Dulbecco and Vogt[3] of a linear relationship between number of plaques and virus concentration. In Table 2 is set out the number of plaques obtained at each dilution of the eighth-passage virus. Although many comparative titrations have not been made, the titres obtained by mouse inoculation and by plaque count are in fair agreement. For example, the titre of the eighth passage by plaque count was 5·9 × 10$^{6}$ plaque-forming doses/ml. and by mouse inoculation it was 10$^{7}$ mouse *ID*50/ml. Both the destructive effects of the virus on the cells of the monolayer and the formation of plaques can be inhibited by the addition of immune serum to the virus, indicating that both effects are produced by the action of the virus. Virus from the fourth and sixth passage inoculated into pigs caused the appearance of typical lesions of foot-and-mouth disease.

Table 2. MULTIPLICATION OF THE VIRUS OF FOOT-AND-MOUTH DISEASE, STRAIN *M* 11, IN PIG KIDNEY CULTURES: NUMBER OF PLAQUES AT EACH DILUTION OF VIRUS

| Source of virus | Dilution of virus (0·1 ml.) | No. of plaques per culture | Average | Titre (plaque-forming dose/ml.) |
|---|---|---|---|---|
| *M* 11 Pig kidney culture 8th passage 24 hr. | 1 : 10$^{2}$<br>1 : 10$^{3}$<br>1 : 10$^{4}$<br>1 : 10$^{5}$ | Confluent<br>Confluent<br>74, 42<br>7, 5 | —<br>—<br>58<br>6 | —<br>—<br>5·8 × 10$^{6}$<br>6 × 10$^{6}$ |

The virus of foot-and-mouth disease, strain *C* 977, from the fourth passage in calf kidney culture was used as inoculum for pig kidney cultures; the titre of the fourth-passage organism at 20 hr. was 10$^{6}$ mouse *ID*50/ml., although the original inoculum (titre 5·3 × 10$^{5}$ mouse *ID*50/ml.) had been diluted by a factor of 4 × 10$^{11}$. During its multiplication, strain *C* 997 produced destructive changes on the cells of the culture similar to those described for strain *M* 11. An attempt at the third passage to produce plaques was successful, and they showed no apparent difference from those caused by strain *M* 11.

The behaviour of the virus of vesicular stomatitis, strain *Ind. C*, on pig kidney cultures resembled closely its behaviour on the calf kidney cultures. A titre of 8·4 × 10$^{7}$ plaque-forming doses/ml. was obtained at the second passage after 42 hr., although the original inoculum derived from the second passage in the calf kidney culture (titre 5·7 × 10$^{7}$ plaque-forming doses/ml.) had been diluted by a factor of 5 × 10$^{7}$. Multiplication of the virus was accompanied by cell destruction from the first passage onwards.

The specificity of the viruses used was checked by complement fixation tests on infected cultures or on virus suspensions from susceptible animals used in titration.

The fact that multiplication of the viruses of foot-and-mouth disease and vesicular stomatitis has been shown to occur in monolayer tissue cultures of the calf and pig kidney suggests the possibility that the viruses might multiply in the kidneys of infected animals. However, no gross pathological changes which could have been taken as evidence of multiplication have been described, and although the virus of foot-and-mouth disease has been demonstrated in the kidneys of animals slaughtered at the height of infection, the amount of virus present was never greater than could be accounted for by the blood present in the organ[6].

The difference in cytopathogenicity *in vitro* of the two viruses is interesting in view of the similarity of the site and type of lesions in the infected animal. The virus of vesicular stomatitis grew well in all the cultures, destroyed all types of cells present, and produced round plaques on ox embryo kidney monolayers (unpublished observations, 1954). The virus of foot-and-mouth disease grown in the calf kidney cultures caused little damage to the cells, and consequently the calf kidney monolayers were not suitable for plaque production. In the pig kidney cultures the virus destroyed the epithelial cells and plaques could be produced. The presence of a few fibroblasts resistant to destruction by the virus gave the plaques the irregular outline referred to above; but this should not seriously detract from the usefulness of the plaque count method for the titration of the virus.

The strains of the virus of foot-and-mouth disease employed were both 'cattle' strains in that they were recovered originally from field outbreaks in cattle and have been maintained since by passage only by inoculation of cattle or by culture in cattle tissue. Strain *M* 11, which has been used in other experiments in this Institute, has proved to be highly invasive for cattle, producing regularly an extensive generalized infection in contact exposure tests. In pigs, on the other hand, it has been found recently in contact exposure tests that *M* 11 is of low invasiveness for pigs, inapparent infection being more frequent than overt infection. It seems surprising, therefore, that the cytopathogenic changes were greater in pig kidney cultures than in calf kidney cultures. Although only two strains of the virus of foot-and-mouth disease have been used, it appears likely that this difference is due rather to some property of the tissue culture than of the virus strain.

The differences between the pathological changes produced by the viruses of foot-and-mouth disease and vesicular stomatitis in the kidney monolayers studies are of fundamental interest for research on the virus–cell relationship. Both viruses have multiplied readily in spite of these differences, and these cultures therefore suggest a source of material other than tongue epithelial tissue for virus production; but it is perhaps the use of the pig kidney monolayer cultures for the accurate titration of the virus and the isolation of pure-line strains of virus that are of most immediate application in foot-and-mouth disease research.

It may be noted that the virus of vesicular exanthema, which produces similar lesions in pigs, has been successfully grown with cytopathogenic changes in pig kidney tissue cultures by McClain *et al.*[7] and now by me. In addition, I have demonstrated, with two strains of the virus of different immunological type, the formation of plaques with the agar overlay method. The plaques resemble in morphology those produced by the virus of foot-and-mouth disease. Titrations of the virus of vesicular exanthema have been carried out by the plaque count method, and I have shown also that the effects of the virus on the cells of the monolayer and the formation of plaques were inhibited by the addition of the appropriate type-specific immune serum, to the virus.

# BLOOD COUNTS IN DOMESTIC ANIMALS IN THE GOLD COAST

By Prof. E. E. EDWARDS

Department of Zoology, University College of the Gold Coast, Achimota, Gold Coast

AND

J. M. JUDD and F. A. SQUIRE

Department of Tsetse Control, Achimota, Gold Coast

In the course of investigations carried out at our laboratories at Achimota on the trypanosomes of domestic animals in the Gold Coast, it has been found that the hæmatological values obtained for goats and sheep healthy in appearance and apparently free from trypanosomes differ appreciably from those given by Drastich[1] and Wintrobe[2]. It must be emphasized that their figures are based on a total of six goats and five sheep compared with our own observations on nineteen goats and nine sheep, with a total of 187 counts in the former and 41 in the latter. In our hæmatological studies, there were two distinct types of both goats and sheep: (*a*) West African dwarf goat, (*b*) West African long-legged goat (sahel), (*c*) West African dwarf forest sheep, and (*d*) West African long-legged sheep. These breeds of goats and sheep constitute the main types encountered in the Gold Coast and indeed over the greater part of West Africa. The West African dwarf goat and the West African dwarf forest sheep originally occurred in the whole area of West Africa south of lat. 14° N., whereas the West African long-legged goat and the West African long-legged sheep had their origin farther northwards into the interior of Africa.

The hæmatological values given in Tables 1–4, and corpuscular constants shown in Table 5 (for fifteen West African dwarf goats and four West African long-legged goats and based on 167 and 20 blood counts, respectively), are in general agreement with those of Drastich and Wintrobe. The methods of determination used in the present work were: red blood cell and leucocyte counts, Dacie[4]; packed cell volume and erythrocyte sedimentation rate, Wintrobe[2]; hæmoglobin, M.R.C. grey wedge photometer[3]; anticoagulant used, double oxalate mixture[4]. It would

Table 1. BLOOD COUNTS IN 15 WEST AFRICAN DWARF GOATS

| Index of animal | No. of counts | Red blood cells (mill./c.mm.) | Vol. of packed red cells (ml./100 ml.) | Hæmoglobin (gm./100 ml. blood) | Leucocyte count (thousands/c.mm.) |

| Long-legged sheep | " " | 8·54 | 25·9 | 9·3 | 8·59 | 30·29 | 10·88 | 35·91 |

seem, therefore, that the low values for the number of erythrocytes recorded, in the third column of Table 5, for these goats in the Gold Coast are accurate standards for these animals in this region of West Africa.

The marked differences evident in column 7, Table 5, between the mean corpuscular volume of the erythrocytes of the sheep investigated by us and that cited for sheep by both Drastisch and Wintrobe are due to the much higher values recorded by them for the volume of packed red cells (column 4, Table 5). These figures, taken by themselves, indicate that the red blood corpuscles of the West African dwarf forest sheep and the West African long-legged sheep in the Gold Coast are smaller than those regarded as normal for sheep, at least, when based on determinations quoted by Drastisch and Wintrobe.

In addition to the hæmatological values included in Tables 1–5, the erythrocyte sedimentation-rate was also recorded in all cases, and it varied, irrespective of the breed of the animal, in the goat from 0 to 1·0 and in the sheep from 0 to 5·0 mm. in one hour. In many of the goats, the fragility of the erythrocytes was also measured in different strengths of sodium chloride solutions[6]. All of them showed a very high degree of fragility of their red cells, the hæmolysis being slight at 0·8 and virtually complete in all cases at 0·65 per cent concentration.

Judging from these results, and also from general observations made on the blood content of other domestic animals, particularly cattle and horses, in the Gold Coast, it would seem that apparently healthy animals in this territory either have an inherently lower hæmatological value than the normal standards, or that they suffer from the effects of some anæmia-producing factor or factors so far undiscovered. The anæmia might well be due to some dietary deficiency for normal blood production, or to a pathenogenic organism hitherto undemonstrated. It is noteworthy in this respect that similar findings have been recorded in Africans of the Gold Coast by Colbourne, Edington and Hughes[7]. Further, trypanosomes of various species, especially *Trypanosoma vivax* and *T. congolense*, frequently cause in farm animals in the Gold Coast, besides an acute type of trypanosomiasis, an insidious and chronic form of disease; this, although producing an anæmic condition, often proves exceedingly difficult to recognize clinically or by examination of blood smears for the presence of the parasites, even when repeated daily over many weeks.

No blood parasites were detected, however, at any time in the goats and sheep included in these studies, and the internal worms were entirely confined to nematodes, judging by the ova recovered in samples of the fæces. Even the nematode infections were light, the number of ova seldom exceeding 1,500 per gm. of fæces. As expected, *Haemonchus contortus* constituted by far the most abundant species.

## Identity of Cephalosporin *N* and Synnematin *B*

A SPECIES of *Cephalosporium* isolated in Sardinia was reported, in 1948, to produce an antibiotic which inhibited the growth of a number of Gram-positive and Gram-negative bacteria[1]. This antibiotic, which was only obtained in a crude form, was not characterized chemically. In 1949 certain members of the genus *Cephalosporium*, including one that was believed to constitute a new species, were reported in the United States to produce a water-soluble antibiotic called synnematin[2]. In 1951 further studies were reported on the new species and its antibiotic, synnematin[3]. These studies included the determination of chemical and biological properties of the antibiotic. The new species was later named *Cephalosporium salmosynnematum*[4]. In 1951 work in England revealed that the *Cephalosporium* from Sardinia produced a family of antibiotics, cephalosporin *P* 1–5 inclusive, which could be extracted into common organic solvents, and a water-soluble antibiotic with quite different properties. The latter was named cephalosporin *N*[5]. Further work disclosed the presence of another antibiotic named cephalosporin *C* which is closely related to cephalosporin *N*[6].

In 1953 cephalosporin *N* was reported to be a new type of penicillin, and it was suggested that cephalosporin *N* and synnematin might be identical[7]. In the meantime, synnematin was separated into two components called synnematin *A* and synnematin *B*, the former being apparently less soluble in methanol than the latter[8]. Subsequent work on cephalosporin *N* showed that this substance was a penicillin the side-chain of which was derived from D-α-aminoadipic acid[9]. Cephalosporin *C* also contained sulphur and yielded D-α-aminoadipic acid on hydrolysis[6].

The toxicity of both cephalosporin *N*[10] and synnematin *B*[11] to laboratory animals is extremely low. Doses as large as 5 gm./kgm. have been given intravenously without noticeable ill-effects. Cephalosporin *N* has been reported to resemble benzylpenicillin in some of its pharmacological properties[10], and synnematin *B* has been used successfully for the treatment of *Salmonella* infections in mice, chicks and man[11].

We now wish to report that we have exchanged samples of highly purified cephalosporin *N* and synnematin *B* and have obtained strong evidence that the two substances are, in fact, identical. Assays in different laboratories have indicated that the cephalosporin *N* unit[12] is between six and nine times as large as the synnematin *B* unit[8]. The evidence for the identity of the substances may be summarized as follows:

(1) The two products showed the same relative activities (within the experimental error) against strains of *Staphylococcus aureus*, *Salmonella typhi*, *Salmonella typhimurium* and *Sarcina lutea*. The activity of both products was destroyed by incubation with penicillinase.

(2) The two products were indistinguishable, with respect to antibacterial activity, when run on paper chromatograms in a variety of solvent systems. In each case the activity was associated with the major ninhydrin-positive spot. Similarly, the products were indistinguishable when subjected to ionophoresis on paper at *p*H 7.

(3) After hydrolysis with acid, the sample of synnematin *B*, like that of cephalosporin *N*, showed two main spots on paper chromatograms, corresponding to penicillamine and D-α-aminoadipic acid respectively. D-α-Aminoadipic acid was isolated from the hydrolysate. Dinitrophenyl α-aminoadipic acid was isolated from a hydrolysate of the product obtained by allowing synnematin *B* to react with 1-fluoro-2 : 4-dinitrobenzene.

## Some Observations on the Crystal Structure of a Chlorine-substituted Vitamin $B_{12}$

WE have recently obtained direct confirmation of the correctness of certain features of our outline structure of vitamin $B_{12}$[1] in a rather interesting way.

It has been shown by Ford *et al.*[2] that an *E. coli* mutant requiring $B_{12}$ can produce biosynthetically, from factor *B* and various substituted benziminazoles, vitamin $B_{12}$ analogues containing benziminazoles other than 5 : 6-dimethylbenziminazole. One of these, in which the two methyl groups are replaced by chlorine atoms, has since been prepared for us by Dr. K. H. Fantes and Mrs. C. H. O'Callaghan, of Glaxo Laboratories, by a method similar to the one previously used for obtaining the benziminazole analogue of vitamin $B_{12}$[3]. Air-dry crystals of this chlorine-containing compound give X-ray photographs which are exceedingly similar to those of air-dry vitamin $B_{12}$; only in a few cases, changes in the relative intensities of the weaker X-ray reflexions can be observed by eye. From measured intensities recorded on a Weissenberg photograph of one of the chlorine-containing crystals, we calculated a projection of the electron density down the crystal needle axis, [001], using signs based on the cobalt atom contributions previously found for air-dry $B_{12}$ itself. The depth of the electron-density projection here is 16 A.; accordingly few, if any, of the atoms present can appear separately resolved. But at exactly the positions expected for the methyl groups from our earlier analysis, extra electron density appears

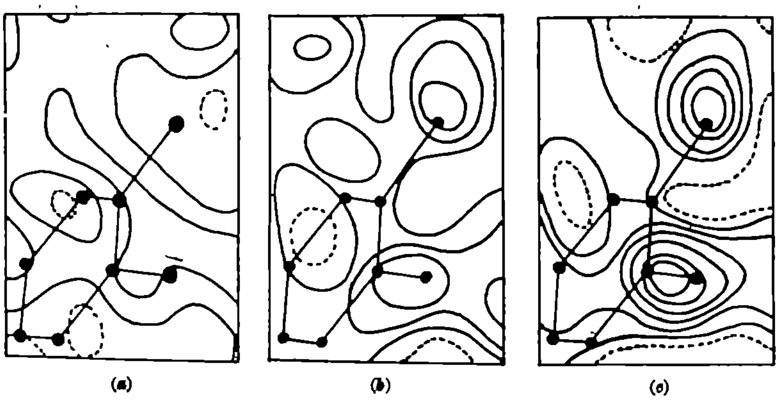

Fig. 1. Electron density over the benzene ring seen in projection down the *c* axis for (*a*) air-dried $B_{12}$; (*b*) chlorine-substituted $B_{12}$, calculated with terms having signs based on cobalt contributions alone; (*c*) chlorine-substituted $B_{12}$, calculated with terms based on signs derived through intensity changes on isomorphous replacement. Contours at intervals of 2 $e/A^2$ above the 4 *e* contour which is dotted

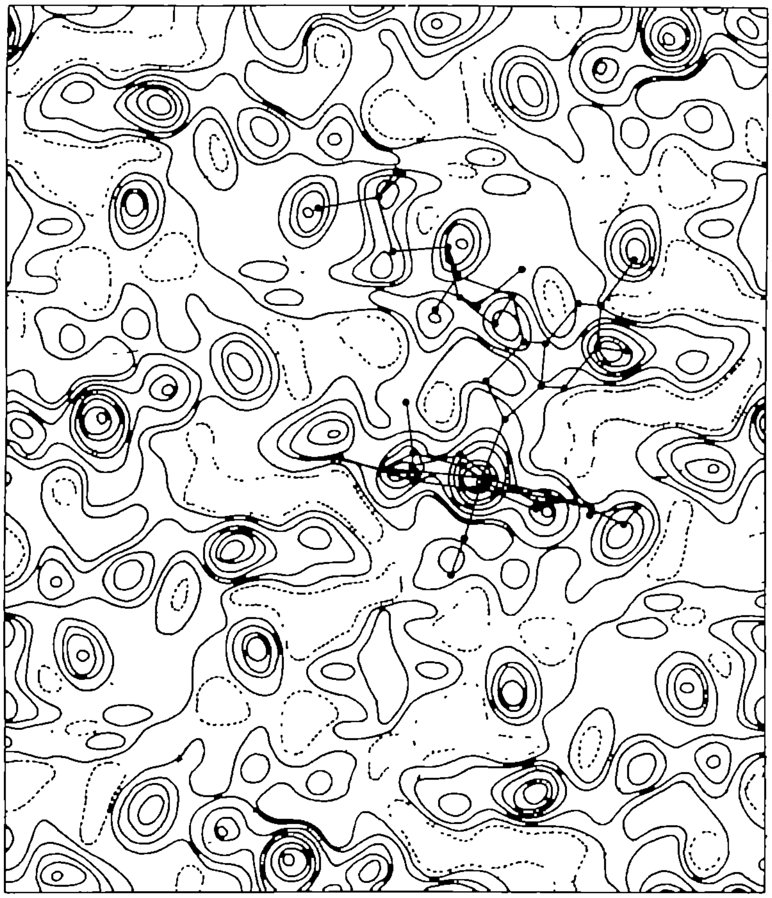

Fig. 2. Electron density calculated for chlorine-substituted vitamin $B_{12}$ seen in projection down the *c* axis and corresponding with Fig. 1(*c*). The positions derived for atoms in the 'planar' group, benziminazole, ribose and phosphate groups in air-dried $B_{12}$ crystals are drawn in

corresponding with the change methyl to chlorine (Fig. 1 *a*, *b*), while the rest of the electron-density pattern is largely unchanged. If we now accept these positions as the sites of the methyl or chlorine groups, we can calculate precisely the changes to be expected in the structure factors from the changes in scattering factor methyl to chlorine. Direct comparison with the observed changes shows good general agreement and makes it possible considerably to improve the sign determination over that based on the cobalt atom positions alone; 5 terms change sign and 17 additional terms can be given signs, making it possible to insert 73 out of a total of 81 terms in a new electron-density calculation. The electron density projection shown in Fig. 1 *c* and Fig. 2 is the new, sign-determined, projection of electron density for the chlorine-containing vitamin.

These observations prove that the atoms of the benziminazole group are closely in the positions derived for them in the earlier work on vitamin $B_{12}$ itself, with N3 directly linked to the cobalt atom. They also illustrate how sensitive the intensities of the X-ray reflexions are even to small changes in chemical composition and they confirm the reliability of the methods we are using for structure analysis. The absolute scale of the observed intensities, for example, we derived by the statistical method suggested by A. J. C. Wilson[4]. No modification of scale proved necessary to correlate the old observations on $B_{12}$ itself with those of the chlorine-containing vitamin. Again, neither chlorine (atomic number 17) nor cobalt (27) has a high scattering factor relative to the total $F_{000}$ of about 800 calculated for the whole $B_{12}$ molecule + water of crystallization. But both these scattering factors, and that of 16 for the difference 2Cl–2Me, are of sufficient magnitude relative to the estimated statistical average $\bar{F}_{hkl}$ of about 42, in the scale of one $B_{12}$ molecule, to be used in phase determination. The present measurements illustrate very clearly the reality of the low electron density peak pattern observed in the three-dimensional distribution calculated for air-dry $B_{12}$ with terms phased on cobalt contributions alone and previously used for atom placing; and the proof that this peak pattern was an accurate indication of the positions of the atoms of the benziminazole group gives us all the more confidence in accepting it as evidence for the structure of the chemically unknown part of the $B_{12}$ molecule[4].

The use of micro-organisms for synthesizing heavy-atom derivatives for crystallographic purposes is not quite new. Dr. E. Kleiderer and Dr. O. Behrens (Lilly Laboratories) did very kindly prepare iodobenzylpenicillin by a similar fermentation process for crystallographic examination in 1946; only the fact that the structure of penicillin was by that time established made unnecessary the further investigation of this compound by X-ray analysis. It seems likely that this synthetic approach may prove useful in other still more complex investigations of natural products.

We are much indebted to Dr. K. Fantes, Mrs. O'Callaghan and Dr. E. Lester Smith for the crystals of the chlorine-substituted vitamin.

## An Effect of Antibiotics produced by Plankton Algae

The clear blue oceanic water in the tropics and subtropics, where the standing crops both of phytoplankton and zooplankton are extremely low—the reason why the water is so clear and blue—should on this account show very low organic productivity by the plankton algae. Measurements with the carbon-14 method have shown this to be true[1].

So-called 'light-and-dark bottle' oxygen experiments by Riley[2], verified by other workers, seem, however, to indicate that the areas with the clear, blue water should be some of the most productive sea areas of the world. Steemann Nielsen[1] therefore rejected the use of the oxygen method in clear oceanic water. The difference in oxygen consumption between light and dark bottles, which was assumed by Riley to be due to photosynthesis, may have nothing to do with this process. It was suggested that antibiotics produced by the plankton algae in the light reduce the intense bacterial activities occurring in the dark bottles as soon as natural sea water is enclosed in bottles. In ocean water from all depths, about 5 mgm. organic matter is present per litre. The intense bacterial activity does not occur if the water is *in situ* (Keys, Christensen and Krogh[3]). The presence of the surface at the inner walls of the bottles is responsible for the bacterial growth[4].

Laboratory experiments with the freshwater green alga *Chlorella pyrenoidosa* and the marine diatom *Thalassiosira nana* have now produced the experimental background for this suggestion. Two of these experiments are presented below.

(1) Normal culture medium for *Chlorella* containing 8 mgm. glucose and 4 mgm. peptone per litre was incubated with bacteria, and a definite very small number of *Chlorella*. The rate of photosynthesis per cell was measured in advance in a special experiment using a higher concentration of the alga but the same oxygen technique as in the main experiments. Normal 'light-and-dark bottle' oxygen experiments were carried out here lasting three days including three light periods (44 hr. altogether) alternating with three dark periods. The rate of photosynthesis during the whole experiment, computed from the special experiment and corrected for growth, was 0·024 ml. oxygen per litre.

| | |
|---|---|
| Oxygen consumption in dark bottles | 3·59 ± 0·02 ml. oxygen per litre |
| Oxygen consumption in light bottles | 2·92 ± 0·03 ml. oxygen per litre |
| Reduction in oxygen consumption in light bottles compared with dark bottles | 0·67 ± 0·04 ml. oxygen per litre |

The oxygen consumption in the dark bottles is due to the respiration by the bacteria. The rate of this respiration is thus reduced in the light bottles. It is evident that the difference between the light and the dark bottles is not due to *Chlorella* photosynthesis, which constitutes only 3–4 per cent of this difference. In a corresponding series made simultaneously with bacteria but without *Chlorella* added, the oxygen consumption was the same in the light and in the dark bottles.

(2) Similar experiments were carried out with a culture of the marine plankton diatom *Thalassiosira nana* inoculated with bacteria from the Sound. In a 'light-and-dark bottle' oxygen experiment lasting three days (48 hr. in the light), oxygen consumption was 4·96 ml. per litre in dark bottles and 4·34 ml. in light bottles. The reduction in light bottles compared with dark bottles was 0·62 ml. oxygen per litre. According to experiments made with a 300-times higher concentration of the diatom during 4 hr., the rate of photosynthesis per 48 hr. in the main experiment—corrected for growth—was 0·035 ml. oxygen per litre. Photosynthesis presents thus only 5·7 per cent of the difference between the light and dark bottles.

The experiments presented show that the presence of algae, presumably due to production of antibiotic, effects a reduction in the oxygen consumption of the bacteria in the light bottles. The production of antibiotics by plankton algae has been shown, for example, by Pratt *et al.*[5]. It was verified during the present investigation that antibiotics may be found in filtrates from algal cultures.

Whereas in oligotrophic water in Nature the reduction of bacterial respiration due to antibiotics makes the oxygen technique inapplicable for measuring organic productivity, the influence in eutrophic water must be very limited.

## A Possible New Vitamin $A_1$ Isomer in the Eyes of Crustaceans

In a recent communication, Kampa[1] reports a new photosensitive pigment in the eyes of euphausiid crustaceans. This prompts the recording of some observations at this laboratory from a series of investigations of vitamin A components in marine animals.

During this investigation we recently obtained a fresh sample of the deep-sea prawn, *Pandalus borealis*. The vitamin A content of the eyes of this decapod was determined by our routine method, namely, chromatography of the unsaponifiable matter mainly according to Gridgeman *et al.*[2]. The ultra-violet absorption curve departed to the left from the expected vitamin $A_1$ curve, $E_{310 m\mu}/E_{325 m\mu} = 0{\cdot}926$, $E_{300 m\mu}/E_{325 m\mu} = 0{\cdot}823$, and $E_{350 m\mu}/E_{310 m\mu} = 0{\cdot}424$. The vitamin A content was 150 I.U. per gm. fresh tissue. No vitamin $A_2$ was present, $E_{693 m\mu}/E_{620 m\mu}$ in the Carr–Price reaction being 0·005.

The maleic acid anhydride reaction, according to Robeson and Baxter[3], gave 70·6 per cent recovery, showing mainly or only *cis*-configuration. The prawns had been exposed to daylight during sampling and removing of the eyes, thus complete bleaching may be assumed. These results, together with the biological potency of 50 per cent compared to the chemical estimations as observed by Fisher *et al.*[4], point to the occurrence of a new vitamin $A_1$ isomer in crustacean eyes, possibly the Δ-3.5-di-*cis*-isomer, postulated by Hubbard and Wald[5]. Unfortunately, fresh samples of these crustaceans cannot be obtained until next winter, thus further investigations have to be postponed.

# High-potency Vitamin $A_2$ Oils from Indian Freshwater Fish

Vitamin $A_1$ occurs predominantly in the liver oils of marine fish, whereas vitamin $A_2$ is found largely in freshwater fish liver oils. The mode of action of vitamins $A_1$ and $A_2$ is not certain; but their role in vision, giving rise to the pigments rhodopsin and porphyropsin respectively, in the retina is now well established[1]. Due to paucity of high-potency freshwater fish liver oils as well as their labile nature, vitamin $A_2$ has not yet been obtained in a crystalline form. The spectroscopic properties[2,3] and the biological activity[4] of vitamin $A_2$, which is approximately 40 per cent of that of vitamin $A_1$, have been determined with the purest preparation obtained.

Data on the vitamins A content of Indian freshwater fish liver oils measured spectrophotometrically are not available, and not much is known of the relative distribution of vitamins $A_1$ and $A_2$. The present communication gives the result of work carried out on fish in large freshwater reservoirs in the States of Mysore and Madras.

Fresh livers were ground with acid-washed sand and anhydrous sodium sulphate, and oil was extracted with light petroleum (40–60°). The combined extracts were reduced in bulk at low pressure (yield of oil, approximately 5 per cent). An aliquot of the oil was saponified, made up to a known volume in spectroscopic *cyclo*hexane, and absorption spectra and colour test were determined without delay using a Beckman spectrophotometer. The assay of the oil was carried out according to the standard spectrophotometric method of Cama and Morton[3]. The vitamins $A_1$ and $A_2$ content of these highly potent oils are recorded in Table 1. Investigations by chromatographic technique[5] on the oils were also carried out using 5 per cent weakened Merck alumina. The results on one oil are recorded in Table 2.

Table 1. Spectroscopic Data on Freshwater Fish Liver Oils using Ultra-violet Spectra and the Antimony Trichloride Colour Test

Gross *E*(1%, 1 cm.) at 350 mμ of the whole oil, 127·0. Total *E*(1%, 1 cm.) at 350 mμ of the fractions, 121·128.

* Expressed in terms of weight of original oil.

From the results in Table 1, it is evident that vitamin $A_2$ predominates largely over vitamin $A_1$ ($A_2/A_1$ approximately 9/1). Moreover, the oils have a very high vitamin $A_2$ content relative to oils previously reported in the literature[6]. Chromatographic investigations show that most of the vitamin $A_2$ in the oil is present in the ester form without the simultaneous presence of vitamin $A_1$ ester (presence of 693 mμ band and absence of 620 mμ band with the antimony trichloride colour test on the vitamin $A_2$ ester fraction). Vitamin $A_1$ is present in the alcohol form only, and a small amount of vitamin $A_2$ alcohol was also present. This was also confirmed for the other two highly potent oils.

Attempts are being made to extract large quantities of such typical oils for further detailed studies and characterization.

We wish to thank Dr. H. D. R. Iyengar, fisheries officer, Mysore State, and Mr. M. Unni, assistant director of fisheries, Mettur Dam, for help in procuring the fish livers in a fresh condition, and Prof. K. V. Giri for his interest in the work. The financial assistance of the Council of Scientific and Industrial Research is gratefully acknowledged.

## Adrenaline and Noradrenaline in Tissues of Normal, Insulin-treated, and Adrenalectomized Rats

ADRENALINE and noradrenaline have been estimated in nine rat tissues using an extension of the method of Weil-Malherbe and Bone for blood[1–3]. Satisfactory evidence for the specificity of the procedure has been obtained from comparisons with biological assay and by paper chromatography. The mean concentrations of noradrenaline and adrenaline in rats with a mean weight of 235 gm., and the means of the percentages of adrenaline in the mixture of amines (referred to below as 'adrenaline/catechol ratio') are shown in Table 1. The latter is both higher and more uniform than has been found by other workers and corresponds with the higher 'adrenaline/catechol ratio' found by Weil-Malherbe and Bone in blood[2,3]. The distribution of noradrenaline does not appear to support the current hypothesis that in general its concentration can be correlated with the density of adrenergic nerve fibres[4,5].

Table 1

| Organ | Noradrenaline (mμgm./gm.) | Adrenaline (mμgm./gm.) | Adrenaline (per cent) |
|---|---|---|---|
| Heart (20)* | 530 ± 47·7 | 179 ± 19·0 | 25·9 ± 1·66 |
| Brain (6) | 458 ± 53·8 | 212 ± 8·05 | 30·7 ± 1·71 |
| Spleen (8) | 230 ± 45·9 | 74·4 ± 12·9 | 25·4 ± 2·62 |
| Diaphragm (20) | 219 ± 12·0 | 54·1 ± 6·53 | 19·6 ± 2·12 |
| Kidney (20) | 158 ± 17·3 | 42·7 ± 5·00 | 21·9 ± 1·48 |
| Liver (20) | 87·1 ± 7·23 | 24·6 ± 3·64 | 21·0 ± 1·68 |
| Retroperitoneal fat (8) | 62·0 ± 13·8 | 20·2 ± 5·57 | 23·1 ± 3·79 |
| Lung (8) | 61·6 ± 7·33 | 22·9 ± 1·57 | 28·0 ± 2·78 |
| Leg muscles (20) | 52·4 ± 3·90 | 15·0 ± 1·53 | 22·4 ± 1·80 |

* Number of estimations

The effects of insulin on the concentrations of adrenaline and noradrenaline in heart, kidney, liver, diaphragm and leg muscles have been investigated by analyses carried out 2½ hr. after subcutaneous injection of 7 units insulin/100 gm. body-weight. Insulin produced significant increases ($P < 0.01$ or $0.001$) of the 'adrenaline/catechol ratio' in all five organs. There were significant increases ($P < 0.001$) in the absolute concentrations of adrenaline in heart and kidney (64 and 42 per cent respectively), and a significant increase (23 per cent) of noradrenaline in the heart. The increased concentrations of adrenaline brought about by insulin were not nearly so marked as those found by Hökfelt[6] in the heart and liver of rats; this may be largely due to his lower initial concentrations of adrenaline. In contrast also to his findings, there were only probably significant differences between the effects of insulin actions of ½, 2 and 3½ hr. duration.

The concentrations of adrenaline and noradrenaline in heart and kidney were investigated six weeks after bilateral demedullation, and three to four weeks after bilateral adrenalectomy in untreated rats and in rats given insulin. Both operations reduced the adrenaline concentrations of heart and kidney, and in kidney the noradrenaline concentration was also reduced; in the heart it was increased. The greatest change was a 31 per cent loss of noradrenaline in the kidney.

In demedullated and adrenalectomized rats, insulin did not significantly increase the adrenaline concentration of either heart or kidney ($P > 0.1$), but still produced probably significant increases of the 'adrenaline/catechol ratios'. The altered effect of insulin on adrenaline concentration brought about by operation was very significant for heart muscle ($P < 0.001$). In heart muscle, operation also significantly altered the effect of insulin on noradrenaline concentration, from an increase to a decrease. The changes of adrenaline and noradrenaline concentrations which are produced by insulin in hearts of normal rats seem therefore to depend on medullary secretion. This may be in contrast to kidney, in which operation changed, probably significantly, only one of the effects of insulin, namely, it reduced the usually large rise in adrenaline concentration.

The presence of fairly high concentrations of adrenaline and noradrenaline in heart and kidney some weeks after adrenalectomy seems to indicate the ability of the rat to synthesize or store these amines, either in the heart and kidney, or in other organs from which transfer takes place. Transfer to the kidney occurs in the course of excretion[3].

Three experiments have been carried out on the effect of age (weight) on the percentage of adrenaline in the mixture of catechol amines in the heart and kidney of normal rats and of rats given insulin. The 'adrenaline/catechol ratios' are shown in Table 2.

Table 2

| | Mean weight of rat, 145 gm. | Mean weight of rat, 240 gm | Difference |
|---|---|---|---|
| Heart (untreated) | 21·2 per cent | 26·5 per cent | + 5·3 |
| Heart (insulin) | 33·6 ,, ,, | 39·1 ,, ,, | + 5·5 |
| Kidney (untreated) | 23·7 ,, ,, | 33·1 ,, ,, | + 9·4 |
| Kidney (insulin) | 35·2 ,, ,, | 39·5 ,, ,, | + 4·3 |

The 'adrenaline/catechol ratios' were higher in both the heart and kidneys of the older rats. This ratio in the kidney was less affected by insulin in the older rats than in the younger ones.

Experiments with cortisone are being carried out, and the results, together with the above findings, will be published in detail elsewhere. The work has been supported by a grant from the Medical Research Council.

## Studies on Transaminase and Decarboxylase catalysed by Extracts of the Silkworm, *Bombyx mori* L.

IN the course of work[1] on the transamination reactions between aspartate and α-ketoglutarate mediated by extracts of the gland and intestines of the silkworm, *Bombyx mori* L., an entirely new ninhydrin-positive spot with an $R_F$ value different from either the glutamate produced or added aspartate was observed when the reaction mixture was resolved on Whatman No. 1 filter paper employing butanol/formic acid/water (10 : 2 : 5) as the solvent.

It was suggested that this additional spot represents a peptide produced by enzymic transpeptidation[2]; but further work on transpeptidation with glycyl peptides and glutathione as the substrates did not confirm this view. A more detailed examination has therefore been made of the circumstances giving rise to this additional spot.

A number of solvents were employed to achieve better separation of the various constituents encountered in this work. While solvent systems like 80·0 per cent aqueous pyridine or propanol could be successfully employed for resolving the new spot from the mixture of aspartate and glutamate, these two salts themselves were inseparable, and therefore water-saturated phenol was employed. After resolving the various constituents from the 'reaction mixture', the position due to the new spot, determined separately by running a test strip and staining it with ninhydrin, was eluted, hydrolysed and re-chromatographed; but the position of the spot on the second chromatogram did not alter and corresponded to α-alanine. On subjecting another aliquot of this sample and an authentic specimen of α-alanine to chemical deamination with nitrous acid[3], lactic acid was detected from the deamination reaction product, confirming the identity of this substance with α-alanine. The route of formation of α-alanine from aspartate is through β-decarboxylation, and therefore the enzyme which catalyses this reaction is termed β-decarboxylase.

Amino-acids active in these transamination reactions other than aspartate are α-alanine, phenylalanine and the amide of aspartic acid. Aspartate is by far the most active among these compounds. When asparagine is employed as the substrate instead of aspartate, transaminase activity is diminished by about 65·0 per cent. Decarboxylase is, however, completely inhibited, because the β-carboxyl group in asparagine is replaced by the amide linkage.

Further, there is no appreciable decarboxylation even with aspartate when the latter is employed alone as the substrate. Addition of traces of α-ketoglutarate (*M*/2,000) to enzyme–aspartate mixture in a buffer of *p*H 7·0 increases the activity to 400 per cent. This concentration of the keto-acid is so small that activity due to transamination is not appreciable and even not detectable. Dialysis of the crude extract against distilled water at 0° C. inactivates irreversibly the activity due to decarboxylase, but does not affect transaminase activity. The effect of carbonyl-trapping agents such as hydrazine, hydroxylamine and semicarbazide on both transaminase and decarboxylase are similar, and are inhibited to more or less the same extents. Addition of pyridoxal phosphate to dialysed enzyme extracts does not, however, restore the decarboxylase activity.

A similar enzyme system bringing about decarboxylation of aspartate in the β-position has been shown to occur in cell-free extracts and cell suspensions of *Cl. welchii SR* 12, which is also stimulated by the addition of traces of a large number of α-keto-acids[4].

The discovery of an enzyme system in the glands of the silkworm capable of converting aspartate to α-alanine is of particular significance from the point of view of the synthesis of precursors of silk fibroin. This mechanism secures for the organism an additional source of endogenous α-alanine, which constitutes about 20·0 per cent on the weight of silk.

I thank Profs. M. Sreenivasaya, J. V. Bhat and M. S. Thacker for their interest in this work, and the Central Silk Board for financial assistance. It is hoped to publish a fuller account elsewhere.

## Effect of 8-Azaguanine on Enzyme Formation

The dependence of enzyme formation on nucleic acids has now been established by studies with disrupted *Staphylococci*[1]. It is not yet clear whether the presence of ribonucleic acid as such or the process of synthesis of ribonucleic acid is essential for enzyme synthesis. Gale and Folkes[1] found that the development of certain enzyme systems was enhanced by the presence of ribonucleic acid extracted from the cells, whereas such extracts were without effect in promoting the synthesis of β-galactosidase, which required the presence of a mixture of purines and pyrimidines and was abolished by ribonuclease. Pardee[2], studying the formation of β-galactosidase in mutants of *Escherichia coli* requiring uracil, found that enzyme formation only took place in the presence of added uracil and, if the supply of uracil was limiting, enzyme synthesis ceased as soon as the supply of uracil was exhausted. He concluded that ribonucleic acid synthesis was essential for enzyme formation, the finished nucleic acid being metabolically inert. Similar conclusions have been drawn by Spiegelman, Halvorson and Ben-Ishai[3] as a result of investigations on inducible enzyme synthesis in *Escherichia coli* and in yeasts.

It has been shown previously that the formation of the adaptive enzyme β-galactosidase in *Staphylococcus aureus* is inhibited by the purine analogues 2 : 6-diaminopurine and 8-azaguanine, the latter becoming incorporated into ribonucleic acid[4]. It was suggested that such incorporation rendered the ribonucleic acid non-functional in enzyme formation. It has now been found that the synthesis of catalase and glucozymase by *Staphylococcus aureus* is also sensitive to azaguanine under certain conditions. When enzyme formation takes place in intact washed cells which have been grown anaerobically in glucose, and then incubated in a medium containing salts, amino-acids, glucose and galactose, the formation of β-galactosidase and catalase is almost completely suppressed by 100 μgm. azaguanine/ml. If glucose is omitted from the incubation mixture, incorporation of azaguanine is decreased and inhibition of enzyme formation lessened. Fig. 1 shows the effect of adding azaguanine to the incubation mixtures at intervals during the synthesis of β-galactosidase.

If the analogue is added at the beginning of the experiment, no enzyme formation occurs; if it is added after induction has taken place, enzyme formation is inhibited and ceases soon after the addition. Similar results have been obtained for the formation of either catalase or glucozymase, under appropriate conditions.

The inhibition of enzyme formation by azaguanine can be reversed by the further addition of guanine, xanthine or hypoxanthine. Reversal is not obtained

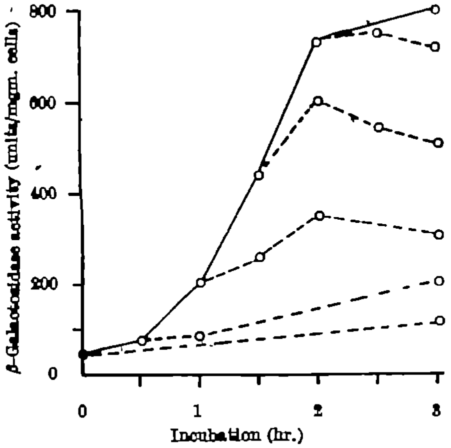

Fig. 1. Effect of time of addition of azaguanine to systems synthesizing β-galactosidase. System comprised *Staph. aureus* (2 mgm./ml.), 17 amino-acids (400 μgm./ml. of each), glucose (1 mgm./ml.), galactose (20 mgm./ml.) in a buffered salts solution. Azaguanine (100 μgm./ml.) added at time 0, 0·5, 1·0, 1·5 and 2 hr. Formation of β-galactosidase in control system shown in full lines; formation of enzyme after the addition of azaguanine shown in broken lines

by uracil or thymine and only rarely by adenine. When the inhibition is reversed by guanine, the incorporation of azaguanine into the ribonucleic acid does not diminish but there is a considerable formation of new ribonucleic acid, as measured by the incorporation of $^{14}$C-uracil. Reversal can be brought about by addition of guanine up to 90 minutes after the addition of the analogue; if incubation with azaguanine has taken place for longer than this period, no reversal of the inhibition of catalase formation can be obtained; reversal of the inhibition of β-galactosidase formation is still possible, although synthesis occurs at less than the control rate after addition of guanine.

In the case of glucozymase formation, sensitivity to azaguanine varies with the phase of culture of the cells used for the experiment. Fig. 2 shows that synthesis of glucozymase in cells harvested during the exponential phase of growth is little affected by concentrations of azaguanine which abolish β-galactosidase formation. As growth ceases, the synthesis of glucozymase becomes more sensitive to azaguanine; the synthesis of β-galactosidase is completely sensitive to the analogue at all phases of growth. It seems probable that the synthesis of β-galactosidase is dependent upon a co-synthesis of ribonucleic acid, so that the present results are in agreement with the suggestions put forward by Pardee[2] and Spiegelman *et al.*[3]. Nevertheless, the results in Fig. 2 indicate that it is not possible to draw conclusions on protein synthesis in general from studies on inducible enzymes only, since the formation of glucozymase, under certain conditions, appears to be little dependent on coincident ribonucleic acid synthesis.

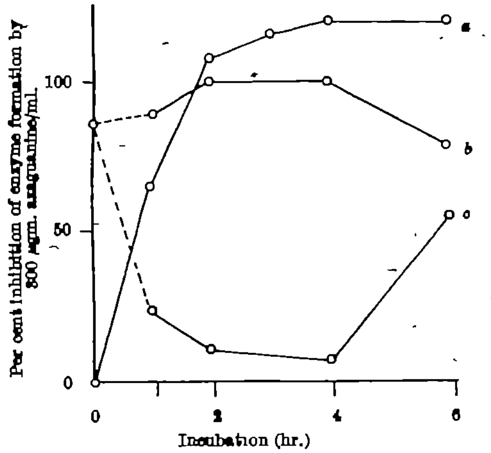

Fig. 2. Sensitivity of enzyme formation to azaguanine at various stages of growth. Cells growing in a glucose/casein hydrolysate medium. Samples were taken at times indicated and the ability of the cells to synthesize enzyme, in the system described for Fig. 1, in the presence or absence of azaguanine (300 μgm./ml.) determined. *a*, Growth; *b*, β-galactosidase formation; *c*, glucozymase formation

The above results can be correlated with the conditions necessary for the development of enzymes in disrupted *Staphylococci*, as described by Gale and Folkes[1]. They found that, whereas synthesis of glucozymase was stimulated by staphylococcal ribonucleic acid, β-galactosidase formation required a supply of purines and pyrimidines and was not affected by staphylococcal ribonucleic acid. All these findings could be explained on a basis of differing degrees of functional stability of the various nucleic acids concerned in the syntheses of different enzymes.

## Occurrence of Chitin in the Epicuticle of an Arachnid *Palamneus swammerdami*

In a previous communication[1], it has been pointed out that the epicuticle of *Palamneus swammerdami* conforms to the basic pattern suggested for insects in consisting of a non-chitinous lipoprotein layer overlaid by a layer of wax. However, more extended observations carried out since then indicate the presence of chitin in this layer, which is masked in some way so that it is not readily revealed by the usual histochemical tests. Blower[2] reported that in myriapods a layer of the cuticle, which he considered the outermost, resembles the epicuticle of insects in histochemical and staining reactions. Only the presence of chitin in it prevented him from homologizing it with the epicuticle. However, he ignored the presence of a layer external to the one he described as the outermost, for he doubted its histological validity, considering it as a diffraction effect. In a recent study of *Palamneus*[1,3], it has been shown that the layer referred to by Blower corresponds to the exocuticle and is distinct from the epicuticle, which lies external to this layer. Cloudsley-Thompson[4] also described in arachnids and myriapods a similar colourless epicuticle external to the tanned exocuticle. The present communication gives the evidence for the presence of chitin in the epicuticle.

The epicuticle of *Palamneus*, which can be separated by treatment of entire cuticle with chlorated nitric acid, is a thin whitish membrane. From a study

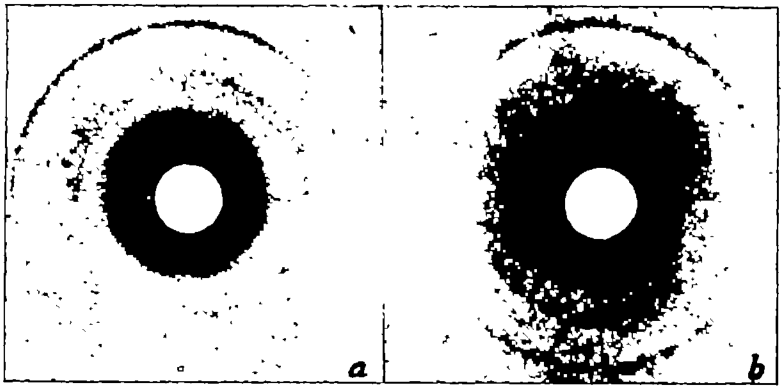

Fig. 1. X-ray diffraction patterns of (*a*) epicuticle of scorpion, and (*b*) purified chitin from cuticle of cockroach, both taken with the surface perpendicular to the X-ray beam under identical conditions (*d* = 5 cm., copper $K\alpha$ radiation)

of the sections of this membrane stained with Mallory, it was found that it agrees in all respects with the epicuticle already described[3]. X-ray diffraction patterns of this membrane taken with the X-ray beam both parallel and perpendicular to the surface showed the presence of spacings identical with those found for chitin[5]. A comparison of the diffraction pattern of the scorpion epicuticle with that of the cockroach, which is known to contain only protein, brings out clearly the entirely dissimilar nature of the two epicuticles, as the latter pattern shows no details except a central halo. On the other hand, the diffraction pattern of the scorpion epicuticle was found to show a remarkable similarity to that obtained with purified chitin (Figs. 1*a* and *b*). In view of this surprising observation, chemical tests were made on this membrane.

A portion of the membrane was prepared for the chitosan test by treating it with concentrated potassium hydroxide for 6 hr. at 180° C. On addition of iodine and sulphuric acid, it took up a deep orange colour. Controls prepared with crab cuticle showed that the epicuticle was dissolved by the potassium hydroxide treatment, and the endocuticle which survived was coloured deep violet, a characteristic of chitosan. On adding 3 per cent acetic acid the material from the crab treated with potassium hydroxide dissolved; but in the case of the scorpion epicuticle there was no such effect. However, the scorpion preparation reacted to treatment with concentrated nitric acid, by which it was disrupted. The results recorded above for the epicuticle of *Palamneus* differ in some respects from those obtained for chitin. But the fact that it is able to survive intact violent treatment such as is involved in the chitosan test is suggestive of the presence of chitin. It is remarkable that chitin is still present in the epicuticle, even though this layer has been isolated by subjecting it to prolonged treatment with chlorated nitric acid. Probably its combination with —S—S-bonded proteins may be responsible for this feature. This assumption is supported by the observation that treatment with alkaline sodium sulphide produces a disruptive effect on the material treated with potassium hydroxide. It has already been shown that alkaline sodium sulphide affects the —S—S-bonding in the epicuticle of *Palamneus*[3]. It is therefore suggested that the presence of a protein moiety in combination with chitin may be responsible for this material not giving a positive chitosan reaction.

Further confirmation of the presence of chitin was obtained by hydrolysing the epicuticular material in 4 *N* hydrochloric acid for 8½ hr. in a sealed tube at 100° C. The glucosamine content of the hydrolysate was estimated by the method of Elson and Morgan as modified by Palmer, Smyth and Meyer[6]. The estimated amount of glucosamine was found to be nearly the same as that given by purified chitin under the same conditions, as reported by Hackman[7]. A chromatographic analysis of the hydrolysate for amino-acids indicated the presence of glutamic acid. It appears that the epicuticle consists of chitin with a proportion of protein which, however, does not alter the chitin lattice structure.

A layer corresponding in all respects to the epicuticle of *Palamneus* appears to be present in *Scolopendra* also. The X-ray pattern of this layer is identical with that given by the epicuticle of *Palamneus*.

The implications of these observations in relation to the characteristic features of the epicuticle of arthropods will be discussed elsewhere.

We thank Prof. P. S. Sarma for facilities provided for chromatographic work.

## Measurement of Surface Pigmentation in Animals

An accurate method of measuring the pigmentation of human and other mammalian hair has been described[1]. This consists in dissolving the hair in urea, and, after dilution to a constant volume, measuring the extinction coefficient of the solution. The same procedure, without any modification, has been found to give reproducible results with feathers (domestic fowl), amphibian skin (common frog), fish skin (plaice) and insect scales (cabbage white butterfly and tiger moth). It seems probable that the method can be used for the estimation of surface pigmentation in all types of animals.

The work has been carried out with the aid of a grant from the Government Grant Committee of the Royal Society.

## A Method for sampling Arthropods and Molluscs from Herbage by Suction

The insect population in herbage, for example, in rough grassland, is commonly sampled by sweeping. Other arthropods such as mites, centipedes, millipedes and also slugs and snails are obtained by trapping, hand-picking, or by removing part of the habitat for extraction in the laboratory. We have developed a new, more universal method, liable to less personal error than sweeping, which extracts a very high proportion of small invertebrates from rough matted grassland with a suction pump. There is no need to remove a part of the habitat, and the method could be applied widely.

The apparatus is a portable electric blower (Type *N.W.B.E.*) as supplied by Wolf Electric Tools, Ltd., London, and run on the mains supply. A metal barrel (10 in. long, 5·5 in. diam.) is attached to the intake, and on the lid of this barrel is a flexible hose ending in a hard rubber nozzle with a 1-in. aperture. A nylon collecting bag fits inside the barrel and is kept in place by the lid. The apparatus weighs 15·5 lb., and is easily carried.

For sampling, a metal cylinder 12 in. × 12 in. is pressed into the grass, the apparatus is switched on and the nozzle worked back and forth over the area within the cylinder. Two successive extractions each of two minutes with a two-minute interval between were found to be satisfactory. Table 1 shows the extraction-rates based on this procedure and on the numbers remaining behind in the herbage and in the upper few millimetres of soil within the metal cylinder (these being sorted by hand from the material brought back to the laboratory). From approximately 23 sq. ft., 2,945 insects, 1,606 other arthropods and 189 molluscs were extracted.

Table 1

| Group | Mean extraction (per cent) | Group | Mean extraction (per cent) |

## A Water-soluble Filter for trapping Airborne Micro-organisms

In studies of airborne mould spores as a cause of respiratory allergy, there has been a need for a trap which would not only sample the air efficiently out of doors and give a measure of the number of spores per unit volume of air, but which would also allow the spores to be grown on culture media for identification.

Preliminary experiments early in 1952 indicated that a water-soluble 'wool' of sodium alginate could be used to trap spores. The sodium alginate is not available as a wool but has to be prepared from calcium alginate yarn. Initially yarns of four weights were tried (450/160; 150/60; 100/27; and 50/12, denier/filament (continuous), *Z* twist), but the most uniformly textured wool was produced by the 50 denier/12 filament yarn (from Messrs. Courtaulds, Ltd., Use-Development Organisation, 15 Cross Street, Manchester 2).

The calcium alginate yarn is cut into short lengths (5–10 mm.) and stirred into a relatively large volume of water to allow the yarn to untwist to its constituent filaments, then drained on a Buchner funnel. The resultant mass (calcium alginate 'wool') is soaked in hydrochloric acid (approximately *N*) until all calcium has been leeched out. (Test for removal of calcium by allowing a few drops of the acid solution to drip into a solution of ammonium oxalate—no precipitate indicates calcium removed.) The yarn is again drained off, suspended in 50 per cent alcohol and neutralized with sodium hydroxide. (Allow time for the strands in the centre of the mass to react with the alkali.) The yarn is now sodium alginate and is soluble in water. It receives several washes in 50 per cent alcohol, a final wash in absolute alcohol and is dried at room temperature. Best results are obtained by using throughout relatively large volumes of the suspending liquids, so that the alginate strands are always loosely suspended. The final product appears much like a wad of cotton wool, but it is soluble in water up to 1 part in 10 at room temperature. The higher concentrations are very viscous; but a 2 per cent solution in water has a viscosity about four times that of water, and a 1 per cent solution only about 1·5–2 times the viscosity of water. The wool may be sterilized dry at about 125° C.

The sodium alginate wool has been used for trapping airborne micro-organisms in the following way. The filter holder is a cylindrical brass tube 75 mm. long, 12 mm. diameter and 11 mm. bore. At one end the wall is bevelled on the outside to a sharp edge which during sampling is directed into the wind. Fixed transversely across the bore of the tube, 25 mm. from this sharp end, is a pair of crossed wires providing support for the alginate plug, which is rammed in at this end. (About 0·5 gm. of the wool packs into a plug approximately 10 mm. long, which is more than adequate.) The other end of the tube is connected to a pump. When the desired volume of air has been sucked through the plug, it is pushed out into sterile water which, after complete solution of the plug, is made up to the desired volume. Aliquots of this solution are plated out on culture media for incubation and counting.

For taking samples over several hours at the regular trapping site at St. David's Hospital, Cardiff, a wind-vane mounting similar to that described by Hirst[1] has been used for maintaining the sharp end of the filter tube facing the wind. The rate of suction through the filter is controlled at the mean wind velocity recorded at the site by a Casella three-cup anemometer, and thus sampling is approximately isokinetic[2].

To evaluate the efficiency of the plug in filtering off micro-organisms, several runs were made in which air after passing through the alginate plug was immediately bubbled through dilute agar solution. All this solution was plated out on media and incubated. These plates almost invariably remained sterile.

The alginate wool filter has proved to be very useful for sampling airborne fungi and bacteria which can be cultured. It is particularly suited for work with selective media, since aliquots of the solution of one filter can be plated out on several media. If desired, counts of non-culturable spores may be obtained by microscopic examination of the sediment obtained on centrifuging an aliquot of the solution of the filter. When the filter is used in conjunction with a small hand-operated pump, a simple, efficient and readily portable spore-trap results.

The work was performed at the Asthma and Allergy Research Unit, St. David's Hospital, Cardiff, during the tenure of a research grant from the Asthma Research Council, London. I thank Mr. H. A. Hyde and Dr. D. A. Williams for encouragement, Mr. R. H. McDowell of Alginate Industries, Ltd., for technical advice and Messrs. Courtaulds, Ltd., for supplies of calcium alginate yarn.

## A Direct Measurement of the Energy Locally Absorbed from a Gamma-Ray Beam

THE energy locally absorbed in a material exposed to γ-radiation has usually been determined indirectly from measurements with an ionization chamber, using the Bragg–Gray formula. The calculation involves the use of two quantities the values of which are not accurately known: $W$, the average energy required to produce an ion pair, and $\rho$ the ratio of the stopping powers of the material and the gas. The direct measurement of the energy absorbed presents some difficulties due to the small rise of temperature which is produced. If a dose corresponding to 300 r. is given to a sample of water, the temperature will rise by only $6{\cdot}7 \times 10^{-4}$ deg. C. However, the development of the thermally sensitive resistors known as thermistors has made possible the detection of a change of temperature of less than $10^{-5}$ deg. C.

In this laboratory a radiation calorimeter has been constructed. The sensitive part consists of a cylinder (2 cm. in diameter, 2 cm. in length) of a given material in which are imbedded a thermistor and a heating coil. The cylinder is suspended in an evacuated and aluminized glass vessel placed in a tank of water the temperature of which is controlled. To minimize the effects of heat transfer and self-heating in the thermistor, an identical dummy cylinder is suspended in another evacuated vessel but does not receive radiation. The thermistors are connected to the opposite arms of a d.c. Wheatstone bridge. A change in temperature of one of the cylinders produces an unbalanced voltage which is amplified and recorded on a self-balancing potentiometer. For calibration, a known amount of energy is dissipated in the cylinder by the heating coil. The thermistors used have a resistance of the order of 100,000 ohms and a negative temperature coefficient of − 4·7 per cent per deg. at 25° C. With the present arrangement it is possible to measure a change of temperature of $10^{-5}$ deg. C. with an accuracy better than 1 per cent.

Experiments have been carried out with absorbing cylinders of carbon and aluminium exposed to the beam from our 1,000-curie cobalt-60 unit. The dosage-rate at the position of the cylinders is about 30 r. per minute. After the energy absorption measurements, the cylinders are replaced by air-filled ionization chambers of the same material and same dimensions. The results of a number of experiments are shown in Table 1.

Table 1

| Material | $E_m$ (ergs/gm. min.) | $J_m$ (e.s.u./gm. min.) | $W\rho_m$ (erg/e.s.u.) | $\frac{(\rho_m)\text{Al}}{(\rho_m)\text{C}}$ | $W$ (eV./ion pair) |
|---|---|---|---|---|---|
| C | $2{\cdot}68 \times 10^3$ | $2{\cdot}41 \times 10^4$ | $0{\cdot}111_2 \pm 0{\cdot}0015$ | 1·000 | $33{\cdot}3 \pm 0{\cdot}5$ |
| Al | $2{\cdot}70 \times 10^3$ | $2{\cdot}75 \times 10^4$ | $0{\cdot}098 \pm 0{\cdot}001$ | 0·881 | $33{\cdot}1 \pm 0{\cdot}5$ |

The second column of Table 1 gives the values of the energy absorbed per gm. per min. and is the average of three determinations for each material. The third column shows the corresponding ionization per gm. of air per min. In the fourth column we find the ratio $E_m/J_m = W\rho_m$. Since air was used as the gas in both chambers, the ratio $(\rho_m)\text{Al}/(\rho_m)\text{C}$ can be obtained. This mass stopping-power ratio (0·881) can be compared with the values calculated from the theoretical data of Whyte[1] (0·886) and Spencer[2] (0·866). If we accept Whyte's values for $\rho_m$, we obtain the values of $W$ for air shown in the last column. The values are about 2 per cent higher than the usually accepted value of 32·5 eV./ion-pair and lower than the value of 35·0 eV./ion pair obtained by Valentine[3]. Further measurements are in progress using other materials (for example, water) and other gases.

## Mineralogy and Crystal Structure of Chamosite

THE occurrence of the hydrous ferrous silicate, chamosite, in sedimentary ironstones was described by Hallimond[1]. Later, with Harvey and Bannister[2], he concluded that chamosite differed from the iron-bearing chlorites. Brindley[3,4] examined chamosites from laterites and other sources, and concluded that they were of kaolin-type. Many of the variations in X-ray diagrams were accounted for by the existence of two kaolin-type structures, one ortho-hexagonal and one monoclinic, with simply related cell dimensions. In common with some other clay minerals, chamosite had random displacements of layers parallel to the $b$-axis of integral multiples of $b/3$, giving rise to sharp $(hkl)$ reflexions only for $k = 3n$. Brindley concluded from the presence of $(hkl)$ reflexions for $h \neq 3n$ that there were no random $a$-axis displacements of layers within a single structure, similar to the 'mistakes' in the cobalt structure of Wilson[5] and Edwards, Lipson and Wilson[6]. The pure ortho-hexagonal form was found in an iron ore from the main oolitic beds at Corby, Northamptonshire, by Brindley and Youell[7].

Many chamosites from British sedimentary ironstones have since been examined. All have proved to be of kaolin-type structure. It was clear that, while the mixture of ortho-hexagonal and monoclinic forms accounted for X-ray data from the lateritic chamosites which formed the majority of Brindley's material, there were many variations in the ironstone chamosites which still required explanation. The monoclinic kaolin structure has not been detected in any of these ironstones.

The variation was almost entirely observable in the (20$\bar{l}$) reflexions. With the exception of the (200) reflexion, which usually remained sharp, these reflexions varied from sharp lines of intensities in accord with the calculated values to weak, diffuse bands. The basal reflexions and some others remained sharp and exhibited no fading comparable with the (20$\bar{l}$) series. It seems clear that the progressive degeneration of these reflexions corresponds to 'mistakes', in Wilson's sense, of random $a/3$ displacements of layers parallel to the $a$-axis. In extreme cases of disorder, all the (20$\bar{l}$) reflexions were absent, and the powder diffraction pattern showed only those lines common to the ortho-hexagonal and monoclinic structures. This disordered chamosite may be regarded as intermediate between the two Brindley structures, the ortho-hexagonal type having no $a/3$ displacements and the monoclinic type having them between all layers.

The degree of disorder can be correlated with the source of the chamosite and its chemical composition. In the main beds of the Northamptonshire Sand Ironstone, the chamosite, here heavily contaminated with siderite, is very highly ordered. Some material gives perfect (20$\bar{l}$) reflexions, but mostly some fading and broadening occur, typically corresponding to a probability of a fault between layers of 0·05. The main seam of the Cleveland ironstone and the Marlstone ironstone from Banbury contain chamosites in which the (20$\bar{l}$) series is present although generally not as perfectly as in the Northamptonshire main bed chamosite. The chamosite–kaolinite beds of the Northampton Sand Ironstone contain a chamosite which exhibits a high degree of disorder. The Frodingham ores contain at least two types, a completely disordered structure from a chamosite mudstone, and a moderately ordered structure in siderite-rich material. The ordered chamosites are rich in iron. Disordered chamosites appear generally to contain less iron and more aluminium. The alteration of the diffraction pattern during oxidation to a ferric chamosite also corresponds to the introduction of $a$-disorder, or to the increase in $a$-disorder if already present. Both the disorder due to oxidation and that due to variation of source may have a common origin in the reduction of the mean octahedral ionic radius. Ferric chamosite formation involves a change from $Fe^{++}$ 0·83 A. to $Fe^{+++}$ 0·67 A., while passage from iron-rich to iron-poor types is accompanied by replacement of $Fe^{++}$ 0·83 A. by $Al^{+++}$ 0·57 A. It is significant that disordered chamosite is almost invariably accompanied by kaolinite, and ordered chamosite by siderite.

The continuous series from $a$-ordered chamosite to $a$-disordered chamosite may be compared with the corresponding aluminous minerals, $a$-ordered fireclay and $a$-disordered metahalloysite.

Thanks are due to Prof. G. W. Brindley for his interest in the work, and to Prof. J. H. Taylor, Dr. W. Davies and Dr. E. Cohen for specimens. A full account of this work will be published later.

## Structure in Vitreous Silicates as shown by Low-angle Scattering of X-Rays

VITREOUS substances have been characterized by wide-angle X-ray methods as random, three-dimensional networks possessing no long-range order. Some recent experiments at the lower limits of resolution of the electron microscope[1] have cast doubt on the correctness of this description and suggest that there are regions of different amounts of order in many vitreous silicates.

Since vitreous silicates are somewhat analogous structurally to amorphous organic polymers, it was believed that studies of inhomogeneities in both systems might be related. Accordingly, the low-angle X-ray technique which we use for polymeric systems was applied in a brief survey to some silicate preparations. This technique is capable of detecting inhomogeneities and long-range order below the size limitations of the electron microscope[2].

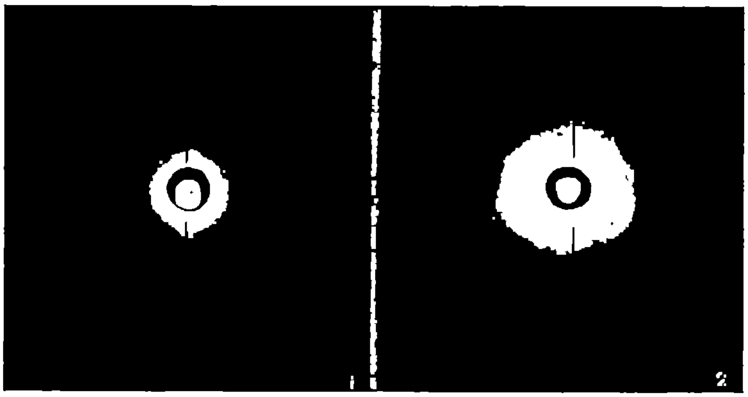

Fig. 1. Low-angle scattering from powder of $Na_2O.MgO.3SiO_2$ quenched into mercury from melt at 1,080° C. Bragg spacing of diffraction ring = 30 A. Sample-film distance = 17 cm.; Kodak 'No-Screen' film, 64-hr exposure; 0·010 in. sample thickness; copper $K\alpha$ (nickel filtered) radiation

Fig. 2. Low-angle scattering from powder of $Na_2O.MgO.3SiO_2$ slowly cooled from melt at 1,080° C. Same exposure conditions as Fig. 1

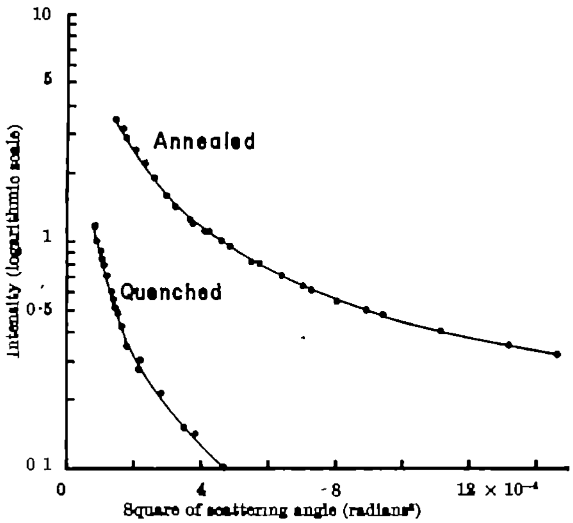

Fig. 3. Diffuse scattering from $Na_2O.MgO\ SiO_2$ powders

X-ray patterns at low angles were obtained using filtered radiation for several powdered-glass compositions subjected to a variety of thermal treatments. It was found that these patterns varied in their amount of diffuse scattering and in the presence of a discrete diffraction ring corresponding to a 30-A. spacing. To our knowledge, neither of these effects has been described for simple glasses. We feel they necessitate a revision of the random network theory of these glasses.

A molten drop of silica was captured in mercury to achieve the maximum cooling-rate; another drop was placed in a platinum crucible in a furnace set at 1,080° C. and allowed to cool slowly to room temperature, annealing it. These two samples, after grinding, produced different low-angle X-ray patterns. The chilled sample showed more intense central diffuse scattering than the slowly cooled sample. On the other hand, only the slowly cooled silica glass showed a discrete diffraction ring; the diameter of this ring corresponded to a 30-A. Bragg spacing.

The results were reversed in $Na_2O.MgO.3SiO_2$ glass. A sample was quenched from 1,080° C. in mercury and a second sample cooled slowly after being stabilized at the same temperature. Diffraction patterns of these samples are shown in Figs. 1 and 2. The diffuse scattering extended farther in the annealed than in the chilled glass, and the diffraction ring was present in the chilled, but not in the slowly cooled glass.

The curves in Fig. 3 were obtained from the densitometer traces of the diffuse scattering on the low-angle films of these $Na_2O.MgO.3SiO_2$ powders which had received the different heat treatments. A plot of logarithm of the intensity versus square of the scattering angle in radians can be used to determine the size of the scattering inhomogeneities[2]. Assuming spherical shapes, the size distributions were obtained by the method of Jellinek, Solomon and Fankuchen[3]. The observed curves were resolved into limiting straight lines which corresponded to the following sizes and fractional proportions:

Table 1

| Cooling-rate | Size and proportion of inhomogeneities |
|---|---|
| Slow | 24 A. diameter, 77 per cent of the observed scattering |
| | 78 A. ,, 23 ,, ,, ,, ,, ,, ,, |
| Fast | 68 A. ,, 55 ,, ,, ,, ,, ,, ,, |
| | 120 A. ,, 45 ,, ,, ,, ,, ,, ,, |

Since we could not record the entire amount of the diffuse scattering to zero scattering angle, these results give a relative proportion of only the smaller inhomogeneities causing the scattering.

It is known that slow cooling compacts glass[4]. The higher proportion of larger inhomogeneities in the quenched $Na_2O.MgO.3SiO_2$ glass suggests that the disorder present at the high temperature was frozen in by the sudden cooling, whereas during slow cooling these regions of low electron density became smaller. Our observation of a reversal of the effects of different cooling-rates in silica glass is supported by the fact that pure $SiO_2$ glass has opposite properties[4] and insignificant thermal contraction[5].

It is possible that the inhomogeneities causing this diffuse scattering are the same as the 'cracks' or 'flaws' proposed by Griffith[6]. He postulated the elongation of these flaws to explain the unexpectedly high strengths of highly drawn glass fibres. The low-angle pattern shown in Fig. 4 of commercial Owens-Corning 'Fiberglas' confirms the presence of inhomogeneities which are elongated in the direction of the fibre axis.

An unambiguous interpretation of the 30-A. discrete scattering cannot be made with our limited results. However, it is fairly certain to us that these diffraction maxima are evidence for a 'two-phase' or 'micellar' nature of glass, and call for a revision of the random network theory of glass.

It appears that the low-angle X-ray technique is capable of elucidating structure in an amorphous material. Since this is the extent of our interest in silicate systems, we hope the questions raised by our brief experiments will be answered by others.

## Lowered 'Capillary Resistance' after Iontophoresis of Lysergic Acid Diethylamide

There is some evidence that 5-hydroxytryptamine may be concerned in hæmostasis (reviewed by Page[1]); but it is difficult to test directly the hæmostatic effect of the drug in normal persons, because, if it has such a role, it is presumably already available in optimal concentration. An attempt was therefore made to weaken the normal hæmostatic system in man by treatment with lysergic acid diethylamide, which Gaddum, Hameed, Hathway and Stephens[2] have found to be a potent inhibitor of 5-hydroxytryptamine on the isolated rat uterus. Because of its effect on the personality, the drug could not be administered systemically. The effect of the drug was therefore investigated by measuring the 'capillary resistance' in small areas of skin which had been infiltrated by iontophoresis.

Solutions of lysergic acid diethylamide were prepared in 0·05 *M* phosphate buffer, *p*H 5·8–6·5 (depending on the solubility of the sample) at concentrations of $10^{-2}$, $10^{-3}$, $10^{-4}$ and $10^{-5}$ (calculated as base), and 0·4 ml. of a given solution was taken up in a thick blotting paper pad 2 sq. in. in area. This was placed on the skin of the anterior aspect of the arm and was made the anode of an iontophoresis circuit, following the method of Barcroft, Bonnar, Edholm and Effron[3] with adrenaline. A current of 2 m.amp. was passed for 5 min. The pad was removed and hæmostasis was tested by measuring the resistance of small vessels to reduced pressure[4]. After noting any existing petechiæ, the total number of petechiæ in the treated arm was successively recorded after reducing the pressure to 100, 150, 200, 250 and 300 mm. mercury below atmospheric. Each pressure was maintained for 30 sec. and the petechial counts were made after returning the test area to atmospheric pressure after each reduction. The symmetrically placed area of skin on the opposite arm was similarly tested after an identical treatment with buffer alone.

No personality changes were noted after these treatments, which suggests that only a small fraction of the drug contained in the pads entered the skin.

Thirty-one series of petechial counts were thus obtained from both arms (the right arm was treated with the drug in twelve tests and the left arm in nineteen tests) in four subjects (three male and one female). The effect of treatment was investigated as follows. For each arm, the petechial count was plotted against the negative pressure, and the count corresponding to – 275 mm. mercury was estimated by linear interpolation. The pressure required to give, on the opposite arm, the lower of these counts was then estimated in the same way. The difference between these pressures was taken as the response; a positive sign was attached if the higher count at – 275 mm. mercury occurred with lysergic acid diethylamide, or a negative sign if with buffer alone.

The mean responses differed significantly from zero only at the two higher doses, being (with standard error) 56·5 ± 26·3 (ten responses; $P = 0·04$) at a dose of 1/1,000, and 100·5 ± 26·3 (ten responses; $P = 0·001$) at 1/100. The slope of the regression of response on logarithm of the dose of lysergic acid diethylamide was also significant ($P = 0·01$) over all the responses. There was no evidence of a systematic difference between the responses from the two arms, from the different sites, from different subjects or from different days of testing; although the number of petechiæ appearing in the untreated skin at a given site exposed to a given fall in pressure clearly varied from subject to subject, and was higher at proximal than at distal sites.

This method of calculating the response was particularly influenced by the high counts obtained at the extreme negative pressures. Two alternative methods of calculating a response, which gave less weight to the extreme pressures, yielded similar results with regressions significant at $P = 0·06$ and 0·08.

It may thus be inferred that, after this treatment with lysergic acid diethylamide at 1/100, and perhaps at 1/1,000, a larger number of petechiæ were produced at a given site by a given fall in pressure than would otherwise have been expected. Nevertheless, in a small series of tests in one subject, no increase in bleeding time was obtained after the iontophoresis of lysergic acid diethylamide into the nail beds of the fingers: the bleeding time was measured in test and control areas under microscopic observation[5].

The present experiments therefore suggest that 5-hydroxytryptamine may at least be concerned in preserving the integrity of undivided small vessels: that is, in preventing the occurrence of purpura.

We are grateful to Dr. I. D. E. Storey for investigating the electrophoretic mobility of lysergic acid diethylamide; to Prof. J. H. Gaddum for advice and encouragement; and to Sandoz Products, Ltd., for generous supplies of lysergic acid diethylamide.

## Turbidimetric Measurement on Synchronized *Salmonella typhimurium* Cultures

Synchronization of cellular and nuclear division in *Salmonella typhimurium* populations at densities of 1–4 × $10^7$ cell/ml. has been reported previously[1,2]. Two systems for obtaining such synchronization were described, both systems employing temperature shifts between 25° and 37°. In the first system the temperature of a culture which had been growing for ten generations at 25° was raised to 37°. In the period between 5 and 10 min. following the rise in temperature, 80–90 per cent of the population underwent nuclear division as observed cytologically[3], and as inferred from the interaction of the cells with a temperate bacteriophage. On the other hand, cellular division, as measured by colony counts, was delayed for 20–25 min., at which time it took place at an increased rate, finally re-establishing the exponential growth of the culture at the normal 37° rate (see Fig. 1).

In the second system, a culture just entering the exponential phase of growth at 37° was subjected to alternating cycles of 28 min. at 25° and 8 min. at 37°. In this case synchronized cellular division was usually obtained in the third and fourth cycles, cellular division occurring during the 37° period (Fig. 2). On the basis of the interaction of the cells with a temperate phage, it was concluded that nuclear division had also been synchronized.

When these studies were reported it was believed that the two systems bore a simple relationship to one another in that the primary effect of raising the temperature was to induce nuclear division. Recent turbidimetric studies in this laboratory, while not contradicting this hypothesis, have revealed a basic difference between these two systems.

Cultures of *Salmonella typhimurium* were subjected to the two treatments described above and the increase in cell number and mass were followed by means of colony counts and turbidimetry[4] respectively. 6-ml. samples to be studied turbidimetrically were removed and mixed with 0·05 ml. of 40 per cent formalin, and read within 15 min.; identical results were obtained using the Klett–Summerson colorimeter, fitted with a No. 69 filter, and a Hilger spectrophotometer, at λ = 650 mμ.

The results obtained with the two systems are presented in Figs. 1 and 2. As may be seen in Fig. 1, following the single temperature shift from 25° to 37°, the turbidity of the culture continues to rise exponentially at the 37° rate, whereas the counts of viable cells increase at a lower rate. This results in an increase in turbidity, or mass, per cell. The single temperature shock which induces nuclear division 5–10 min. later without inducing a simultaneous cellular division is thus not sufficient to affect the synthesis of new cell material. On the other hand, repeated cycling between 25° and 37° results in a synchronization of both the turbidity increment and cell division (Fig. 2). The repeated induction of both nuclear and cellular division obtained in such an experiment leads the growth of the population to exhibit a synchronous pattern in terms of mass as well as numbers.

In the latter system the growth pattern of the population may be considered to reflect the growth characteristics of the individual cell. Results obtained with Protozoa[5], together with the data in Fig. 2, would suggest that this growth characteristic is as follows: in the normal division cycle of a single *Salmonella typhimurium* cell, cellular and nuclear division are followed by an arithmetical increase in mass, ceasing shortly before the next cell division. A full account of these experiments will be published elsewhere.

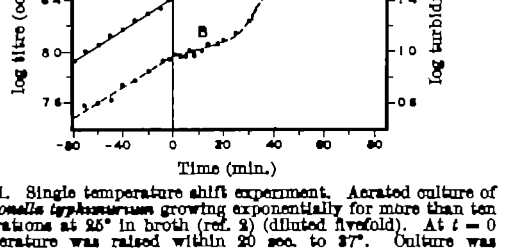

Fig. 1. Single temperature shift experiment. Aerated culture of *Salmonella typhimurium* growing exponentially for more than ten generations at 25° in broth (ref. 2) (diluted fivefold). At $t = 0$ temperature was raised within 20 sec. to 37°. Culture was diluted periodically to maintain a titre of 2–4 × 10⁷. For convenience of representation the time-scale has been doubled after $t = 0$. *A*, ●—●, turbidimetric readings in Klett colorimeter; *B*, ●---● viable titre measured as colony count. Turbidity and colony counts are corrected for culture dilutions. The normal growth-rates at 25° and 37° in broth 5 are represented by the continuous line of curve *A*

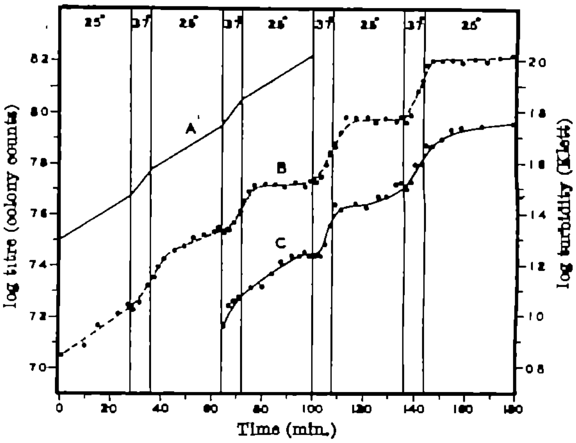

Fig. 2. Repeated temperature cycling experiment. An overnight 37° culture of *Salmonella typhimurium* was diluted 1/100 in broth 5, grown with aeration from $t = -90$ min. to $t = 0$ min. at 37°, and then subjected to alternate cycles of 25° and 37°. The hot or cold broth, added to raise or lower the temperature of the culture, maintained the titre between 2 and 4 × 10⁷ cells/ml. *A*, ——, compound exponential growth curve constructed from the normal generation times of *Salmonella typhimurium* in broth 5 at 25° and 37°; *B*, ●---●, turbidimetric reading in Klett colorimeter; *C*, ●—●, viable titre measured as colony count. Turbidity and colony counts have been corrected for culture dilutions

Two of us wish to acknowledge the support of fellowships: (V. G. B.) U.S. Public Health Service Fellow, National Cancer Institute, and (K. G. L.) Fellow of the American Cancer Society, upon recommendation of the Committee on Growth, National Research Council.

## Approximate Joint Probability Distribution for Wave Amplitude and Frequency in Random Noise

In the study of the observed properties of random noise, for example, ocean wave records, it has been pointed out by Barber[1] that, for a narrow spectrum, the probability distribution of amplitude approximates to the distribution of the wave envelope. Since the latter distribution is simple to use and gives a good fit for the higher waves, the approximation is of practical value, and has been discussed in the literature by Longuet-Higgins[2] and Watters[3].

An attempt has been made to derive an analogous formula for the joint distribution of amplitude and frequency of the main waves, neglecting small waves which occur away from the mean.

Following a suggestion made by Mr. N. F. Barber, it is possible to define the amplitude $R$ of the wave envelope as the modulus of the vector

$$v(t) = R(t) \exp i\theta(t) \qquad (1)$$

in such a way that the original noise signal is represented by the real part of $v(t)$. This definition can be shown to lead to results in accordance with those derived from the usual definition (cf. Rice[4]).

For a narrow spectrum it is reasonable to assume that the angular velocity $\theta'(t)$ will be closely related to the 'instantaneous' frequency (cf. Rice[5]) as recorded by an observer. Consequently the joint probability distribution of $R(t)$ and of $\theta'(t)$ is of interest. This joint distribution, in standard measure, is found to be :

$$2\pi^{-1/2}\, d\alpha\, ds\, s^2 \exp\left[-s^2(1+\alpha^2)\right] \qquad (2)$$

where

$$s = R/E^{1/2} \qquad (3)$$

is the 'normalized' envelope amplitude, and

$$\alpha = E\begin{vmatrix} E & -E_1 \\ E_1 & -E_2 \end{vmatrix}^{-1/2} (\theta' - |E_1|/E) \qquad (4)$$

is the 'normalized' deviation of $\theta'$ from its mean value. Here

$$E = \text{av.}\,(|v|^2),\; E_1 = \text{av.}\,(v'^{*}v),$$
$$-E_2 = \text{av.}\,(|v'|^2) \qquad (5)$$

are coefficients in the Hermitian co-variance matrix of $v(t)$ and its first time derivative.

Evidently the distribution of $\theta'(t)$ is symmetrical about the mean

$$\text{av.}\,\theta' = |E_1|/E \qquad (6)$$

and there is less scatter in $\theta'(t)$ for large values of $R(t)$ than for small. A practical inference is that it would be better, when making visual observations of ocean waves, to estimate mean frequency from the groups of high waves that occur from time to time than by measuring all the waves. A further inference is that the mean frequency of the high waves will tend to the value (6) rather than to the expected half-frequency of zeros $(-E_2/E)^{1/2}$, (Rice[6]), which results when all waves are considered.

A more detailed account of this work will be published in the *New Zealand Journal of Science and Technology*.

## Use of a Computing Machine as a Mechanical Dictionary

IN considering the application of an automatic calculator to problems of mechanical translation, the first need which arises is the storage of a dictionary[1]. It has been shown[2] that the naïve scheme in which the translation is contained in that storage location the address of which is given by the number that results from numerical encoding of the foreign-language word is not practical, and the procedure which has been adopted up to the present has been to store the dictionary in a sequence of locations. The order of storage is such that the code number of the foreign language portions of the words are in ascending order of magnitude. To select the entry corresponding to a given foreign-language word, the code number of that word is subtracted successively from the dictionary entries starting from the first. The result of such a subtraction will always be negative until the required position is reached, when the searching process is discontinued and the next phase of the translation operation is initiated.

It is evident that, for a dictionary which contains $N$ words, an average of $N/2$ subtractions will be required to locate a word chosen at random. Since $N$ may be between $10^4$ and $10^5$, and the subtraction and access times on many machines amount to about $10^{-3}$ sec., the time to locate a given word will lie between 5 and 50 sec.

To reduce this time, a possible method is to store words which start with the same letter in storage locations the code numbers of which are related to those of the initial letters. This reduces the time of search by a factor of about 26, but has the disadvantage that some blocks of locations will be only partially filled.

An alternative approach to the problem of dictionary search is as follows. For convenience it will be assumed that entries are stored in locations 1 to $N$, and the unknown word is first subtracted from the dictionary entry in location $N/2$. If the result is positive, the required entry is either that contained in position $N/2$, or it is contained in one of the locations $N/2$ to $N$. If the result of the subtraction is negative, the required entry lies in locations 1 to $(N/2 - 1)$. In the former case the comparison is repeated on the entry contained in location $(N/2 + N/4)$, and in the latter case on the entry in $(N/2 - N/4)$. This process is repeated until the unknown position is isolated.

The importance of the method lies in the very small number of comparisons which are needed to isolate an entry. Thus, for a dictionary of $10^4$ words, less than 14 comparisons will isolate any given word, and for $10^6$ words 20 comparisons should suffice. The time of search required for the example quoted earlier would thus be reduced to less than 20 m.sec.

In practical application it is not usual for $N$ to be of the form $2^m$, so that instead of the numbers $N/2$, $N/4$, . . ., etc., it is sufficient to take the nearest integer to these values.

An amusing lecture demonstration is based upon this process. A member of the audience selects a word at random from the "Concise Oxford Dictionary" ; by asking a maximum of 14 questions the lecturer is then able to find the word selected. A simple form of the question is "Does the word come before . . . ?" in the dictionary. Partition need only be approximate and a rough division of the dictionary into ½, ¼, etc., by eye is sufficient.

# FORTHCOMING EVENTS

### Monday, September 19—Friday, September 23

Fédération Internationale Pharmaceutique (at Senate House, University of London, Malet Street, London, W.C.1), at 9.30 a.m. daily—16th General Assembly.

### Tuesday, September 20—Friday, September 23

Library Association (at Southport)—Annual Conference.

### Wednesday, September 21—Thursday, September 22

Institution of Civil Engineers (at Great George Street, Westminster, London, S.W.1), at 10 a.m. daily—Conference on "The Correlation between Calculated and Observed Stresses and Displacements in Structures".

### Wednesday, September 21—Friday, September 23

Society for Water Treatment and Examination (at Newcastle-upon-Tyne)—Autumn Meeting.

### Thursday, September 22—Saturday, September 24

British Society of Rheology (at the Washington Singer Laboratories of the University College, Prince of Wales Road, Exeter)—Symposium on "Surface Rheology".

### Friday, September 23—Saturday, September 24

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1)—Symposium on "Some Recent Developments in Magnetic Materials".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Metallurgist (with an honours degree in metallurgy or A.I.M., and several years practical experience in industry and preferably some knowledge of the metallurgical problems associated with electrical power generation) in the Chief Engineer's Department, Bankside House, London, S.E.1—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting AE/660 (September 23).

Lecturer (with high qualifications in mathematics and good teaching experience) in Mathematics—The Principal, Derby Technical College, Normanton Road, Derby (September 24).

Senior Lecturer (with a good honours degree, and experience in the application of statistics, preferably in industry) in Statistical Methods, a Senior Lecturer (preferably with some industrial experience) in Mathematics, and a Lecturer (with good academic qualifications) in Mathematics—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (September 24).

Economist (with first- or second-class honours degree in economics, statistics or kindred subject, with ability to write clearly and concisely and preferably with knowledge of British agriculture and trade)—The General Secretary, National Farmers' Union, 45 Bedford Square, London, W.C.1 (September 26).

Head of the Physics Department—The Principal, Derby Technical College, Normanton Road, Derby (September 26).

Assistant Experimental Officer or Experimental Officer (graduate) in the Bee Department, for work on bee behaviour—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (September 30).

Assistant Lecturer (with an interest in, and ability to teach, theoretical physics) in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (September 30).

Lecturers (2) (with a special knowledge of one of the following fields: electrical machinery, vibration analysis and engineering acoustics, communications (other than radio)) in Electrical Engineering—The Secretary of University Court, The University, Glasgow (September 30)

Mathematicians, Scientific Officer grade (with a first- or second-class honours degree in mathematics or equivalent qualifications), at the Ministry of Supply Headquarters in London, for (*a*) to investigate data reduction associated with ballistic instrumentation, with a view to improving methods of presentation of results and to introducing methods of analysis applicable to automatic computing machines; and (*b*) for theoretical and experimental work in external ballistics, analysis of trials results and application to assessment of performance—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.331/5A (September 30).

Professor of Mechanical Engineering at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Ceylon, September 30).

Scientific Officer (with an honours degree in biochemistry or similar qualification) in the Biochemistry Department—The Secretary, Hannah Dairy Research Institute, Kirkhill, Ayr (October 3).

Principals (with a degree in engineering or equivalent, and with industrial and teaching experience) in the Gold Coast Civil Service, to take charge of Technical Institutes—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.114/12/01 (October 4).

Senior Lecturer or Lecturer in Physical Chemistry or Inorganic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 7).

Lecturer in Zoology at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Assistant Biochemist, Basic grade (with a B.Sc. degree with honours in chemistry or biochemistry or an equivalent qualification) in the Department of Pathology—The Group Secretary, Wolverhampton Hospital Group, The Royal Hospital, Wolverhampton.

Fison Research Fellow (with a good honours degree in science or agricultural science, and postgraduate experience), for work on (*a*) the role of the soil fauna in soil fertility, or (*b*) the mineral nutrition of the leguminous pasture plants—The Registrar, The University, Nottingham.

Hospital Physicist (with an honours degree in physics, and preferably with experience in hospital physics) in the Radiotherapy Department—The Secretary, Romford Group Hospital Management Committee, Oldchurch Hospital, Romford.

Lecturer (graduate of a British university, and with industrial experience) in Power Engineering—The Clerk to the Governing Body, Battersea Polytechnic, London, S.W.11.

Lecturer (with a good honours degree and research experience) in Botany, at the Imperial College of Tropical Agriculture, Trinidad, B.W.I.—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2.

Principal Scientific/Senior Scientific Officer (with a first- or second-class honours degree in chemistry or equivalent, a good general knowledge of modern research developments in lubricants and fuels, and preferably with some experience of the petroleum industry) at the Ministry of Supply Headquarters in London, for the initiation and progressing of basic research and development work, in Industry and a Ministry Laboratory, on lubricants and petroleum fuels—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.674/5A.

Research Assistants (honours graduates in chemistry, preferably with a specialized knowledge of inorganic or physical chemistry) in the Department of Applied Science—The Clerk to the Governors, Wolverhampton and Staffordshire Technical College, Wolverhampton.

Senior Chemist (with a good honours degree in organic chemistry or biochemistry, and preferably with some research experience and/or industrial experience), for work mainly concerned with various aspects of cereal chemistry, flour lipids, and the technology of baked products—The Director of Research, British Baking Industries Research Association, Chorleywood, Herts.

# UNIVERSITIES AND ACADEMIC FREEDOM

PROBABLY the most outstanding feature of university developments in Great Britain in the post-war years is the extent to which both old and new universities have become dependent on State assistance. Whereas in 1920–21 only some 33 per cent of their funds came directly from the Treasury and 12 per cent from local authorities, in 1953–54 no less than 70·5 per cent of their recurrent income came from Parliamentary grants, and 3·6 per cent from local authority grants. Moreover, the proportion of students holding scholarships or some form of award from public or private funds has risen from 45 per cent in 1928–29 to some 71·9 per cent in 1953–54, and these proportions are increasing. At the same time, over the past ten years the universities have drawn from the State practically all the funds for large-scale capital development, instead of, as previously, having to find such funds from endowments or through local effort. While the proportionate financial dependence of the universities on the State has thus increased, the share of the national resources which goes to the universities has also increased very greatly. In 1920–21 the income of the universities in Britain was about £3 million, but in 1953–54 it exceeded £31 million, and the expenditure per student averaged nearly £400 instead of about £75.

This growing dependence of the universities on the State is one reason for the recurrence of discussions on academic independence and autonomy at almost every gathering of university bodies, whether at the Conferences of the Home Universities, at the Congress of Universities of the Commonwealth, or at the Conference of the Universities of Western Europe held in Cambridge last July. Friendly observers from the United States at the Commonwealth Congress and in an earlier book, "Government Assistance to Universities in Great Britain" (see *Nature*, 171, 273; 1953), have openly expressed their doubts as to the universities of Britain being able to preserve their traditional independence. Notwithstanding the reassurances on this point given by successive Chancellors of the Exchequer, and the way in which the Treasury has hitherto consistently rejected proposals from the Committee on Public Accounts or the Select Committee on Estimates for methods of financial control which appear to endanger that autonomy, there is clearly apprehension on the subject within the universities themselves.

To such misgivings Sir Hector Hetherington gave frank expression in his P. J. Anderson Memorial Lecture to the University of Aberdeen last November[*]. Looking at the increasingly continuous and closer government and parliamentary intervention in university affairs, he displayed the reasons for this livelier interest and the agencies by which the present situation has been reached. Factually he concerned himself more particularly with the Scottish universities; but nevertheless his lecture is a most penetrating and critical survey of the British university system as a whole over the past forty years.

Sir Hector brings out at the start two interesting points. He does not expect government policy to achieve its declared objective of doubling the pre-war student numbers by about 1956, and suggests that the present increase of about 66 per cent may exaggerate the effective inflow of new students. The entry of graduating students, he notes, increased between 1938 and 1952 by only 55 per cent. Secondly, he notes that in Scotland, but not in England, there has been some quantitative shift away from the arts, and qualitatively too, as regards Glasgow, there is evidence that more of the abler students are studying science and medicine. The Scottish universities, drawing primarily on a home population of 10 per cent of that of Great Britain, contain 17·5 per cent of the university students, and while they contribute 13 per cent of all students in pure science, in medicine they provide 23 per cent, in technology 21 per cent, in agriculture 22 per cent, and in veterinary science 38 per cent. This response of the universities to the needs and challenges of a changed world has, he points out, been effected largely by the influence of government and public opinion, exercised, for example, through the royal commissions, of which at least six universities have been the subject in the past forty years, and the various committees, to which such names as Goodenough, Hankey, Barlow, Clapham, Scarborough, Teviot and Loveday are attached, that have surveyed different phases of university activity. Each university, moreover, is now normally closely in touch with half-a-dozen major Ministries, the needs and policies of which are reflected in its own work. Again, there are inter-relationships with the Department of Scientific and Industrial Research and the research stations and research associations sponsored by that Department, as well as with the other research councils concerned with medicine and agriculture.

Sir Hector does not pursue in any detail the relations of universities to the national organization for research in pure and applied science. He recognizes that they form an essential part of that structure and while, from a passing reference to the Atomic Energy Authority, he is aware of the dangers of sponsored research or of such devices as the earmarked grant, he is content to leave their implications to be considered in the light of the general principles which he lays down. Prof. W. H. G. Armytage in his "Civic University"[*] has to some extent rectified this omission. In this connexion he refers pointedly to the extent to which the Advisory Council on Scientific Policy is concerned with university development from the point of view of scientific research as well as from that of education.

---

[*] The British University System 1914–1954. By Sir Hector Hetherington. (P. J. Anderson Memorial Lecture, 1954. Aberdeen University Studies, No. 33.) Pp. 13. (Edinburgh and London: Oliver and Boyd, Ltd., 1955.) 1s.

[*] Civic University: Aspects of a British Tradition. By W. H. G. Armytage. Pp. 328+8 plates. (London: Ernest Benn, Ltd., 1955.) 30s. net.

Both Prof. Armytage and Sir Hector Hetherington, in reviewing the development of the University Grants Committee over its first twenty-five years, stress the revised terms of reference, which in 1946 placed on the Committee, besides the responsibility for advising on the financial needs of the universities and the distribution of the sums voted by Parliament, the functions of collecting and making available information about British universities and of assisting "in consultation with the universities and other bodies concerned the preparation and execution of such plans for the development of the universities as may from time to time be required in order to ensure that they are fully adequate to national needs". Both again recognize that this implies the possibility of planned expansion under government rather than local initiative, and a definite move towards the development of a national system of university education. Both recognize that it was inevitable that this large responsibility should be laid upon the University Grants Committee, and that the time had come when the Government was bound to assure itself that somewhere in the university system provision was made for every field of learning which is necessary to the national interest. Nor do they suggest that this is not the right way to achieve that purpose.

Whereas, however, Prof. Armytage's analysis of the situation is concerned rather with the professional aspects and the ability of the universities to meet the needs of Britain for vocational education at that level and for research institutions, Sir Hector probes further into the working of the system, and emphasizes the special relation of the universities to the Treasury. With other Departments and organizations, the relations are those of collaborators, competitors or consumers in one or other form, and influence, though important, is indirect. With the Treasury, however, the relation is continuous, and, but for the intermediary University Grants Committee, direct. In so far as there is a Minister answerable in Parliament for the universities of Britain, it is neither the Minister of Education nor the Lord President of the Council but the Chancellor of the Exchequer; and by one of those curious touches of the British constitution, the Minister who watches most closely over the expenditure of other Ministers has in the universities a little spending department of his own, the autonomy of which he has in recent years stoutly defended in Parliament.

In discussing the implications of this situation, Prof. Armytage and Sir Hector are again complementary. The former, in considering the ways in which pressure may be brought to bear on the universities in the direction of vocational studies, sponsored research or the detailed control of expenditure, directs attention to certain intangible assets in the community which help the universities to resist such pressures. Against, for example, extreme calls for an externally imposed planned system of university education, the British universities can count on the fact that the limited size of the university population in the country greatly restricts the area of popular interest in the universities and the possible political pressures which could thus arise. This is reinforced by the fact that the universities are still severely professional, as can be seen in the persistent prejudices against the employment of university graduates in positions for which the changed educational pattern has greatly reduced the chances of recruiting the necessary talent in other ways. Still more potent is the sympathetic relationship between the universities, the University Grants Committee and the Treasury departments, which arises from the common outlook and origins of their personnel. That community of outlook and interests not only promotes co-operation but also an understanding that ensures that proposals which threaten to disturb the traditional autonomy of the universities will require to demonstrate a very clear public advantage if they are to pass the scrutiny even of the Government side.

Sir Hector takes this for granted. He examines rather the way British universities have drawn together—not so much deliberately in self-defence—for example, by joint consultation between an impressive range of specialist societies in which scholars and scientists take counsel about their several studies and the policies by which those studies may be advanced, or between less formal groups within and without the universities. He notes, too, the way in which circumstances have forced such a body as the Committee of Vice-Chancellors and Principals not merely to consider matters of common interest to the universities, but also to make commitments for the universities and to influence significantly university and even government policy; and he notes also the way in which university individualism is further circumscribed by external influences, even in regard to rates of pay.

Sir Hector is concerned rather to show how the Committee of Vice-Chancellors and Principals has come, somewhat against the wishes of its members, to function as it does as a body to the views of which both university courts and government departments attend with some care, notwithstanding that the Committee neither possesses nor desires executive authority. In his judgment something of the sort must have been created during the past twenty years if it had not already existed. But while he admits that, in this and in other ways, we have come a good deal nearer a university system, and that government influence is strong, Sir Hector gives no support to the idea canvassed during and since the War by, for example, the British Association Committee on Post-War University Education, the Parliamentary and Scientific Committee and the Association of University Teachers, for a fully representative Universities' Advisory Council. By implication rather than explicit statement, he suggests that the universities' defences are still sufficiently strong and that the existing organization provides effective means for formulating common policy where desirable, or on the other hand for representing common views to the Government.

Sir Hector's chief concern appears to be that British university structure may become too rigid in its internal and informal aspects, and that a certain consequential change of mood may be detrimental to the outlook and to the spirit of adventure in which a university does its best work. A university is a living corporation or society—not an institution—the members of which are bound together to promote sound learning and the advancement of knowledge, to follow inquiry wherever it leads. If the growth of organization confuses that issue and leads to disregard of the freedoms essential for such a community or even to uncertainty as to their nature, university independence is endangered, no matter how carefully the Government itself may respect the right and duty of the university for final decision as to the organization of its courses and for the character and standards of the instruction given within its walls.

Sir Hector is not blind to the dangers of the present situation and trends. He recognizes that an unlucky appointment in any one of three or four key posts could easily work great mischief. He acknowledges that Parliament can rightly expect of the universities an account of their expenditure of the large sums of money they now receive, and that the universities should be ready to listen to criticisms of their activities. He recognizes, too, that this is an essential part of the task of building up an instructed public opinion and that, in the last resort, this is the only defence of the universities, though to him the pervasive influence of the mass mind seems to be a less formidable menace than it appeared to be to Sir Walter Moberly.

The next decade will show whether or not Sir Hector is too optimistic in this respect, but the evidence would suggest that the mass mind is a more formidable menace than when Sir Walter Moberly wrote six years or more ago, and that it would be unwise to rely unduly on the level of enlightenment in government circles. Indeed, there is already evidence of surrender on the part of the Ministry of Education to sectional pressures, and it could well be that the real threat to the full responsibility of the universities in academic affairs may in future come not from the Chancellor of the Exchequer or the Lord President of the Council, but from the Minister of Education, in spite of the absence of any formal responsibility on his part for the universities. Unless, indeed, educational policy as a whole is shaped with clear conceptions as to the purpose and functions of a university and of the over-riding importance of quality rather than numbers, decisions may be taken elsewhere which adversely affect the work of the universities or the resources at their disposal.

The education of public opinion as to the work of the universities and their essential place in the community thus involves much more than the purely factual accounting to Parliament or public opinion generally for the expenditure of the funds received from public sources. It means that the purpose and nature of a university should be widely and clearly understood, and also the way in which a university works and the vital relation of academic freedom to the achievement of its purposes and the service it renders to the community. It is not enough that this should be understood in government departments or in Parliament, though this is essential if plans for university expansion and for the development of technological or technical education are to be conceived soundly and kept in balance with national needs and resources. It means that, as Dr. Eric Ashby emphasized in a broadcast talk early this year on the British universities, a determined effort must be made to enlighten the man in the street, who is now the effective patron of the universities. The real threat to academic freedom is from public ignorance of what the universities are and what they are doing. The continuance of the effective functioning of the British university system depends in large measure on the extent to which the universities themselves and their alumni, whether in government office or department, in industry or in public or private life, seek and use every opportunity in Parliament, in the schools, in adult education and other extra-mural work and in every possible way to interpret to the public the purpose and method of university life and work.

# BABYLONIAN ASTRONOMY

### Astronomical Cuneiform Texts

Babylonian Ephemerides of the Seleucid Period for the Motion of the Sun, the Moon, and the Planets. Edited by O. Neugebauer. Vol. 1: Introduction, The Moon. Pp. xvi+278. Vol. 2: The Planets. Indices. Pp. xii+279–512. Vol. 3: Plates. Pp. v+255. (London: Percy Lund Humphries and Co., Ltd. Published for the Institute for Advanced Study, Princeton, New Jersey, U.S.A.) 105*s*. the set.

THE publication of these three volumes, containing the source material of our present knowledge of Babylonian astronomy, has placed all students of the history of mathematics and astronomy under a deep obligation to Prof. O. Neugebauer, whose earlier work, "The Exact Sciences in Antiquity" (1951), contains a brief summary (see *Nature*, 169, 854; 1952).

In the first of the two clearly marked periods in Babylonian science—the Old Babylonian, *c*. 1800–1600 B.C.—mathematics reached a high level, but astronomical knowledge was crude and merely qualitative. One group of documents contains the earliest records of actual observations in Mesopotamia. For several years the appearances and disappearances of the planet Venus were recorded, the dates being given in the contemporary lunar calendar, and have proved useful in determining the chronology of the Hammurapi period. Two texts dating from about 700 B.C., but undoubtedly based on older material, contain a summary of the astronomical knowledge of the day. One is concerned mainly with the fixed stars arranged in three 'roads', of which the middle one is an equatorial belt of about thirty degrees in width. The other deals with the Moon, the planets, the seasons, shadow-lengths and other related phenomena.

In the second period—the Seleucid—which is datable to the last three centuries B.C., the introduction of a sign for zero led to a complete mastery of arithmetical calculations immediately available for application to the problems of astronomy. The predominantly mathematical character of Babylonian astronomy was not realized by early investigators, who stressed the observational side and failed to appreciate the difficulties of observations near the horizon in areas subject to desert sand-storms. It is a remarkable fact that not a single text of this period can be called wholly observational.

The most important step in the development of scientific astronomy was the adoption of the ecliptic (the apparent path of the Sun among the fixed stars in the course of the year) as a reference-line for all lunar and planetary phenomena—perhaps as early as 500 B.C. The calendar in use was essentially lunar. The day began in the evening (cf. *Genesis*, i, 13) and the month began on the evening of the day of first visibility of the new crescent Moon shortly after sunset. To predict this day accurately was the primary concern of the early astronomers, but the real problem for them was to fix the exact moment of conjunction of the Sun and Moon. The Babylonians solved it by considering the velocities of the Sun and Moon and their variations. How this scheme was evolved we do not know. We meet with it already fully developed in the "Ephemerides" and "Procedure Texts", more than three hundred of which have now been published in the volumes under consideration.

The "Ephemerides" are tables showing the position of the Sun, Moon and planets computed for regular time-intervals, comparable with those in our modern "Nautical Almanac", and used to predict the times of astronomical phenomena. Most of these tables were carefully written out in columns with details such as the date, the velocities of the Sun and Moon, and the various corrections required by the computer. On some tablets we find details frequently computed for several years in advance. The so-called "Procedure Texts" give rules for determining an ephemeris step by step. The tables are 'final copies', omitting intermediate steps in the calculations, and some of the columns give only the rounded-off values. These methods of computing lunar and planetary phenomena were certainly in use *c.* 250 B.C. Two slightly differing variants of the lunar theory were in use. One assumed the Sun to move with constant velocities on two complementary arcs of the ecliptic; the other assumed a linear zig-zag function for the Sun's velocity as a function of the time. The results are amazingly good and could scarcely be improved upon with elementary mathematics. The determination of eclipses was not so successful, since parallax of both the Sun and the Moon was completely disregarded. The Babylonian procedure shows a remarkably abstract attitude and unhesitatingly introduces quantities for purely mathematical convenience on the same principle as complex numbers are employed in modern mechanics.

Planetary theory was not developed to the same degree as that of the Moon. The method of time reckoning was independent of the civil calendar and was based on a special unit, the one-thirtieth of a lunar month, corresponding to the Hindu *tithi*. The use of this unit implies that the accuracy aimed at was less than that considered necessary in the case of the lunar theory. Several different systems were used, and interpolation schemes were ingeniously devised and skilfully applied to describe the daily motion of the planets.

We derive little of our knowledge of Babylonian astronomy from Greek sources. Pliny mentions the existence of astronomical schools at Uruk, Babylon and Sippar. Ptolemy refers to lists of eclipses dating back to 747 B.C. and complains of the lack in Babylonia of reliable planetary observations—a very fair estimate of the position.

Among units used, it is interesting to find the 'barleycorn' (the 1/180 part of a larger unit) used for the latitude. The degree was the fundamental unit for measurement of arc as it was for time. The day was divided into six parts, each divided again sexagesimally. This system was transferred to the sky and survives in our modern reckoning of right ascension and time. Water clocks were employed in connexion with measurements of the daily increase or decrease in the length of daylight or night.

The main incentive for the study of astronomy seems to have been the attempt to introduce some measure of regularity in the intercalations of the lunar calendar. Astronomy did not originate in astrology as has so often been stated; but the very widespread belief in astrology as the one science which gave insight into the causes of events on earth influenced the transmission of astronomical knowledge from one nation to another. The technique of Hellenistic astrology demanded knowledge of the position of the Sun, Moon and planets in the zodiacal signs at the moment under consideration, and this information was not immediately available from the Babylonian ephemerides, of which the elements played no part whatever in the practice of astrology. Magic, number-mysticism and astrology can no longer be regarded as the guiding forces in Babylonian science.

The texts considered in this new publication represent but a small fraction of the total available, most of which still remain unexamined. Few scholars are as competent as Prof. Neugebauer to deal with these, and perhaps in time he may be able to throw some light on the interesting problem of how the methods of computation were arrived at—quite possibly in a relatively short period, by some Newton or Einstein of the day. The three volumes are admirably printed, of handy size and include a full bibliography, a useful concordance of texts, glossaries and index.

R. W. Sloley

# BIOLOGY IN SCHOOLS

**The Teaching and Learning of Biology in Secondary Schools, with Special Reference to Grammar Schools**

By Prof. L. T. Green. Second, revised edition. Pp. ix+248+6 plates. (London: Allman and Son (Publishers), Ltd., 1955.) 12*s.* 6*d.* net.

THIS new edition of Prof. L. T. Green's book is timely and useful. The author combines theory and practice in a skilful manner. Most books on science teaching neglect the problems of learning as distinct from those of teaching. There is a considerable bulk of research papers on science teaching, and these are relatively inaccessible to most teachers. There is, as Prof. Green remarks, a curious British tradition that objective techniques cannot be applied to educational problems. Nevertheless, he has made a careful digest of all such work relevant to his book, and the documentation is complete.

Prof. Green writes that the two generally accepted points in biology teaching are: first, that the study of biological science in schools should present a picture of biology as a whole and not consist of two quite separate courses of botany and zoology; secondly, that biology should be studied in terms of its general principles and functional aspects. Generally speaking, the universities do not know biology as a subject and maintain a rigid distinction between its several divisions. This has influenced the work of grammar schools and in general has rendered general science courses in schools an unsafe preparation for the university award and entrance examinations.

Prof. Green is an enthusiastic and efficient photographer, and this is reflected in his book. Every useful method of producing visual material, including models and their use in the work of teaching, is dealt with in a thorough and practical manner.

The author has examined the whole field, and while he makes a plea for a wider public attention to the problems of human biology, particularly in relation to population changes and family life, he is prepared to show how the best can be got from the more formal botany and zoology. There are chapters on museums and gardens, agricultural and economic botany, sylviculture, ecology, dissection, evolution, physiology and sex education.

The recent British Association report, "Biological Sciences in British Schools", is an important and realistic but rather depressing document. It stresses "the alarming deterioration in Biology teaching in schools". There are difficulties due to large classes, lack of laboratory assistance and teachers inadequate both in numbers and qualifications. There is also the widespread neglect of field-work at all levels in many schools. The teacher must have an interest in, and knowledge of, natural history and an ecological approach to the subject. Good biology teaching and, indeed, good science teaching in all its branches, are more than ever necessary at the present time; and the pressing problems concerning the provision of adequate human and material facilities for this work must be a first priority in national schemes, not only in education but in the field of economics also.

The book is not only a safe guide for the young teacher but will, in addition, stimulate and encourage the practised worker. It is a very valuable contribution to a subject of primary importance.

W. L. Sumner

## THE GREAT BARRIER REEF

### The Romance of the Great Barrier Reef

By Frank Reid. Pp. xiii+191. (Sydney and London: Angus and Robertson, Ltd., 1954.) 18*s*.

ANYONE interested in Australia will be glad to have this book, especially if, like the reviewer, he knows the Barrier Reef waters. It is not in any sense a scientific work—and for that reason may be somewhat out of the ordinary run of books noted in *Nature*. It consists of twenty-six chapters of murder, piracy, cannibalism, escapes, 'blackbirding', wrecks, storms, and everything that goes to make the successful adventure book. The difference is that all these incidents are vouched for, and the sum total of frightfulness is far worse than any ordinary tale. It is, indeed, an example of fact being stranger than fiction.

Frank Reid is well known in Australia and he has collected the material in this book very largely from people who took part in the adventures, or were at any rate very closely concerned with them. The earlier events are based on historical records, and A. W. L. Russell, who was for some years honorary secretary of the Queensland Royal Geographical Society, states in his foreword, and the author in his preface, that all the events related, fantastic though some of them may be, are entirely factual. Many of them relate to the islands in Torres Straits—one of the most dangerous pieces of water in the world. Several others are based on the Palm Islands—now a large native reserve.

Apart from man's brutality, the book does bring out very clearly indeed the dangers of navigation in reef waters. Great care is always necessary, and it is difficult now to appreciate the dangers that Cook and his successors overcame in vessels which were entirely dependent upon wind and current. Anyone who has been to Lizard Island and seen the line of the outer barrier, the passes, the breakers, and the innumerable inner reefs gains a far greater respect for those who sailed the sea before the advent of power than can possibly be obtained from reading, however vivid the accounts may be.

To all who now travel in these waters, and especially to those who visit them in good weather for a holiday, I would recommend this book. Those who sail regularly in these waters, and those who have worked there scientifically and otherwise, will want to read it. I think one or two chapters might be added to a further edition to include the scientific 'romance' of the reefs. While it may be commended to all, I cannot but think its title should have been "The Tragedy of the Great Barrier Reef".

J. A. Steers

## MECHANICAL PROPERTIES OF METALS

### Strength and Resistance of Metals

By Prof. John M. Lessells. Pp. xiv+450. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1954.) 80*s*. net.

THIS book, which is primarily directed to engineers, covers that field, within the purlieus of engineering and metallurgy, concerned with the resistance of metals to deformation and fracture. Here, the theory of elasticity, which frequently masquerades under the misnomer 'strength of materials', has a limited application, and considerations of plasticity and fracture are essential for a complete description of the behaviour which is observed in practice. The tenuous understanding of these factors at the turn of the century precipitated an experimental approach in which such properties as hardness and notched-bar value were measured to assess the suitability of a metal for a particular engineering application. In this development little regard was paid to the real meaning of the tests; but the metallurgical engineer to-day feels that information of fundamental significance is implicit in the copious legacy of these mechanical test results which have been handed down to him. This suspicion receives support from recent progress in the understanding of plastic flow and fracture, and the time is now ripe to incorporate some of these ideas in text-books on 'mechanical testing', which too often concern themselves almost exclusively with standardized testing procedure and results. Although the efforts of the author of the book under review are a welcome step in this direction, it must be admitted that he could have availed himself more fully of the opportunity to fill this palpable gap in the literature.

The observational features of tensile, hardness, notched bar, wear, hysteresis and fatigue testing are well presented, with a text liberally garnished with tables of typical results by way of illustration. Fatigue, which is clearly close to the author's heart, receives a particularly generous coverage. A commendable feature is a chapter on the effects of overstrain in the early part of the tensile stress – strain curve, which, although known for at least fifty years, seldom finds its way into books of this kind. A realistic preference for proof stress rather than elastic limit permeates the text, along with a recognition of the importance of hysteresis. Those interested to learn more about the neglected factor of spurious energy loss in notched-bar testing, to which the author properly directs attention, would do well to consult reference 1, which is given on p. 287 for a different purpose.

The substantial section devoted to engineering resilience calculations, in the chapter on impact tests, appears a little out of place in this work, and the inclusion of notched-bar tests under the same general heading is misleading in view of the secondary importance of the rate of deformation here. In the interspersed sections of the text on interpretation of the tests, the author does not always get completely to grips with the problems. For example, no mention is made of Tabor's illuminating, but admittedly approximate, application of plane strain plasticity to the analysis of the hardness test; and the treatment of the yield point in iron and its associated recovery from overstrain would make more convincing reading if related to Cottrell's basically simple picture of solute atom migration.

Briefly, the book, which is handsomely printed and illustrated, gives a competent account of the experimental features of the mechanical properties of metals, but the senior and graduate student to whom the work is commended in the preface will probably find its attempts at interpretation inadequately stimulating.
K. M. ENTWISTLE

# GEOLOGY OF THE ICE AGE

## Das Eiszeitalter

Grundlinien einer Geologie des Quartärs. Von Dr. Paul Woldstedt. Erster Band: Die Allgemeinen Erscheinungen des Eiszeitalters. Zweite, völlig neu bearbeitete Auflage. Pp. vii+374. (Stuttgart: Ferdinand Enke Verlag, 1954.) 41 D. marks.

THE study of Pleistocene deposits is often more difficult than that of some older rocks because of the diversity of facies which is found. In dating Pleistocene beds it is therefore safer, where possible, to rely on more than one kind of 'zonal fossil'. In the present volume, as in past work, Prof. P. Woldstedt has proved himself to be a believer in this principle and shows an admirable all-round approach to the problems of the Ice Age. I understand from a statement at the end of the first chapter that this is only the first volume of a more comprehensive work and that a second is to be written dealing with separate regions.

After one introductory chapter, Chapters 2–9 are devoted to comparative glaciology: a full description is given of the world's existing ice-sheets, and depositional forms, including various kinds of moraines, outwash gravels and loess, as well as the processes of erosion, are discussed as effects of the Pleistocene ice-sheets. Interesting details are also given of the work by Milthers and others on the erratics carried by the various Baltic glaciers. The author's treatment of these subjects is in harmony with his long experience in the field, and the illustrations, some of which are exceptionally clear, are partly from his own photographs.

Prof. Woldstedt then turns his attention to fossil plants and animals, dealing at some length with the interglacial plant beds (Chapter 12) and tracing the evolution of the flora through the succession from the Reuverian up to the Holocene. Pollen diagrams are shown for the Cromer Forest Bed, which is considered to be Pre-Elster, also for the Elster–Saale and Last Interglacials in Northern and Central Europe, with detailed descriptions of the forest histories. No attention is paid to the plant remains at Hoxne, but now that this site has been freshly described by West and Donner, presumably it will be included in the forthcoming second volume. Examples are also given (Chapter 10) of marine interglacial deposits. The Eem marine beds of Holland and Germany are placed in the Last Interglacial, and the earlier Holstein deposits in the Elster–Saale Interglacial; and in Table 1, p. 215, the Holstein horizon is correlated with the Tyrrhenian, and the Eem with the Monastirian. This table summarizes the author's ideas on long-distance correlations and emphasizes a major problem which has been evident in his earlier publications, namely, the difficulty of fitting in the three known glaciations of Northern Germany with the four (or five) recognized elsewhere.

Chapters 13 and 14 then summarize the kinds of fossil man and his implements, maintaining that the Heidelberg jaw and the earliest *Pithecanthropus* remains belong to the Gunz-Mindel Interglacial, and Peking man is placed with the Swanscombe and Steinheim fossils in the Mindel-Riss stage. The Fontéchevade and Ehringsdorf remains are placed with the Neanderthal man in the Last Interglacial. Dating of the Palaeolithic implements is conventionally related to the Alpine glacial sequence.

The last three chapters (15–17) are given up to the problems of isostatic and eustatic changes of level, to a discussion of changes of climate and finally to a summary of the theories which have been formed to account for these changes. The theoretical aspect of these questions is sometimes overstressed, as in the discussion of eustatic changes of sea-level, and Fig. 121 on p. 294 represents these changes according to an ideal which does not entirely agree with the facts discovered by Gignoux, Deperet and later workers; for example, the Sicilian stage is placed in an interglacial episode in spite of the fact that it has a notably cold fauna. Apart from some of these details, most interesting climatic reconstructions are attempted, one of the most successful showing the position of the ice-sheets, tree-line and temperate forests during the Last Glaciation (Fig. 129, p. 320). The discussion of the causes of climatic change is very detailed.

The list of references at the end is comprehensive, considering the complexity of the subject, but certain omissions will perhaps be put right in the next volume; the main work of James Geikie, F. W. Harmer and Prof. P. G. H. Boswell, for example, receives little or no attention. In general, however, this book is particularly well indexed and is a most useful and well-balanced introduction to a very intricate subject.
D. F. W. BADEN-POWELL

## Thunderstorm Electricity

Edited by Horace R. Byers. Pp. viii + 344. (Chicago: University of Chicago Press; London: Cambridge University Press, 1953.) 45*s*. net.

THE volume under review is a compendium based on contributions to a conference held in Chicago in 1950, some of which have been brought up to date, together with a few chapters from other workers. The chapters deal in turn with general results of atmospheric electricity, thunderstorm dynamics, cloud physics and charge generation, followed by chapters dealing more directly with thunderstorm electricity and finishing with lightning and its effects on aircraft and power lines. As a collection of separate contributions, the book naturally suffers from a lack of coherence, and as a volume on "Thunderstorm Electricity" it may be criticized in that a great many of the chapters are not directly connected with that subject, but contain background information; for example, in the longest chapter, Chapter 5, by H. Weickmann, a mere three pages out of seventy-three are concerned with electrical phenomena.

But every chapter is of considerable interest to those whose work is at all connected with thunderstorms, though the chapters themselves are uneven in content: for example, Chapter 3, by L. Koenigsfeld, describes new work, perhaps more suitable for publication in a journal than in such a volume; Chapter 8, by R. Gunn, is a useful summary of his previously published work; and Chapter 14, by H. Norinder, combines a historical survey with an account of recent work.

The volume is attractively produced, and the large numbers of diagrams and plates are very clear. The nature of the volume has made cross-references impossible, but an index would have greatly added to its value.

J. ALAN CHALMERS

## Infinite Abelian Groups

By Irving Kaplansky. (University of Michigan Publications in Mathematics—No. 2.) Pp. v + 91. (Ann Arbor: University of Michigan Press; London: Oxford University Press, 1954.) 16*s*. net.

A REMARKABLE amount of material has been compressed into this monograph. After some examples of Abelian groups, definitions follow, together with some properties, of torsion groups and divisible groups. Then pure subgroups (*Servanzuntergruppe*) and groups of bounded order are studied, and the important notion of height is introduced. This leads up to Ulm's theorem, which, involving both cardinal and ordinal numbers, gives a complete classification of countable torsion groups. The next part is concerned with the extension of preceding results to modules over principal ideal rings and an application to the theory of linear transformations. Then the ring is restricted to a discrete valuation ring $R$, and a study is made of a complete $R$-module (that is, complete in its $p$-adic topology). A partial classification of the submodules of a given module is made in terms of the characteristic submodules, and the account ends with a review of recent literature.

The material presented is part of a course of lectures given in 1950 in the University of Chicago. Prof. I. Kaplansky has a crisp, vivid style, and a pleasant feature is the interruption of the text at various points to ask a pertinent question such as "What is our goal in studying Abelian groups?", or "How do we know when we have a satisfactory theorem?". The general atmosphere of the book is one of freshness and vigour, and the reader has the satisfaction of knowing that he is being led right up to the edge of our knowledge of a branch of modern infinite algebra.

L. S. GODDARD

## Applied X-rays

By Prof. George L. Clark. Fourth edition. (International Series in Pure and Applied Physics.) Pp. ix + 843. (London: McGraw-Hill Publishing Company, Ltd., 1955.) 89*s*. 6*d*.

THE previous edition of this book—one of the McGraw-Hill International Series—was published thirteen years ago. In that time a great deal of development has taken place in the application of X-rays to almost all branches of science, and the attempt to cover all these applications has produced a work that is generally unsatisfactory.

It must now be accepted that the subject of X-rays and their applications is too large to be covered by a single text-book, and the present book can only be regarded as a rather poor patchwork; it covers instrumentation, radiography, biological applications, X-ray diffraction and crystal chemistry. The author seems at his best in the earlier sections, the later sections being much too condensed and not distinguished by any originality of the point of view.

The presentation of much of the material seems hurried and careless. Several tables are reproduced from other works, sometimes without adequate explanation, sometimes with mistakes, and sometimes without acknowledgment. There are numerous mis-spellings of names in the references, and there is no author index. Altogether, the book must be regarded as a rather unworthy companion to the other members of this important series. Finally, I would like to ask why, in general, American books are printed on such heavy paper; this one weighs 3 lb. and is most uncomfortable to handle for prolonged periods.

H. LIPSON

## Organic Syntheses—Collective Volume 3

Edited by E. C. Horning. (A Revised edition of Annual Volumes 20–29.) Pp. x + 890. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1955.) 120*s*. net.

THIS work, begun as an annual publication in 1921 under the original editorship of Prof. Roger Adams, has proved from the first to be a practical aid of very high value to students and research workers in organic chemistry and biochemistry. It is a thoroughly reliable, accurate and comprehensive *vade mecum* for all who are actively engaged in these great and expanding fields of science. It was a happy thought of the editors to issue a collective volume at intervals, and the third volume of this kind includes the classified and revised material of annual Vols. 20–29.

In all, particulars are here given for the preparation of more than three hundred and fifty organic compounds and reagents, and there are details of new procedures for acenaphthenequinone, aminoacetal, α-tetralone, and several other substances. References have been brought up to date and linked with *Chemical Abstracts* in order to facilitate a complete search of the literature. The vast amount of material in the book has been made readily accessible by means of indexes of reactions, types of compounds, formulæ, solvents and reagents, and illustrations, in addition to a comprehensive general index. Altogether, this collective volume, like its two predecessors, is a time-saver of the first order.

JOHN READ

# PEACEFUL USES OF ATOMIC ENERGY

## CHEMICAL, METALLURGICAL AND GENERAL TECHNOLOGICAL SESSIONS AT GENEVA

By DR. R. SPENCE, C.B.

THE economic aspects and engineering design of nuclear power reactors naturally provided the main theme for the recent Conference on the Peaceful Uses of Atomic Energy held in Geneva; the supporting sciences and technologies were, however, adequately represented in parallel sessions which commenced on August 11 and finished on August 20. The *A* Sessions were mainly devoted to physics and reactor engineering; raw materials, chemistry, chemical technology, metallurgy and waste disposal problems were discussed in the *B* Sessions, while the *C* Sessions were concerned with medical and biological problems and with applications of radioisotopes.

Until quite recently, it would not have been possible to hold useful international discussions on some of these topics, but the situation has changed so rapidly during the past few months that the United States, Great Britain and Canada have been able to release a very substantial amount of technical information. The complete success of the Conference was assured when it also became known that there would be important contributions from the U.S.S.R. Undoubtedly, the greatest mass of information, in practically all fields, was supplied by the United States, and many very comprehensive survey papers were included. There were about as many Russian contributions as British, but they were not so evenly spread; for example, there were no Russian papers on chemical processing or on waste disposal. Contributions from other nations were sufficiently numerous and sufficiently important to give the Conference a truly international flavour.

One of the most valuable papers in the *B* Sessions, and perhaps one of the most important in the whole Conference, was that given by Mr. Jesse Johnson, head of the Raw Materials Division of the U.S. Atomic Energy Commission. He estimated that at least one million tons of uranium can be extracted at a reasonable price and that much more is obtainable. This means that there will be no shortage of uranium even for substantial natural uranium power schemes such as that recently announced by Great Britain. In the Russian exhibit there was a particularly fine display of uranium minerals, and the paper by H. Sankhoff on location of ore bodies by radiochemical analysis of ground waters was specially interesting, as no other country appears to have used this method systematically.

There were very detailed American papers on the production of heavy water, on the production of the atomic energy metals and on graphite, together with important contributions from Britain, Canada, France and the U.S.S.R. These papers, and the discussions which followed them, will allow those countries which hope to initiate an atomic energy programme of their own to make an appreciation of the feasibility of producing some of the necessary materials themselves. It was made clear in some of the economic discussions in the plenary sessions that the factors which the so-called under-developed countries would take into consideration in making their appreciations might be quite different from those ruling in the case of the technically advanced countries. Countries with local supplies of one or other of the necessary raw materials may not be deterred by purely economic considerations, therefore, from setting up their own factories or refineries.

The situation as regards the chemical processing of irradiated reactor fuel seems to be rather different. In spite of the fact that the chemical processing plant is an essential component in the industrial atomic power complex, and that the information released at the Conference was exceptionally complete, the discussion in the sessions dealing with this subject was restricted to the specialists, mainly those coming from the United States and Britain. This may have been due to the fact that the processing sessions were held on the penultimate day of the Conference, by which time delegates were visibly tiring; but it was more probably due to a general acceptance of the likelihood that such plants will have to be designed, built and perhaps operated by organizations within the technically advanced countries.

The sessions on waste disposal were most instructive, although here again the bulk of the information was provided by the United States and Britain. It was particularly interesting to hear an account of the elaborate storage system for highly active liquors which has been installed at the great Hanford works in the United States. Several speakers emphasized that the scale and cost of the highly active storage and disposal facilities are very greatly dependent on the nature of the reactor and chemical plant with which these facilities are associated. On the other hand, it was admitted that even some of the more elaborate systems would add only a small percentage to the cost of power generated. The real problem is the danger and embarrassment which would arise if there should be any accidental spread of these highly active liquids. There seemed to be general agreement on the policy to be adopted in a nuclear power scheme, namely, concentration, separation of cæsium-137 and strontium-90 and storage of the less dangerous residue for ten to fifteen years with ultimate burial or discharge to sea, perhaps after extracting some of the more useful isotopes.

In contrast to the chemical processing and waste disposal sessions, there were notable Russian contributions in those sessions dealing with laboratory facilities for handling highly radioactive materials and with the effects of radiation on materials. While nothing was disclosed which was outstandingly new, it was evident that the Russian laboratories are well equipped in this respect and that much useful work is going on there. Similarly, in the fields of inorganic chemistry and radiochemistry and in analytical chemistry, it was quite evident that Russian scientists are well advanced. They reported, for example, interesting work on elements such as ruthenium, americium and technetium, and a new application of the isotope dilution technique to the emission spectroscopic method of isotopic analysis. Very fine review papers were presented in most of these sessions by American authors and there were also certain outstanding contributions from the United Kingdom, notably the paper on the chemistry of ruthenium, which was far in advance of any other work on this element reported at the Conference. The Barker square-wave polarograph, which was shown in the United Kingdom exhibit at the Palais des Nations, also attracted considerable attention from analytical chemists as a new and original instrument of great potentiality.

The two exhibitions, one in the Palais des Nations and the other in the Salle des Expositions in Geneva, were both extremely good. The United Kingdom sections in particular received universal praise, which the hard-working organizers thoroughly deserved.

For chemists and metallurgists as well as for engineers and physicists, the Conference was a tremendous success. To discuss matters which have been kept secret for so long, in the free atmosphere of an international conference, was an exhilarating experience, and to establish personal connexions with other scientists who have been working in the same field was extraordinarily beneficial. Possibly after more sober appraisal, it may be found that the value of the Conference to the United States, Canada and Great Britain lies mainly in such intangible benefits as those just mentioned; but there can be no doubt that for the world at large the gain was a great one.

---

# GOUGH ISLAND SCIENTIFIC SURVEY

By J. B. HEANEY

Organizer

AN eight-man expedition, most of whose members are graduates of Oxford or Cambridge, left the United Kingdom at the end of August to carry out a six-month scientific exploration of Gough Island. The island is one of the few high peaks of the Mid-Atlantic Ridge that pierce the ocean surface, and lies some 260 miles south-south-east of the three islands of the Tristan da Cunha group; it is a remote outpost of the Commonwealth, 1,500 miles from the Cape of Good Hope, and in the path of the 'Roaring Forties', which, by all accounts, give it an unfriendly climate with frequent ferocious storms and often cold, damp and foggy weather.

The conception and organization of the Gough Island Scientific Survey were mine, but, due to medical advice, I cannot take part in the field-work, and the leadership of the party has been handed over to Mr. Robert Chambers. The expedition is actively supported by the Royal Geographical Society, the Scott Polar Research Institute, the Mount Everest Foundation, and many other bodies and scientific institutions in Great Britain.

Uninhabited by man, Gough Island is a precipitous mass of volcanic rock rising to nearly 3,000 ft.; it measures about eight miles by four, and from its western storm-beaten beaches cliffs tower to 1,000 ft. Mountaineering techniques will be employed to enable the party to travel freely over the area.

The island has been described as a 'naturalist's paradise'; and is the only remaining sub-antarctic island which has not been thoroughly investigated. It has a luscious vegetation of small stunted trees, tree-ferns, tussock grass and mosses, and a rich bird life. It is the home of a unique species of flightless rail which has lost the use of its wings through processes of natural selection; some of the insects will probably show the same degeneration. Large numbers of albatrosses and rockhopper penguins nest on Gough Island, and every year an increasing number of fur seals and elephant seals haul out to breed on the beaches. These animals were exterminated from the island by the depredations of the sealers during the past century, and since their exploitation became unprofitable the island has been visited on very few occasions. In 1904 the expedition ship *Scotia* called, homeward bound from the Antarctic, and small collections were made on the island on one day, and again in 1922 members of Shackleton's last expedition from the *Quest* spent four days ashore. Present knowledge of the island's geology and natural history is chiefly based on collections made on these two occasions, and also on those made by a Norwegian who spent a few hours ashore in 1934. That a detailed scientific investigation of Gough Island is eminently worth while is indicated in an article by Prof. R. N. Rudmose Brown, of the *Scotia's* party, when he wrote, "No doubt looked at from an impartial standpoint, Gough Island is but a relatively insignificant rock in mid-ocean, but its very isolation makes it of great interest. It may throw light on some former continuity of land in the Southern Hemisphere, and it cannot fail to elucidate various problems of biological distribution when its fauna and flora have been thoroughly investigated. It is for these reasons that its further exploration is so much to be desired".

The members of the expedition, with the qualifications and ages, are listed below: R. J. H. Chambers (leader, surveyor), 23; J. P. Hall (cameraman), 32; M. W. Holdgate (zoologist), 24; R. W. Le Maitre (geologist), 21; P. J. Mullock (radio operator), 22; J. J. van der Merwe (meteorologist), 29; M. K. Swales (zoologist), 24; N. M. Wace (botanist), 26. Van der Merwe is a South African Government meteorologist.

Gough Island lies in the path of weather approaching South Africa, and one of the tasks of the expedition will be to transmit reports five times a day to the Weather Bureau, Pretoria. By comparing simultaneous readings from Gough and from the existing station on Tristan, it should be possible to orient fronts, and to fix more correctly the centres of passing depressions so that their time of arrival in the Union may be forecast more accurately. Dr. T. E. Schumann, director of the South African Weather Bureau, is sponsoring the programme for synoptic reports, and welcomes this opportunity of testing the value of Gough Island as a permanent meteorological station. Some research will also be carried out on the air currents and local clouds formed around the island, which behaves as a small land mass in the path of a steady prevailing wind.

The main emphasis of the field-work will be on various biological programmes. First and foremost, these will consist of making thorough collections on the island; it is to be expected that there will be several species new to science. A particular study will be made of the ecology of the flightless rail, and of the other land bird—a bunting. The populations of the fur and elephant seals will be assessed for the possible future exploitation of the two species.

The invertebrate fauna of Gough Island is almost completely unknown. The isolation of the island, the diversity of its terrain and vegetation, and its comparative freedom from human interference, will make a faunistic survey especially interesting. It is hoped to use the main plant associations as the units in this survey, although a study will be made of the fauna of particular habitats such as streams, caves, beach debris and bird nesting colonies.

The botanist will make a study of the dispersal mechanisms and agents that have brought about the distribution of some of the more interesting plants; he will also investigate systems of reproduction in a few plants. Pollen analyses of peat samples and their radiocarbon dating will give some indication of the history of plant-life on the island.

The petrological examination of the lavas of Gough may provide clues as to the nature of the Mid-Atlantic Ridge. A gneissous block of 'continental' origin has been found in the crater of Tristan, and there are rocks with similar 'continental' affinities on St. Helena and Ascension; it is hoped that the rocks of Gough will provide further hints about the nature of the Atlantic floor.

The expedition's collections will be distributed to specialists for identification after the party returns, and individual members will work on their own lines of research. Papers will be published in various scientific journals, and in addition it is hoped to collect and republish all the results in a series of papers under the name of the expedition.

# CEREBRAL ACTIVITY

A JOINT meeting of Section I (Physiology) and Section J (Psychology) of the British Association on September 2 at Bristol took the form of a symposium on cerebral activity. Without being restricted to a particular theoretical issue or to data obtained from a particular discipline, this symposium provided common ground for workers from a number of different fields of inquiry relating to the problems of cerebral mechanisms. The topic chosen by the organizers of the symposium may fairly be said to be one where interdependence of different scientific disciplines is becoming increasingly apparent, and the papers which were read on this occasion were largely focused on this point.

The symposium opened with an account by Dr. C. G. Phillips (Oxford) of the essential established facts of nerve structure and function with which any theory of cerebral activity must come to terms.

Reviewing the progress in neurophysiology since the discovery late in the nineteenth century that the nervous system is built up of independent nerve cells, Dr. Phillips described the function of nerve cells in conducting impulses inwards along the dendrites towards the cell body and outwards along the axon to other nerve cell bodies or their dendrites, or to muscles. Dr. Phillips cited the evidence for a voltage gradient across the plasma membrane of the cell body and its processes and (without committing himself to a particular theory of neurohumoral transmission) outlined the sequence of events whereby signals arriving at the specialized terminals which are applied to the dendrites and cell bodies of other nerve cells result in the secretion of chemical transmitter substances which serve either to increase or to decrease this voltage gradient. The excitatory or inhibitory effect of these terminals was discussed in relation to the critical potential difference which determines the firing of a self-propagating nervous impulse.

Dr. Phillips emphasized that, in considering the nerve cell as a unit in an information system (for example, as a relay), the complexity of this unit's function must not be overlooked. Although the firing or non-firing of a nervous impulse in accordance with a certain critical voltage difference across the plasma membrane may seem a simple and unitary function, nevertheless this is only the end result of the integration of inhibitory and excitatory effects at hundreds of dendritic contacts. The cell "may be poised near to the critical firing level or it may be 'biassed off' over a range of about twenty millivolts, by preponderating inhibitory action". On one hand, there is variability in the amount of further excitation needed if the cell is to fire at all; on the other, given adequate excitation, the frequency of firing is variable over a wide range.

Dr. Phillips then turned to the question of the organization of particular types of cerebral activity, and mentioned that repetitive activity may cause an enduring facilitation of transmission from cell to cell. In suggesting that such changes could conceivably impose fairly definite pathways on an originally diffuse system of interconnexions, he was careful to point out that particular patterns of activity occurring in a more or less restricted brain region might very well engage different populations of brain cells on different occasions, and that one cannot assume an unvarying anatomical substrate for particular types of cerebral activity. In fact, although certain reflex pathways can be traced and although there is some knowledge of the traffic of impulses in a few well-marked tracts within the central nervous system, the nervous events which subserve such functions as speech and skilled movement cannot at present be traced in detail.

Dr. W. Grey Walter (Burden Neurological Institute, Bristol) gave an account of some of his investigations into the function of the spontaneous electrical activity of the brain. He suggested that this activity has an 'administrative' function in cerebral organization and, more specifically, that this activity is concerned with the distribution in the brain of information derived from the sense organs and that this is best considered as operating on a statistical basis. He also maintained that this spontaneous activity is related to temperament and social behaviour.

After stressing the inadequacy of the tools which are available for the study of cerebral mechanisms, Dr. Grey Walter pointed out that useful information can nevertheless be gleaned provided that the information extracted by one's recording instruments bears a recognizable relation to the end result of the function under investigation. He suggested, for example, that the conventional voltage-against time record is unsatisfactory, and that frequency analysis yields more meaningful information. He illustrated this point by referring to the electrical changes which occur in the brain during word association procedures and during problem solving.

Another technique which Dr. Grey Walter believes is of particular value is the graphic representation of electrical activity from various parts of the brain. A cluster of cathode-ray tubes with revolving time-bases (intensity modulation) can assist in the analysis of the electrical activity of the brain as a whole, since it is then possible to trace functional relationships between different brain areas. Thus Dr. Grey Walter claimed that this technique shows that the alpha rhythm of the brain is not a simultaneous synchronous firing throughout the brain, but that instead the alpha rhythm picked up from different parts of the scalp is not completely in phase. Similarly, a rhythmically flashing light (when the time relations of the apparatus are adjusted to the periodicity of the stimulus) is reflected in a corresponding pattern in parts of the visual display of the apparatus. This pattern may appear in a unitary fashion in a particular part of the cortex (for example, the occipital lobes), may be broken down into components, with these components distributed to different parts of the brain, or may even be conserved (in the temporal region) for a period as long as 10 or 20 sec. after the cessation of the stimulus. The cerebral consequences of visual stimulation as measured with this technique show habituation effects with prolonged stimulation and also dishabituation when subjective monotony is relieved by the introduction of a reward.

Dr. Grey Walter carried interpretation a step further when he claimed that people with similar patterns of electrical activity of the brain tend to have temperamental affinity and are well fitted for social co-operation with each other.

Dr. D. M. Mackay (King's College, London) discussed some of the theoretical problems of cerebral organization. He pointed out that the fault with the kind of analogy which compares the brain to known mechanical or electronic devices is that it is too restricted, and he stressed the necessity for a more basic and general language. This, he urged, could first most properly be employed to describe what the brain does before attention is turned to the problem of how it does it. He suggested that, given adequate definition of what the brain does, one could proceed to consider various possible alternatives as to the mechanism involved and then refer back to the known facts of neurophysiology for guidance as to which of the postulated mechanisms occurs in the brain. The theory of information and control which has arisen from recent developments in communications and automatic control systems is framed in terms which, Dr. Mackay suggested, are of sufficient generality to meet the requirements he had referred to. This basic terminology, he maintained, could be applied to both physiological and psychological data, possessed a reasonable chance of surviving changes in engineering fashion, and lent itself particularly well to a theory concerned with units with a controllable probability of passing on signals (as described by Dr. Phillips).

Dr. Mackay raised two important issues which would necessarily have to govern any theoretical model of cerebral organization: first, such a model would need to be self-organizing; secondly, it would need to be able to take advantage of the redundancy of information which is implicit in a stable environment. It would thus be necessary to work out the general principles upon which such a system as the brain would have to function if it is to take advantage of the statistical regularities of the world with which it has to deal. Similarly, Dr. Mackay argued, the question of the time which such a system would require in order to adjust itself to these regularities is a crucial one. Thus there is no possibility of a model of restricted size which could make the necessary adjustments by simple trial, error and success in relation to each alternative with which it is confronted. A principle which would be more consistent with the observed facts of behaviour, Dr. Mackay contended, is one where the system starts with "the degrees of freedom coalesced", so that the process of self-development becomes one where the probability of any particular event occurring would be reduced rather than increased during the period of organization. Dr. Mackay's suggestion is thus nearer to Coghill's theory of differentiation through maturation than to learning in terms of conditioning or simple trial-and-error learning. Finally, Dr. Mackay suggested that such a model might find its first application and its first test in relation to the effects of brain injuries, since the types of breakdown which might occur with any particular model should be predictable.

Mr. M. F. Piercy (Bristol) discussed behavioural studies of cerebral dysfunction. He pointed out that the behaviour of a normal organism in a normal environment gives very little clue as to the changed behaviour which may result from physical interference with cerebral function. Similarly, this behaviour would not be predictable on the basis of present neuro-physiological knowledge. This situation, he suggested, provides a starting-point for studies which may eventually modify both psychological and physiological theories.

As an example of studies taking their cue from clinical neurology, he cited work on the incidence of aphasia in relation to cerebral dominance. Although, in right-handed patients, aphasia occurs almost exclusively in association with lesions of the left hemisphere, nevertheless left-handed patients may sustain an aphasia as a result of a lesion of either hemisphere. There is however, he maintained, evidence to suggest that aphasia is often less severe and more transient in left-handed people. In distinction to this evidence, Mr. Piercy referred to a study of paroxysmal dysphasia (with which he had been concerned). This showed that paroxysmal aphasia occurring in association with a short-lived unilateral cerebral disturbance was more frequent in left-handed than in right-handed patients, irrespective of the side of the focal cerebral disturbance. It may be, he argued, that if a function is more diffusely organized with respect to cerebral anatomy (for example, language in left-handers), not only is restitution of function more easily achieved when the disturbance is chronic, but also that function is more liable to disruption in the face of acute interference. Conversely, in the case of a function being organized within a more restricted cerebral area (for example, language in right-handers), Mr. Piercy suggested that the function might be more resistant to acute interference (such as paroxysmal) but less capable of recovery when breakdown occurs in association with a chronic lesion. This, he said, was a tentative theoretical position which should be amenable to experimental verification or disproof.

Mr. Piercy then directed attention to studies which produced anomalous behaviour without direct interference with cerebral function. Thus, if a person's voice is recorded and played back to him through earphones with a delay of about half a second, gross disturbances of speech are liable to occur. These disturbances are not unlike those occurring in some forms of dysphasia. Similarly, a recent study carried out in Canada has shown that if sensory stimulation is reduced to a minimum for a period of hours or days, a human subject may experience hallucinations and feelings of unreality which closely resemble those occurring under the influence of hallucinogenic drugs. Similar symptomatology from radically different experimental procedures may or may not mean that a common cerebral mechanism is disturbed; but such converging lines of evidence should, he urged, at least provide strong stimulus for further research. MALCOLM PIERCY

# PROGRESS OF CANCER RESEARCH

THE annual report of the British Empire Cancer Campaign has now expanded in its 1955 edition* to more than 500 pages; consequently, this short review can only deal with a very limited number of the researches financed and organized by the Campaign. The investigations to be described can be divided into three main groupings, namely, those concerned with carcinogenesis and other studies of that kind, clinico-pathology, and radiology.

In the editorial summary to the report there is a statement which says that "steady progress continues in our understanding of the manner in which cancer-producing substances act". Unfortunately, this happy thought verges on the over-optimistic.

Work on the fashionable cancer problem, the lung cancer – cigarette smoking relationship, continues at a number of centres. One of the main difficulties, from the experimentalist's point of view, is to find some tissue which has the same sensitivity as human lung and upon which the carcinogens present in cigarette smoke could be tested. Sir Ernest Kennaway and co-workers have found 3 : 4-benzpyrene, anthracene, pyrene and acenaphthylene in the condensate from tobacco smoke, and the same compounds have also been detected in smoke from the paper in which the cigarette tobacco is rolled. Sir Ernest has attacked the difficulty of test material by using tissue-culture technique:

"Several workers have demonstrated the carcinogenic power of tobacco condensates upon the skin of the mouse, but neither the species nor the tissue concerned in these experiments is of practical importance. Human tissue can be used thus only in tissue culture. Dr. Honor B. Fell, of the Strangeways Research Laboratory, Cambridge, has kindly allowed Dr. Ilse Lasnitzki to investigate this matter. Lung tissue obtained from an early human fœtus, and therefore sterile, was found to grow well in culture without replacement of epithelium by fibroblasts.

"Such cultures are being exposed to 3 : 4-benzpyrene, and to various fractions of tobacco condensates, in order to learn whether the nuclear changes known to be produced by carcinogens in other tissues can be induced in this instance also."

M. H. Salaman and collaborators have reported interesting developments in the study of the two stages of carcinogenesis ('initiation' and 'promotion'). They find that pre-treatment of mouse skin with urethane (initiation), followed by promotion with croton oil, yields skin tumours; however, urethane, although a highly potent carcinogen for mouse lung, does not induce cancer in mouse skin when applied alone. It has now been found that for the initiation stage in mouse skin not only urethane but TEM (triethyleneimino-3-triazine) or 1 : 2-benzanthracene or β-propiolactone are also effective. The promoter, too (croton oil), can be replaced by iodoacetic acid or by chloracetophenone.

The search for chemotherapeutic drugs for cancer is undergoing an interesting change; less emphasis is now being placed on the therapeutic results achieved, and more and more on the synthesis and preparation of the drugs and upon the mechanism of their cytotoxic action from the points of view of cytology and physical chemistry.

Dr. Percy Stocks, in a study of the influence of social factors on the incidence of breast cancer in women, states:

"The figures suggest that when marriage is delayed the risk of breast cancer is increased, whatever the number of children borne, except in the group married about 30 with long duration of married life; or, otherwise expressed, that high fertility has a protective effect provided that marriage has not been delayed too long.

"In due course larger numbers will be available to establish this but taking account also of the remarkably low breast cancer rates in Japan where fertility has been high and breast feeding usually very prolonged, sufficient justification has been found for an attempt to seek answers to the following questions:

"(1) Does the mortality excess associated with zero and low fertility indicate simply a greater frequency of breast cancer, or is there also a greater probability of high malignancy when cancer occurs (i.e. higher fatality without higher inception rates)?

"(2) Is short duration of breast feeding more important than few confinements in producing the excess?"

There are no surprises in the field of morbid anatomy this year. It is good to learn that Bloom's series of cancers of the breast approaches the thousand mark, and that its full statistical analysis is being undertaken. The extraordinary statistical difficulties which bristle about every attempt to assess the effects of different forms of treatment of this disease, and the effect of varying histology, can only be solved by study of really large and uniformly recorded series such as we can hope for in this case. D. H. Patey and A. C. Thackray provide a much-needed study of the whole gland resected in cases of parotid tumour: in none of their cases (save their only adenolymphoma) was there any evidence whatever of multicentric origin—a most important point to be settled in regard to treatment. It is, however, disappointing to find they have used only ten cases.

The review of the tumours of childhood from the Hospital for Sick Children at Great Ormond Street,

---

* British Empire Cancer Campaign. Thirty-second Annual Report covering the year 1954. Pp. xxx+531. (London: British Empire Cancer Campaign, 1955.)

London, continues. There is a valuable collection of sixteen cases, seen over a period of thirty years, of Letterer–Siwe's disease, Hand–Schuller–Christian disease, and eosinophilic granuloma of bone, which demonstrates well the point that all three conditions are examples of a single entity. They range from solitary cured granuloma in older children to rapidly fatal, widely disseminated disease in the infant; but the transitions are too striking to be ignored. The prognosis in these cases seems to be better than is generally supposed. Four cases with solitary lesions were cured by local measures: of six with multiple lesions confined to bone, three are cured and none has died. Even in the disseminated disease there have been two complete cures.

There is also a review from the same source of neuroblastoma, the commonest tumour (except leukæmia) seen at this hospital. They are of especial interest as a base-line for the study of the effects of vitamin $B_{12}$ on the tumour, first mentioned in last year's report. Of ninety-four cases collected, seventy-seven are known to have died, and there have been only two spontaneous regressions. Only twenty cases were regarded as suitable for treatment by surgery or radiotherapy, and of these seven survived more than two years. Nineteen cases in all have now been treated with vitamin $B_{12}$. All were unsuitable for radical conventional treatment, though some have had incomplete surgical or radiation therapy in addition to the $B_{12}$. Substantial response seems to have been obtained in about half the cases. There has so far been only one really unexceptionable cure, lasting 4½ years. Two other survivors beyond two years have recurrences; but several other cases whose follow-up period does not yet justify their being called cures have shown most gratifying immediate responses. It must still be a matter of very great doubt whether we have in $B_{12}$ a means of cure of neuroblastoma; but it seems probable that we have a means of relief at least as effective as, say, the nitrogen mustards in chronic leukæmia. In any event, the observation throws open a new window in tumour chemotherapy.

Prof. H. N. Green, who is now director of experimental cancer research in the University of Leeds, has combined his interests in carcinogenesis and shock metabolism into a theory of carcinogenesis which has at least the merit of directing attention to some unfamiliar facts. Briefly, his main chain of reasoning is this. Many, perhaps all, chemical carcinogens have an inhibitory effect on the take of transplanted tumours. Some fractions of tar which are not carcinogenic share this inhibitory action with the carcinogens. (Tetraphene is the active agent in some of these extracts.) Use of these non-carcinogens has made it possible to show that the inhibitory action on transplanted tumours is a relatively specific one, not due to any general depression of the host's health; it has also been shown that there is inhibition of the primary induction of tumours by the carcinogens. The inhibitory action is antagonized by agents, such as cortisone, which depress the immunity to transplanted homologous tissues. These, and other arguments, lead to two hypotheses, of which the first may be readily accepted as possibly true—that the tumour-inhibitory action of carcinogens and non-carcinogens alike is due to a stimulation of the homotransplant immunity reaction. Given this, Prof. Green assumes that the action of these agents must be on the antigenic structure of the cell, and proposes in his second and major hypothesis the view that the essential action of a carcinogen on a cell consists in the alteration of its antigenic structure so that it loses its individuality and becomes antigenically neutral. That loss of antigenic specificity is an important characteristic of some tumour cells—of all transplantable tumours, in fact—is a proposition that few would deny; that it is a fundamental characteristic of all tumours is harder to accept. But the hypothesis is at least fruitful of experiments.

There is a tantalizingly brief reference to work in the cytogenetics department at Manchester on the sex chromosomes in transplanted tumours in *Microtus*, suggesting that the host contributes chromosomes to the tumour cell, of which one hopes to hear more in the future.

The range of the physicist in the realms of cancer research and treatment grows wider and more diverse year by year. Basic physical studies continue, and from them are developed new methods of instrumentation and measurement. The use of radioactive isotopes is now an everyday matter in a very large number of departments; but work is still going on, and is needed, on increasing the sensitivity and scope of present-day methods of measurement. The construction of automatic devices for the measurement and localization of radioactive material within the human body and on chromatograms is reported from several centres, and the co-operation of the physicist is being sought more and more by his colleagues in their biochemical and biophysical investigations, as well as in the more accustomed radiotherapeutic uses of radiation.

The commercial development of equipment capable of producing beams of radiation of 1 MeV. and greater has necessitated increased study of the radiation effects occurring at these levels, and also the production of methods of measurement more suitable for these energies. A calorimetric method of dosimetry seems to offer a very good alternative to the more standard ionization methods for beams of X-rays of quanta 3 MeV. and greater. The use of a 1,000-curie source of cobalt-60 has also led to the study of the dose distribution obtained in the beam, and consideration of the best use of the beam for radiotherapy.

With the increasing use of radioactive materials, and wider range of radiations now in current use, the study of health physics achieves greater prominence each year. In this report, as well as the more usually considered radiation hazards, studies are reported on the possibility of the protection of bronchitics and asthmatics against 'smog', both indoors and out.

At the same centre the radon content of the atmosphere under conditions of fog or excessive smoke is being measured with the aid of specially built apparatus which permits the measurement of small amounts of radioactive gases.

The effect of whole-body radiation is being studied at a number of centres with particular reference to protective materials and to the result of partial shielding. The use of iron-59 as an indicator of the effect of various dosage-levels on the erythropoietic system, and also of the effect of changes in dosage-rate and of the comparative effect of X- and neutron-irradiation, continues. This should be of considerable value in assessing the total amount of whole radiation received either by design, after radiotherapy, or by chance after an occupational accident or thermonuclear explosion.

# JAMES PARKINSON (1755–1824)

By JOAN M. EYLES

THE incidence of Parkinson's disease, or paralysis agitans, is sufficiently high for most people to know something of its nature, or at least to have heard of it. Yet the story of the life and activities of the man who gave this crippling disease his name is not widely known, and it may surprise many to learn that in his day he attained distinction, not only as a physician, but also as a geologist and as a social reformer.

On September 17, an inscribed marble tablet was unveiled in St. Leonard's Church, Shoreditch, to commemorate the memory of "James Parkinson, of Hoxton, Surgeon and Apotheoary". A short service preceded the ceremony, and the Rev. Meredith Davies, in an address to the congregation, described Parkinson's close association with the parish and his wide humanitarian interests. He also mentioned the "untiring efforts and tenacity" of Dr. A. D. Morris, formerly medical superintendent of St. Leonard's Hospital, who for a number of years had not only interested himself in Parkinson, but also had been instrumental in inspiring local interest in this remarkable man.

The tablet, the funds for which had been provided by the generous efforts of the nursing staff of St. Leonard's Hospital, was then unveiled by Dr. Morris, who pointed out that it commemorated Parkinson's geological as well as his medical achievements. Among those present in the church were two direct descendants of Parkinson, Dr. Robert Tringham and Mr. Herman Saunders, while local interest was marked by the presence of the Mayor of Shoreditch. Members of the medical profession who attended the ceremony included Sir Zachary Cope, president of the History of Medicine Section of the Royal Society of Medicine, Mr. Macdonald Critchley, Sir Allen Daley, Dr. Donald Hunter, Mr. T. B. Layton and Mr. A. Dickson Wright. After the service Miss Bell, matron of St. Leonard's Hospital, and her staff entertained the visitors to tea at the hospital, where interested glances were directed to the plaque recording the fact that Nurse Edith Cavell had once been assistant matron there.

Earlier in the week Parkinson's name had been to the fore at the meeting of the Second International Congress of Neuropathologists, held at the Royal College of Surgeons of England during September 12–17. The president of the congress, Dr. J. G. Greenfield, referred to him in his opening address on "Historical Landmarks in the Pathology of Involuntary Movement", and several papers read during the week were concerned with Parkinsonism and Parkinson's disease. Very appropriately, as 1955 is the bi-centenary of Parkinson's birth, an exhibition was arranged at the College by the librarian and Dr. Morris to illustrate the many facets of Parkinson's life. A portrait, however, could not be discovered, and one is still being sought.

James Parkinson was born in Hoxton on April 11, 1755, and spent all his life in the parish. The son of a surgeon, he himself qualified in 1784, and in 1785 attended the surgical lectures of John Hunter, and took full notes in shorthand. Many years later these were transcribed and published by Parkinson's son, James Keys Parkinson, who was also a surgeon.

Little is known of Parkinson's early life, except that as a pacifist and political reformer he was the author of many pamphlets written either anonymously under the pseudonym of "Old Hubert", including "Revolutions without Bloodshed; or Reformation Preferable to Revolt", which appeared in 1794. He was a member of various secret societies, including the London Corresponding Society, and when some members of the latter were arrested and charged with complicity in what became known as the "Pop-Gun Plot", Parkinson gave evidence before the Privy Council in their favour and published pamphlets maintaining their innocence.

Parkinson then seems to have directed his activities into rather more innocuous channels, issuing in 1799 "Medical Admonitions for Families", which went into five editions in the next ten years, followed by the "Villager's Friend and Physician" and "Dangerous Sports" in 1800. In the latter year he also published another best-seller, his "Chemical Pocket-Book", which was "calculated, as well for the occasional reference of the Professional Student, as to supply others with a general knowledge of Chemistry". It had a good reception, and was reprinted in the United States, with notes by James Woodhouse, professor of chemistry in the University of Pennsylvania. In this book, as in other of his works, Parkinson showed he had read widely, much of the "Pocket-Book" being a digest of recently published work in chemistry.

His first geological work, a large quarto with many illustrations, appeared in 1804, with the impressive title "Organic Remains of a Former World: Volume I, The Vegetable Kingdom". This volume includes a useful historical review of early books about fossils. Two more volumes appeared in 1808 and 1811 respectively, and were concerned with vertebrate and invertebrate fossils. In the histories of geology, Parkinson's work has received less notice than it deserves, although it has recently been stated that "its appearance was the outstanding event in the history of our scientific knowledge of British fossils"[1]. There is little doubt that Parkinson, who was an original member of the Geological Society of London, was highly esteemed by his contemporaries for his scientific knowledge of fossils at a time when most people were content merely to collect them. In several papers published in the *Transactions of the Geological Society of London*, he assisted in naming the fossils. Parkinson himself had a paper in the first volume of the *Transactions*, entitled "Observations on some Strata in the Neighbourhood of London, and the Fossil Remains contained in them", which is noteworthy as the first detailed account of the strata of the London basin. In this paper he refers to the discovery of William Smith, that strata could be identified by their contained fossils. Elsewhere Parkinson mentions his friendship with the Rev. Joseph Townsend, who was the first to appreciate the value of Smith's discovery.

Parkinson wrote many articles for medical journals which indicate he was a careful observer; and he published several tracts which show his zeal as a social reformer. It was in 1817 that he published the "Essay on the Shaking Palsy" which has brought him eponymous immortality. In 1822 he received recognition from the Royal College of Surgeons of England with the award of its Honorary Gold Medal. This is of greater interest when one learns that he was the first to receive the award, which had been instituted in 1802, and that it has only been bestowed fifteen times in the past hundred and twenty years. It is stated in the minutes (a copy of which was included in the College exhibition) that the award was made "in consideration of his useful labours for the Promotion of Natural Knowledge particularly expressed by his splendid Work on Organic Remains".

Parkinson died in 1824 and was buried in the graveyard of St. Leonard's Church, though the exact location of his grave is unknown. His fine collection of fossils was sold at public auction in 1827, some being acquired by Sedgwick for the museum in Cambridge, others passing to Oxford, Haslemere, and into private hands. Some now rest in the British Museum (Natural History). His name is preserved in geological as well as medical circles, for the ammonite *Parkinsonia parkinsoni* and the crinoid *Apiocrinus parkinsoni* are both well-known fossils from the Inferior Oolite. It is satisfactory to learn that medical historians are now busy rescuing Parkinson from undeserved obscurity[2].

# OBITUARIES

## Prof. F. Blakemore

The sudden death on August 7 of Prof. Frederick Blakemore at the early age of forty-nine comes as a great shock to his friends and colleagues both within and without university circles. He qualified at the Veterinary School, University of Liverpool, in 1927, and then spent three years in general practice. In 1931 he moved to Cambridge as veterinary investigation officer for the eastern counties, where he remained until 1948. This was a period of intense activity demanding the closest collaboration with veterinary surgeons, agriculturalists and research workers, in a variety of fields. He would leave early in the morning to visit veterinary surgeons and farmers in the wide district which he covered, and his reputation as a sound adviser on all problems of animal health and disease was unrivalled. On his return he would plunge himself into his laboratory investigations, for which his enthusiasm was unbounded. The volume and high quality of his work during this period were an example to the younger men with whom he was associated. He had an uncanny knack of selecting the problems in the field which were worthy of intensive laboratory study. The impact of his scientific mind on a problem was shown by his unusually clear exposition of a subject. The extensive researches which he completed at Cambridge could not have been undertaken without the help of collaborators, many younger than himself, who owe much to his kind guidance and stimulating encouragement. His distinction in the research field was recognized by the award of the Dalrymple-Champneys Cup by the British Veterinary Association.

The high qualities which emerged during this period marked Blakemore as a man of sound judgment, and it was no surprise to his friends that he was appointed superintending investigation officer for England and Wales. This branch of the Ministry of Agriculture had reached a critical stage in its development. The absorption of the county veterinary officers had been completed, but the service had not been moulded into a closely knit unit. To this task Blakemore brought his gifts of dogged persistence, persuasion and foresight, so that with the help of his colleagues he was able to build up an independent service complementary to the field officers of the Animal Health Division.

In 1948 he was appointed to the newly established chair of veterinary studies in the University of Bristol. He found in university circles, particularly in the person of the Vice-Chancellor, a keen interest in veterinary science and a desire to fashion a school on lines differing possibly from those of the older veterinary schools. Blakemore tackled with enthusiasm and sound common sense the problem of utilizing the resources of existing University departments, but at the same time developing an independent veterinary school with ramifications in Bristol and at the field station at Langford. The buildings which have been erected are a tribute to his sound planning; but, of themselves, they would never have created a flourishing school. The measure of his success was his ability to attract from the profession young men who were fired with his own ideals. The University of Liverpool recognized his outstanding merits by awarding him an honorary degree of doctor of veterinary science.

The high standing of the Bristol School is a collective victory; but it owes much to the knowledge which Blakemore brought of the practical side of his profession, as well as to his ability to take firm decisions and his clear-sighted judgment of men. Undoubtedly by his untiring efforts he spent himself to the limit. He will be sadly missed by his professional colleagues. The deepest sympathy is extended to his widow, who loyally supported him, and to his family.

R. E. Glover

## Mr. E. T. Leeds

Edward Thurlow Leeds, who died at his home, 88 Woodstock Road, Oxford, on August 17 at the age of seventy-eight, was successively assistant keeper and keeper of the Ashmolean Museum, Oxford, and was an archæologist of outstanding ability.

As assistant keeper of the Department of Antiquities in the Ashmolean during 1908–27, Leeds was responsible for much of the day-to-day work in the Department. His systematic mind and studious attention to detail, as well as his strong sense of custody, made him remarkably well fitted for such a post in a great and growing museum, and his flair for rapidly assimilating new knowledge soon gave him a mastery over all the material under his charge. From 1928 until 1945, when he retired, Leeds was keeper both of his Department and of the Ashmolean. Though he never neglected his Department and never failed to keep a firm daily grip on its working, administrative duties, which fell to him as keeper of the Museum, came to occupy more and more of his time, involving, as they did, the planning of no less than four major additions to the fabric (the Weldon wing, the Griffith Institute, the Drapers' wing and the Beaumont Street wing) as well as several internal reconstructions of fabric or fittings. His flair for attention to detail ensured that all this work took place with but the minimum interference with day-to-day duties and with practically no interruption of the Museum's service to the public.

That Leeds, as a busy and successful museum official, did not neglect the claims of scholarship is shown by the many excavations on local sites which he undertook (notably those of the Neolithic causeway and settlement at Abingdon, Berks, the Iron Age camps at Chastleton, Oxon, and Chun Castle, Cornwall, and of the Anglo-Saxon village at Sutton Courtenay, Berks) and by the list of six books and more than ninety smaller papers which appear in the bibliography of his writings in the forthcoming volume of essays entitled "Dark-Age Britain" offered to him by a group of his friends and pupils. His chief work lay in Anglo-Saxon studies. His book, "The Archæology of the Anglo-Saxon Settlements", published in 1913, can fitly claim to have been epoch-making, as it laid the foundation of all the more recent work on the subject, and showed, once for all, how great a contribution archæology could make to a study which had previously seemed to be almost solely the prerogative of the historian. He followed this with two more books and numerous papers, which showed how, though his views may have been modified in detail as the years passed, his main arguments stood firm in his own mind and have, indeed, now won general acceptance. Besides his work for Anglo-Saxon studies, Leeds also made major contributions to scholarship in several other fields, notably with his book "Celtic Ornament" (1933), and with his work on numismatics (Roman and Chinese) and his several papers connected with Oxford inns and traders.

Leeds was Fellow, and later honorary Fellow, of Brasenose College, Oxford, and was also elected this year to an honorary fellowship of Magdalene College, Cambridge, where he had been an undergraduate. He was a Fellow of the Society of Antiquaries and a vice-president during 1929–32, and an honorary associate of the Royal Institute of British Architects.

D. B. Harden

## Prof. Haakon Shetelig

Haakon Shetelig, formerly director of the Bergen Museum and professor of archæology there, who died on July 23 at the age of seventy-eight, was a distinguished authority on Scandinavian prehistory and on the archæology of the Vikings. He was particularly well known in Britain, both for the admirable account in his "Scandinavian Archæology" (Oxford, 1937), written in conjunction with the philologist Hjalmar Falk, and for his interest in the archæological traces of the Vikings in the British Isles, of which he left a permanent memorial in the six parts of "Viking Antiquities in Great Britain and Ireland", published in 1940 (pts. I–IV) and 1954 (pt. VI) on behalf of the Norwegian Scientific Research Fund of 1919. Much of the writing was contributed by British and Norwegian scholars, but Shetelig edited the whole work and himself contributed a masterly introduction to the history of the Vikings in Western Europe.

Shetelig was a genial and hospitable as well as a learned man, and he had an abiding love and respect for Britain. He had a particularly warm place in his heart for the amateur scholar, whom he regarded as the fine flower of our society in the days of its prime. It must have given him peculiar pleasure to be awarded the Gold Medal of the Society of Antiquaries of London, a recognition which came to him in 1939.

Grahame Clark

## Dr. C. H. N. Jackson, O.B.E.

Dr. C. H. N. Jackson, chief entomologist of the East African Tsetse Research Organization, died in hospital in England on July 28. His whole career was devoted to research in East Africa, his first appointment being in 1927 as zoologist to the Department of Game Preservation in Tanganyika. C. F. M. Swynnerton was the head of the Department, and Jackson was one of the team of able young men who Swynnerton inspired to work on the tsetse fly which then, as now, was one of the major problems of East Africa. Swynnerton persuaded his Government and the Colonial Office to set up a separate Department of Tsetse Research, and Jackson was appointed as survey entomologist to it in 1932. He became senior entomologist in 1936. In 1948 tsetse research became the responsibility of the East African High Commission, and Jackson was appointed research officer in the Tsetse Research Organization, becoming chief entomologist in 1951. He held the degree of D.Sc. of the University of London, and was appointed O.B.E. in the Queen's Birthday Honours List this year.

Jackson was, like Swynnerton, an excellent field-worker, and spent much of his time almost completely isolated from the amenities of civilization and even from his colleagues. His work, carried out over so many years at Kakoma in Central Tanganyika under difficult and uncomfortable conditions, provides data on the tsetse of continuing value to all concerned with similar problems. But Jackson was not only a field-worker; he combined this with rigorous academic standards, and an ability to keep up to date with theoretical and laboratory work in his own and allied subjects. He will be particularly remembered for his work on natural populations. This applied primarily to the tsetse fly, but is accepted by others as applying much more generally to other ecological problems. A particular contribution was his development of the 'marking' technique, by which tsetse flies were marked with spots of paint in such a way that the date and place of release could be indicated and recaptures could also be recorded. He spent much of his leave analysing his data, and was among the first field-workers to apply the methods of Sir Ronald Fisher to his results. He had a real enthusiasm for his subject which he communicated to those who discussed his work with him either in the laboratory in Britain or in the field in East Africa. His work, though individual, was also part of the work of a team of scientists who have done much to make tsetse control over large areas a possibility.

Kenneth Mellanby

## Mr. R. L. Collett, M.B.E.

Ronald Leslie Collett, who died on August 15, will be remembered for the devoted service he gave to the profession of chemistry as assistant secretary (1925–44) and as registrar (1945–51) of the Institute of Chemistry of Great Britain and Ireland, now the Royal Institute of Chemistry. Throughout that period he was always available for consultation by students and members of the Institute on matters affecting their careers, and there were few who at some time or other did not benefit from his advice and help in resolving professional or personal difficulties. Even those who at first were overawed by the luxuriance of his eyebrows or his somewhat didactic manner soon came to regard him as a friend and confidant. His obvious sincerity and complete honesty of purpose won for him the esteem and affection, not only of innumerable chemists, but also of many government officials, fellow bird-watchers and members of the Savage Club—and, not least, of those whose opinions he combated most vigorously.

Born in 1886, Collett was educated at St. Paul's School, London, and, after graduating in natural sciences from Trinity College, Cambridge, he specialized in the chemistry of food, drugs and water at King's College, London. He was elected a Fellow of the Institute of Chemistry in 1913. During the First World War he was first commissioned in the Middlesex Regiment, but was later transferred for specialist duties in connexion with water supplies and served for three years in France as a captain in the R.A.M.C. After the War he was successively chemist to a brewery and a member of the scientific staff of the newly formed British Leather Manufacturers Research Association.

He took a close interest in the work of several scientific societies and had been a vice-president of the Society of Public Analysts, now the Society for Analytical Chemistry. Before his appointment as a salaried officer of the Institute of Chemistry, Collett had been a member of its council and had served as honorary secretary and honorary treasurer of its London Section. During the Second World War he gave valuable assistance to government departments in connexion with the utilization of the services of qualified chemists and was afterwards appointed M.B.E. After his retirement he was attached in an advisory capacity to the Association of University Teachers, and continued to act as a consultant on the engagement and conditions of service of chemists in industry.

H. J. T. ELLINGHAM

# NEWS and VIEWS

## Chemical Technology at the University of Edinburgh : Prof. K. G. Denbigh

THE first occupant of the recently instituted chair of chemical technology in the University of Edinburgh is to be Dr. K. G. Denbigh, who will take up his duties there in October. Dr. Denbigh is at present a University lecturer in the Department of Chemical Engineering, Cambridge. He is forty-four years of age, and was educated at Queen Elizabeth's Grammar School, Wakefield, and at the University of Leeds, where he graduated with first-class honours in chemistry in 1932. He continued his studies by research on the fluorides of sulphur and was awarded the degree of Ph.D. His old University has recently recognized his distinguished contributions to a wide field of scientific subjects by conferring upon him the degree of D.Sc. Dr. Denbigh's career has been almost equally divided between chemical industry and university teaching. He has held appointments with Imperial Chemical Industries, Ltd., and with the Ministry of Supply Royal Ordnance Factories and was for a time a lecturer in the University of Southampton. In 1948 he was appointed to a University lectureship in the then newly-established Department of Chemical Engineering at Cambridge, and from the start he has been largely responsible for the teaching of chemical thermodynamics and associated subjects. His researches have been mainly concerned with the kinetics of reactions between gases and liquids and between gases and solids, and he has published a number of papers on these topics and in the general field of chemical kinetics and thermodynamics. His monograph "The Thermodynamics of the Steady State" (Methuen, 1951) has become very well known, and a text-book, "The Principles of Chemical Equilibrium", has been announced by the Cambridge University Press for the autumn. Dr. Denbigh is a Fellow of the Royal Institute of Chemistry and a member of the Institution of Chemical Engineers, and he is a member of the Education Committee of the latter organization.

## The Animal Health Trust : Dr. K. C. Sellers

THE Animal Health Trust has appointed Dr. Kenneth Charles Sellers to be director of its new Farm Livestock Research Station at Stock, Essex. Dr. Sellers, who is thirty-nine, is at present in the service of the Ministry of Agriculture as veterinary investigation officer in Yorkshire. He was trained at the Royal Veterinary College, London, and then went to the University of Cambridge, after which he was appointed to the staff of the Institute of Animal Pathology at Cambridge. He remained at the Institute, with the exception of war service, until joining the Ministry of Agriculture. Dr. Sellers has already contributed some thirty papers on widely varying aspects of disease problems, including a survey of losses during pregnancy and parturition in sheep, vitamin deficiencies in livestock, bovine mastitis, ketosis in pregnant ewes, and various nutritional problems. Pending completion towards the end of the year of a new range of laboratories at the Farm Livestock Research Station at Stock, temporary laboratory accommodation has been provided at Lilystone Hall, where alterations have been made to meet library, lecture hall and reception room requirements and for provision of residential flats for various members of the staff. The nucleus staff from the old Farm Livestock Station at Houghton Grange in Huntingdonshire have moved to Stock.

## Perkin Centenary Celebration in 1956

IN 1856, William Henry Perkin, then aged eighteen, discovered the first synthetic dyestuff, later called 'mauve', and from this discovery have developed the modern dyestuffs industry and the greater part of the world's organic chemical industries. It is planned to celebrate in London, during May next year, the centenary of this discovery, and six bodies are co-operating in making the arrangements: the Royal Society; Chemical Society; Society of Chemical Industry; Society of Dyers and Colourists; Royal Institute of Chemistry; and the Association of British Chemical Manufacturers. Under the patronage of H.R.H. the Duke of Edinburgh, the president of the celebration is the president of the Royal Society, with the presidents of the sponsoring societies as vice-presidents. An organizing committee has been set up under the chairmanship of Sir Robert Robinson, and four sub-committees have been formed to deal with the following aspects: technical and scientific; social; finance; and publicity. It is intended to appeal for a fund of £100,000 and with this money to set up a trust fund which will finance Perkin Centenary Scholarships designed to promote, advance and encourage technical education in relation to all aspects of the fabrication or application of colouring matters. The main part of the celebration will take the form of a series of five lectures dealing with the effects of Perkin's discovery on life and industry during the past hundred years. There will also be a conversazione at which an opportunity will be given for overseas delegates to meet one another and the delegates from Britain. The general secretary for the celebration is J. W. Nicholls, c/o Society of Dyers and Colourists, 19 Piccadilly, Bradford 1, Yorks.

### Independent Television Authority: Croydon Transmitting Station

The first station of the Independent Television Authority, to be known as the Croydon Station, was officially opened by the Mayor of Croydon on September 13, and full-scale programmes started on September 22. This is also the first television station in Great Britain to operate in Band III (174–216 Mc./s.), the frequency of the vision carrier being 194·75 Mc./s. and that of the sound carrier 191·27 Mc./s. The British standard 405-line system is used, in common with the existing B.B.C. Band I service. The station is situated on high ground, 375 ft. above sea-level, at Beulah Hill, and the mean height of the aerial above ground-level is 175 ft. The aerial consists of a vertical array of eight stacks, each stack containing four half-wavelength dipoles set at the corners of a square: the two top and two bottom stacks are rotated 11° with respect to the remaining four stacks in order to achieve as nearly as possible a circular radiation pattern in the horizontal plane, and the array has a gain of six relative to a half-wavelength dipole. The radio-frequency power outputs of the vision and sound transmitters are 10 and 2·5 kW., respectively, and the corresponding effective radiated powers are thus 60 and 15 kW. It has been estimated that, with these radiated powers, the primary service area, which is included within the 2 mV./m. field-strength contour, extends roughly thirty miles to the north and west from the transmitter, and some twenty miles to the east and south, though there is a narrow belt of shadow a few miles wide, and with field strengths between 0·5 and 2 mV./m., running just to the south of the North Downs. Within this area there are about 9·5 million potential viewers. The 0·5 mV./m. field-strength contour, defining the limit of the secondary-service area, lies five to ten miles beyond the 2 mV./m. contour, the greatest ranges being in a north-easterly direction from the transmitter, and a further million potential viewers are contained within this belt. Such measurements of field strength as have been made agree well with the predicted values. It is the intention of the Authority to increase in the near future the effective radiated power of the Croydon station to 120 kW.; and it is anticipated that the second station of the Authority, near Lichfield, will be ready to radiate programmes, also in Band III, early in 1956.

### International Fisheries Convention: Meeting of the Permanent Commission

The fourth meeting of the Permanent Commission set up at the International Fisheries Convention, 1946, was held in London during September 13–16. Delegations attended from all the thirteen Member States—Belgium, Denmark, Federal Republic of Germany, France, Great Britain, Iceland, Ireland, The Netherlands, Norway, Poland, Portugal, Spain and Sweden—and observers from the International Council for the Exploration of the Sea, the United Nations Food and Agriculture Organization, and the International Commission for the North-West Atlantic Fisheries. The discussions at the meeting centred mainly upon the 'industrial fisheries', the minimum size of mesh of trawl nets, and the arrangements for enforcing the provisions of the Convention. The provision whereby any catch not destined for human consumption (that is, 'industrial fisheries') may contain up to 10 per cent of undersized fish of species which the Convention protects was extended until May 1958 in order to allow further time for the International Council for the Exploration of the Sea to report on the problem. In view of the considerable 'industrial fishery' for sand eels (*Ammodytes*) that has developed during the past two years in Denmark, the Commission agreed to include sand eels in the species which are exempted from provisions relating to the minimum size of mesh. As a result of experiments on the relative selectivity of light and heavy trawls and the effects of the prescribed minimum mesh size for trawls in the southern part of the Convention area, two interim measures were decided upon: first, that the 75-mm. minimum mesh should remain unchanged for a further year; secondly, that trawl nets made of single twine and containing no manila or sisal might have a minimum mesh size of 5 mm. less than that applicable to other trawl nets. The International Council for the Exploration of the Sea was asked to advise on a more detailed definition of a light trawl. The Commission will hold its next meeting in London, starting on May 8, 1956.

### Paint Testing Laboratory at the Borough Polytechnic, London

On September 16, Lord McCorquodale opened the new Paint Testing Laboratory at the Borough Polytechnic, London, and presented to Mr. Hubert Secretan, the chairman of the Governors, testing equipment purchased from funds subscribed by industry, through a committee consisting of representatives of the Society of British Paint Manufacturers; the London Colour, Paint and Varnish Manufacturers' Association; and the London Sections of the Paint Manufacturers and Allied Trades Association and the Oil and Colour Chemists' Association. The testing equipment installed is similar to that used extensively in government and other laboratories for the examination of the properties of paints; for example, resistance to humidity and other atmospheric conditions. The Borough Polytechnic, which is one of the twenty-five institutions in England and Wales recognized by the Ministry of Education as senior colleges of technology, has for sixty years provided courses in paint technology. Lord McCorquodale congratulated the Polytechnic on its pioneer work and appealed to industry to make the fullest use of the facilities provided, at a time in the history of Britain when all industries—and the nation as a whole—require technologists of high calibre and sound training. Industry, he said, must not only be concerned with present and immediate needs, but should attempt also to forecast the changes likely to come about in the next decade.

## Journal of Electronics

THE first issue of the *Journal of Electronics*, a new scientific publication, appeared in July (London: Taylor and Francis, Ltd. 20*s*. each part; subscription, £5 10*s*. for 6 parts). Sir Edward Appleton welcomes the new journal in a foreword to the first issue, and the editor, Dr. J. Thomson, explains and discusses the title, to which different readers might otherwise attach very different meanings. Prof. N. F. Mott will be consultant editor on the new journal. The *Journal of Electronics* is to cover any behaviour of electrons when they are nominally free or only loosely bound. The chemistry and metallurgy of any materials the properties of which contribute to, or are affected by, the behaviour, design and properties of new electronic devices are included; but descriptions of equipments using electronic devices, already well catered for elsewhere, are excluded. Several of the papers in the first issue deal with electron dynamics; but one of the longer papers deals with the structure and magnetic properties of ferrites, and another with a mass spectrometer. The second issue will, according to its table of contents announced in the first issue, be devoted almost entirely to the intermetallic semiconductors. The new journal will appear every two months. Its progress will be watched with much interest. Comparisons with the *Philosophical Magazine* (also published by Messrs. Taylor and Francis), the size and layout of which are used, may be inevitable; but they could act as a powerful spur, particularly to the many young scientists engaged in the fields now specially catered for, to set and maintain a high standard of scientific writing and hence to justify fully the new venture.

## U.S. Geological Survey Technical Files in Palæontology

A TECHNICAL file concerning the Cambrian fossils of the world has been prepared by personnel of the Paleontology and Stratigraphy Branch of the U.S. Geological Survey from an earlier file compiled by Dr. C. E. Resser, of the U.S. National Museum. This is now available as an 'open file report' of the U.S. Geological Survey, and positive microfilm or paper facsimile copies may be purchased at cost of reproduction by filing a prepaid order with the Map Information Office, U.S. Geological Survey, Washington 25, D.C. Charges are based on current materials and labour costs. As in previous releases of technical files, no guarantee of the accuracy of the file is made. It consists primarily of uncritical compilations in large part brought together by clerical help, and commonly not checked as to accuracy or consistency of usage; on the other hand, the file is a useful research tool in judicious hands, and it is being made available to the profession at large. The nature of the material and the amount of professional time that would still be required to prepare it for publication has determined the form of release. The technical files of the Paleontology and Stratigraphy Branch that are now available are: objective synonymy catalogue of the Cambrian fossils of the world (5 microfilm rolls; more than 14,000 images); compendium of palæobotanical species (28 microfilm rolls; 135,490 images); palæobotanical bibliographical index (5 microfilm rolls; 17,356 images); Mesozoic species index—North and Central America, including the Caribbean (8 microfilm rolls; 25,459 images); Mesozoic species index—South America (3 microfilm rolls; 8,345 images); Cushman catalogue of Foraminifera (33 microfilm rolls; 118,967 images). The original records and subsequent additions to them remain available in the Survey's offices in the U.S. National Museum, and with the Museum's "Cushman Collection".

## Wild Life Preservation in Burma

U. TUN YIN, formerly of the Burma Civil Service, reports that the Wild Life Protection Act of 1936 is still in force in Burma (*Oryx*, 3, No. 2; August 1955). The only blot appears in section 6, which, *inter alia*, gives protection to the rhinoceros. Unfortunately the section contains the phrase "provided that it shall not be an offence for any physician or druggist to possess or sell, or for any person to possess for private medical purposes rhinoceros blood or any preparation thereof". This exception was essential or the Act would not have been passed; many people in Burma have implicit faith in the efficacy of rhinoceros blood for medicinal purposes. U. Tun Yin writes that the Forest Law Amendment Committee has recommended the deletion of the proviso and this should lead to greater conservation of the rhinoceros. A further difficulty arising from the Act is that its application to the States comprising the Union of Burma is complicated and obscure. It does not apply, for example, to the Kachin State. The few Sumatran rhinoceros which survive there are wholly unprotected, as are also, in that State, takin, musk-deer, panda, goral, serow and other rare animals. If these are to be saved, not only must the Act be extended to the Kachin State, but also the Kachin Hill Tribes Regulation and the Hkamti Long Administration Order must be amended. There should be a uniform wild-life protection law throughout the Union of Burma. At present the law is almost ineffective, for there is no central authority directly responsible for its enforcement.

## New Ammonites

SOME new and little-known ammonites in South Africa have recently been described by E. C. N. van Hoepen (*South African J. Sci.*, 51, No. 12; July 1955). One, an unusually large form of *Pervinquieria* (*Styphloceras*) *multicostata* from Zululand, is described as the biggest *Pervinquieria* yet discovered. From the Umsinene River come some large specimens which represent a new species that has been named *Puzosia willemventeri*; a new genus of *Scaphites*, represented by a new species, is described under the name *Zuluscaphites orycteropusi*. A new genus, *Collignoniceras*, of the family Acanthoceratidæ, is established for two species, *C. hammersleyi* and *C. peregrinator*, and for a species previously described by Venzo as *Mortoniceras vinassai*. In the family Pachydiscidæ, a new species of the genus *Lewisiceras* is introduced and compared with four similar-looking species from Madagascar. This is the first record of this genus in South Africa. A new family, Gauthiericeratidae, is established for the two genera *Peroniceras* de Gross. and *Gauthiericeras* de Gross. Two new species of *Peroniceras*, *P. platycostatum* and *P. undulato-carinatum*, and three new species of *Gauthiericeras*, *G. libertas*, *G. obesum* and *G. planulatum*, are described. A family, Erioliceratidae, has been created for three new genera of keeled *Albian ammonites*, which lose their keel at a late stage; they have parallel flanks and their ribs are more or less overhanging backwards on the shoulder.

## The Starfish

THE eighth number of *The Starfish*, the journal of the Association of School Natural History Societies, is, like its predecessors, a tribute to the vitality and enthusiasm of natural history students and their teachers in British grammar schools. Mr. A. R. P. Hayden contributes the main article, which describes the work of the Nature Conservancy; David Spires, of Bishop's Stortford College, writes on observations he has made on the ecology of the house-sparrow during 1953–54; and R. J. Cryer, of St. Paul's School, gives an account of his investigation into a shaker mutant in mice. The usual reports from member schools are included, as are the yearly observations on mammals, birds, butterflies and moths, and plants. The report on the annual essay competition describes the number of entries as being particularly disappointing. A charge of 2*s.* for the journal is made to non-members of the Association. Each year the Society holds an exhibition which, in 1955, will be held in London at the British Museum (Natural History) on October 15; it is open to the public.

## Fat Accumulation by Algae

ON the basis of extensive analyses, D. M. Collyer and G. E. Fogg have come to the conclusion that the generally held view that fat accumulation is characteristic of certain classes of algae stands in need of revision (*J. Exp. Bot.*, 6, 17, 256; 1955). In the investigations now reported, the fatty acid, unsaponifiable lipoid, total cell nitrogen and polysaccharide contents of representative algae from different classes have been ascertained at different stages during their growth in pure culture. Species belonging to the same class have been found to resemble each other in the relative amounts of crude protein, fats and hydrolysable polysaccharide which they contain. Marked differences in composition between species belonging to different classes have been found; but it is concluded that there are no fundamental differences in the physiological relations of fat accumulation in the algae belonging to the Chlorophyceae, Eugleninеae, Xanthophyceae and Bacillariophyceae. Representatives of the Rhodophyceae and Myxophyceae, although they may in certain circumstances have moderately high fat contents, appear to differ in that in them fat accumulation is not associated with low cell nitrogen contents as it is in the other algae examined. No well-defined correlations between the unsaponifiable lipoid and either the fatty acid or total cell nitrogen contents of the algae have been found. *Euglena gracilis* var. *bacillaris* has been found to have a rather higher content of unsaponifiable lipoid than the other algae.

## Zoological Nomenclature

As from January 7, 1956, the International Commission on Zoological Nomenclature will start to vote on the following cases involving the possible use of its plenary powers for the purposes specified against each entry. Full particulars of these cases have already been published (*Bull. Zool. Nom.*, 11, Parts 7 and 8; 1955). (1) *Gnathophyllum* Latreille, 1814 (Cl. Crustacea, Order Decapoda), validation of emendation from *Gnatophyllum*; Hippolytidae Bate, 1888, and Eugonatonotidae Chace, 1937, validation of; (2) Mayaitidae Spath (L.F.), 1928 (Cl. Cephalopoda, Order Ammonoidea), validation of; (3) *Lernaeocera* Blainville, 1822 (Cl. Crustacea, Order Copepoda), validation of emendation from *Lerneocera*, and designation of a type species for; (4) proposed grant to the International Commission of authority to prescribe for generic names a gender different from that grammatically appropriate where such action is needed in the interests of nomenclatorial stability; (5) determination of a gender for (*a*) generic names in the Class Aves having the termination -rhynchus; (*b*) generic names in the Order Decapoda (Cl. Crustacea) having the terminations -opsis and -gnathus; (*c*) for the following names—*Gigantorhynchus* Hamann, 1892 (Cl. Acanthocephala); *Desmognathus* Baird, 1850 (Cl. Amphibia); *Nephrops* Leach, [1814] (Cl. Crustacea, Order Decapoda); *Syngnathus* Linnaeus, 1758 (Cl. Pisces); (6) *Varuna* Milne Edwards, 1830 (Cl. Crustacea, Order Decapoda), validation of currently accepted gender for. Proposals are also made for the adoption of the following Declarations: (*a*) Article 21: clarification of the authorship to be attributed in certain circumstances to zoological names and to actions affecting the status of such names; (*b*) Article 25: clarification of the status of names published only in the indexes of books. Comments should be sent as soon as possible to the secretary to the Commission, Mr. Francis Hemming, 28 Park Village East, Regent's Park, London, N.W.1.

## Announcements

THE fourth Coal Science Lecture of the British Coal Utilization Research Association is to be delivered by Sir Cyril Hinshelwood on October 19 at 5.30 p.m. in the lecture theatre of the Institution of Civil Engineers. He will speak on "The Carbon of Coal". Tickets are available from the Secretary of the Association (B.C.U.R.A., Randalls Road, Leatherhead, Surrey).

THE Bedson Club, King's College, Newcastle upon Tyne, will be holding its hundredth lecture on October 26, when Prof. M. Calvin (University of California, Berkeley) will speak on "The Photosynthetic Carbon Cycle". Two further lectures will be given as follows: November 25, Prof. E. A. Guggenheim (University of Reading), "The Relation between Theory and Experiment in Physical Chemistry"; and January 27, Dr. F. Sanger (King's College, Cambridge), "The Chemistry of Insulin".

THE Council of the International Union of Pure and Applied Chemistry has approved the recommendation of the Union's Commission on Nomenclature in Inorganic Chemistry that element 101 be named Mendelevium, symbol Mv. The original recommendation for this move was made at the eighteenth conference of the Union at Zurich during July 20–28, and was based on the claims of A. Ghiorso, B. G. Harvey, G. R. Choppin, S. G. Thompson and G. T. Seaborg, of the University of California, as announced in a report printed for the United States Atomic Energy Commission, *UCRL*-2943 (contract No. *W*-7405-eng-48), "The New Element Mendelevium", dated April 4, 1955.

ERRATUM. In *Nature* of August 27, p. 379, in the paragraph on super-voltage machines for X-ray therapy in the Science Museum, the misleading impression is given that betatrons and synchrotrons are widely used for hospital radiotherapy in Great Britain. They are, in fact, used for research purposes; for radiotherapy the travelling-wave linear electron-accelerator is being installed in a number of hospitals.

# INTERNATIONAL UNION OF LEATHER CHEMISTS' SOCIETIES

## FOURTH CONFERENCE

NEARLY four hundred members and guests from twenty-five countries took part in the fourth biennial conference of the International Union of Leather Chemists' Societies held in Stockholm during July 31–August 4. The official opening of the conference took place at the Kungl. Tekniska Högskolan, when in the presence of representatives from the Swedish Tanners' Federation, the Swedish Chemical Society and the University of Uppsala the president of the conference, Dr. K. H. Gustavson, called upon the veteran Swedish leather chemist, Dr. Edmund Stiasny, to declare the congress open. In the presidential address that followed, Dr. Gustavson dealt with the researches of the little-known Swedish chemist of the early nineteenth century, Carl Hyltén-Cavallius, who in the space of a short life of thirty-six years published several papers on tanning processes and also on the conversion of collagen to gelatin. His pioneer work did much to pave the way for subsequent investigations into mineral tannages.

There then followed the Max Bergmann Memorial Lecture delivered by his successor, Prof. Dr. Wo. Grassmann, of the Max Planck Institut für Eiweiss- u. Leder-Forschung in Regensburg. The subject, "Our Present Knowledge of Collagen", provided occasion for a comprehensive and lucid review of the progress of collagen research from the early days of Emil Fischer, through the work of Astbury to the modern concepts of the helical configuration proposed by Pauling and Corey. He also dealt with the many precursors and congeners of collagen that are now being widely investigated.

One novel feature of this congress was the holding of two symposia devoted to "The Properties of Leather" and "The Fundamentals of the Chemistry of Tanning Processes". In this way the organizers of the conference largely avoided one of the dangers that are apt to beset all large scientific meetings, namely, that of loading the programme with a host of unrelated papers. In these two symposia a number of invited speakers presented various aspects of the subjects which were afterwards discussed.

The symposium on "The Properties of Leather" included papers by Drs. R. G. Mitton (British Leather Manufacturers' Research Association and president of the Society of Leather Trades' Chemists), J. R. Kanagy (U.S. National Bureau of Standards), E. Baumann (Bally Experimental Station, Switzerland) and Prof. P. Chambard (École de Tannerie, Lyon). Mitton, in surveying the main physical properties of leather, emphasized the importance of the inter-fibrillary air spaces and showed how their relative magnitude affected such properties as water vapour and air transmission, thermal insulation, etc. Kanagy dealt mainly with the steps being taken in the United States by the government and by industry to establish standards by which the behaviour and reputation of leather could be safeguarded. Baumann presented the problem of leather properties from the point of view of the shoe-making industry and classified the desirable properties under three headings: (i) properties such as tear- and abrasion-resistance, and plasticity, that are important in manufacturing processes and in wear; (ii) properties such as flexibility of sole and upper leather and their permeability to water vapour, which are important for comfort; and (iii) properties such as colour stability, freedom from spue, etc., which are æsthetically important. Chambard's contribution mainly concerned methods of testing leathers in current use in France, such as sand-blast abrasion and the softening of leather in contact with water. He also outlined some recent service trials. Largely as a result of this symposium, it was agreed to set up an International Commission on Physical Testing of Leather, of which Dr. Mitton was invited to become chairman.

A whole day was devoted to the symposium on "The Fundamentals of the Chemistry of Tanning Processes", with lectures by Drs. K. G. A. Pankhurst (British Leather Manufacturers' Research Association), D. Balányi (Klippan), Th. White (Forestal Central Laboratories), A. Küntzel (Darmstadt), G. Otto (Badische Anilin- u. Soda-Fabrik), H. G. Turley (Rohm and Haas) and Mr. N. L. Holmes (R. Hodgson and Sons, Ltd.). Pankhurst outlined the work of his department on monolayer studies of tanning reactions and gave evidence of the predominant role of hydrogen bonding between phenolic groups in the tannin molecule and carbonyl groups in the protein 'backbone' in vegetable tanning. The use of model substances had provided confirmatory evidence of this. Otto, in a paper on the interaction of skin with aromatic tanning agents, dyestuffs and auxiliaries, also gave attention to this aspect and outlined the various types of chemical and physical linkage that could occur, from the strongest coulombic binding to the weakest van der Waals – London attractions. A review of the theories of vegetable tannage was given by White, who showed how modern concepts of the collagen molecule have helped in the interpretation of vegetable tanning processes. Küntzel's contribution, which was concerned with synthetic tannages, showed how modern syntan manufacturers had tended to depart from the original object of simulating vegetable tannins, having realized the immense versatility that could be achieved by concentrating on ionic types. Balányi gave a very full summary of the chemistry of chrome compounds and their reaction with hide. The papers of Holmes and Turley were essentially practical, the former dealing with modern sole leather manufacture, and the latter tracing the influence of the pre-tanning processes on the final properties of the leather. Prof. D. Burton provided a concluding résumé.

In addition to the papers presented at these two symposia, fifteen other communications were read. It is impossible to summarize all these here, but mention may be made of the following, which provoked some useful discussion. In "Studies of Leather by means of a Sonic Technique", J. R. Kanagy and M. Robinson described the propagation of sound waves through various types of leather in different directions, showing that the velocity of the waves is correlated with such physical properties as tensile strength. R. G. Mitton, in "The Diffusion of Water Vapour in Leather", provided conclusive proof that the transfer process is almost exclusively by diffusion through the interfibrillary air spaces and that diffusion through the fibres themselves is negligible. In "Tanning as a Rate Process", N. L. Holmes and H. G. Wollenberg described the use of buoyancy measurements for following the uptake of tannin by skin. Equilibrium values agreed well with chemical analysis. The uptake was exponential, with half-periods varying from several days with dilute solutions to 18 hr. for strong solutions. "The Examination of the Fastness Properties of Leather Dyestuffs", by W. Weber, put forward a proposal, eventually agreed in a plenary session of the conference, that an international commission be set up to co-ordinate the activities of the various national committees interested in this subject. Other papers dealing with dyeing were: "The Colouring of Suede Leather" (C. Alabouvette and C. Rouanet) and "The Measurement of the Colour of Leather" (J. A. Sagoschen). The problem of effluent disposal, which is becoming increasingly pressing in the leather industry, was discussed in two papers: "The Problem of Sewage in the Leather Industry" (H. Scholz) and "Financing Waste Disposal Installations" (E. B. Thorstensen). The impregnation of sole leather with synthetic resins, with the view of improving wearing properties, was discussed by P. Chambard.

In addition to the scientific and technological communications, useful committee work was carried out by the two existing International Commissions dealing with Leather Analysis and Tannin Analysis.

Social events included a visit to Skansen, where a replica of an ancient tannery and of many other craftsmen's shops attracted much attention, a sea trip to part of the Stockholm Archipelago, a reception by the Stockholm City Council and the closing banquet in the famous Gyllene Salen of the City Hall.

The conference attracted a good deal of attention in Stockholm, and besides the usual news conferences, Radio-Tjanst relayed an account of the proceedings given by the retiring president, Dr. K. H. Gustavson, and his successor, Dr. H. G. Turley. At the final meeting of the conference it was decided to accept the invitation of the Italian Society of Leather Trades' Chemists to hold the 1957 Conference in Rome.

# CANADIAN COLLOQUIUM ON THEORETICAL PHYSICS

A COLLOQUIUM on theoretical physics was held at the Canadian National Research Council, Ottawa, during June 9–17, arranged by the Division of Pure Physics of the Council in honour of Prof. P. A. M. Dirac. Owing to a prolonged illness, Prof. Dirac was unable to attend the colloquium, but he was to visit the National Research Council later. The colloquium was attended by a hundred and twenty-one physicists from Canada and forty-one from the United States. At the opening session, Dr. E. W. R. Steacie, president of the National Research Council, welcomed the speakers and visitors, and Dr. G. Herzberg, director of the Division of Pure Physics, explained the general scope and purpose of the colloquium; he said that there would be twenty-one invited papers and twenty-four contributed papers covering a wide range of subjects in theoretical physics, and he hoped that sufficient time would be available for the speakers to give an account of their subjects which would be of value both to the non-specialists and to the specialists. This purpose was admirably achieved, and the colloquium was a valuable contribution both to theoretical physics in general and, more particularly, to physics in Canada.

The opening lecture was the first of three lectures by H. A. Bethe on the scattering of $\pi$-mesons. Dr. Bethe gave an account of the experimental evidence and showed how the main properties of the meson–nucleon system could be deduced. The dominance of the $p_{3,3}$ state in $\pi$-meson scattering and the energy dependence and sign of the principal phase shifts were shown to follow from the scattering data independent of any perturbation method or detailed use of theory. His second talk gave an account of Goldberger's proof based on causality that the real part of the forward-scattering amplitude changes sign at a resonance, and then described the successes of the Chew–Low theory of meson scattering, and of the Cornell calculations based on the Tamm–Dancoff equation. Dr. Bethe's third talk gave Wick's derivation of the Low equation in meson theory and noted that Low and Chew had now shown that this equation followed from causality rather than from any detailed structure of meson theory.

S. Chandrasekhar gave a series of five lectures on problems of stability and turbulence in hydrodynamics and hydromagnetics. In his lectures on stability he concentrated principally on the manner of the onset of thermal instability in a layer of fluid heated below when it is subject to rotation and/or a magnetic field. He showed that, when subject to rotation, instability can set in either as convection and a stationary pattern of motions, or as over-stability and a purely oscillatory pattern of motions, depending on the ratio $K/\nu$ of the thermometric conductivity to kinematic viscosity. The dependence on this ratio is such that, for a layer of water subject to rotation, instability should set in as ordinary convection, while for mercury it should set in as oscillations of increasing amplitude. In these instances the experiments by D. Fultz and Y. Nakagawa confirm all aspects of the theoretical predictions. Similarly, Prof. Chandrasekhar showed that an external magnetic field should inhibit the onset of convection by thermal instability in an electrically conducting fluid such as mercury; and that the extent of the inhibition should depend on the strength of the impressed magnetic field and the electrical conductivity in a determinate way. Here again the theoretical predictions have been confirmed by experiments. In his lectures on turbulence, Prof. Chandrasekhar described his recent efforts to develop a deductive theory of turbulence. He suggested that the similarity principles of Kolmogoroff (and their extensions) provide boundary conditions at infinity for the basic equations he has derived (*Proc. Roy. Soc.*, **229**, 1 (1955), equation 32). In this way he has been able to determine in a unique manner the function and the constant which are left unspecified by the dimensional arguments. In his last lecture he outlined an elementary theory of hydromagnetic turbulence and showed that two distinct modes of turbulence exist. He distinguished these as the velocity mode and the magnetic mode, respectively. In both modes, equipartition between the two forms of energy (kinetic and magnetic) prevail among the largest eddies present; however, in the velocity mode the magnetic energy (relative to the kinetic energy) tends to zero in the small-scale Fourier components, whereas in the magnetic mode the magnetic energy tends to about two and a half times the kinetic energy. He described the bearing of these results on the possible character of the interstellar magnetic field and on Fermi's ideas on the origin of the cosmic rays.

Collective motion in nuclei and nuclear moments was discussed by G. M. Volkoff in two lectures, the first of which described the main ideas of the Bohr–Mottelson model of the nucleus. In his second lecture, Dr. Volkoff referred to recent work at the Massachusetts Institute of Technology and at Columbia University on nuclear magnetic octopole moments, and indicated briefly some features of the Bohr–Mottelson model relevant to nuclear moments. He concluded with an outline of the nuclear moment aspects of the work of his own research group at the University of British Columbia on radio-frequency spectra of nuclei in crystals, which has been reported in a series of papers in the *Canadian Journal of Physics*. In particular, a new method of measuring nuclear spin was described.

W. H. Watson gave a review of the experimental work on mechanical properties of helium II carried out at the University of Toronto and discussed their interpretation on the two-fluid theory. He pointed out that a hydrodynamical explanation cannot be given for the experimental results for the viscosity measured by the rotating cylinder method and for the relation of the zero shift of the inner cylinder, and he suggested that a better understanding of the kinetic theory of classical liquids would promote our understanding of the behaviour of a quantum liquid like helium II.

A description of the many-body problem in nuclear structure was given by R. J. Eden, the account being based on recent work by Brueckner and others at Indiana University. The simplicity of certain nuclear models gives hope that corresponding simple features can be derived by considering a system of many nucleons in strong interaction. The many-body method was illustrated by applications to the problem of nuclear saturation and to the theory of low-energy neutron reactions with nuclei.

G. Breit gave three lectures on nucleon–nucleon scattering. The first of these gave a historical survey of the subject and explained the general features of the experimental evidence and its mathematical interpretation in terms of partial waves and phase shifts. It was shown that a careful analysis of experiments at low energy is insufficient to determine the nucleon–nucleon potential, and it was indicated how high-energy data can be interpreted by a boundary condition which corresponds to a repulsive core potential between nucleons. In his second lecture, Dr. Breit discussed the limitations of potential theory in nucleon–nucleon scattering, and he described difficulties which arise when one tries to interpret meson field effects in a wave equation. Dr. Breit's third lecture was primarily concerned with high-energy data; he discussed the successes and failures of various potentials in the high-energy region and indicated the importance of relating the data for pion–nucleon and nucleon–nucleon interactions.

G. Wentzel gave two lectures on hyperon–nucleon interactions and one on rotational states of deformed nuclei. His first lecture classified the experimental information on hyperons by interpreting it in terms of their masses, spins, isotopic spins, and decay schemes. He showed that the $Q$-values indicate that very strong selection rules must operate to slow down the decay of hyperons, and described Gell-Mann's interpretation of the data by isotopic spin-selection rules. In his second lecture, Dr. Wentzel showed how some information can be deduced about $\Lambda^0$ if one assumes that the observed binding in a hyperfragment comes about by coupling to nucleons via $\theta$-particles. In his lecture on deformed nuclei, he considered the discrepancy between nuclear distortion deduced from quadrupole moments and rotational energy-levels using the Bohr–Mottelson theory. He concluded that this discrepancy cannot be removed by refining calculations and that the theory, in its present form, is untenable.

V. F. Weisskopf lectured on nuclear reactions, on the shell theory of deformed nuclei and on the proton–neutron mass difference. His first lecture described the relation between the resonance fine-structure for low-energy neutron reactions with nuclei and the broad structure obtained by averaging over resonances. It was shown that the latter can be described by neutron scattering on a complex potential having a mean absorption similar to that of a neutron in a Fermi gas. In a discussion of detailed reaction cross-sections, significant departures from the statistical theory of Niels Bohr were noted, particularly in the medium-energy range. Dr. Weisskopf's second topic was an account of the work of K. Gottfried at the Massachusetts Institute of Technology, who has calculated the ground-state energies of a deformed independent particle model of nuclei. These predict a distortion giving a minimum energy for each nucleus which agrees well with observed quadrupole moments. Dr. Weisskopf's third talk described the work of Feynman and Speisman on the electromagnetic origin of the proton–neutron mass difference and showed how an analogous mass difference also exists in a classical theory.

In addition to the invited papers described above, papers were contributed covering topics ranging from the Dirac equation in Finsler space to thermal conduction in solids. These papers were read by P. Havas and C. R. Mehl, F. A. Kaempffer, R. H. Good, C. O. Hines, H. Jehle, H. Feshbach and E. Lomon, I. Kay and H. E. Moses, D. K. C. MacDonald, Y. Takahashi, R. J. Eden, D. R. Inglis, U. Ingard and D. C. Pridmore-Brown, A. B. Bhatia, S. Gasiorowicz, R. Jastrow, H. Yilmaz, F. R. Tangherlini, F. H. J. Cornish, A. E. S. Green and K. Lee, T. Y. Wu, S. Shanmugadhasan, T. F. Morris, A. Klein, and O. Theimer. After a dinner on June 16, given by the Royal Society of Canada, Dr. D. C. Rose gave a talk on the recent cosmic-ray expedition to the Arctic and Antarctic of members of the National Research Council.

The colloquium was the first of its kind in Canada, and, judging from the comments of the principal speakers and other visitors, it was both enjoyable and useful. The distinction of the visitors from the United States indicated the great interest of American scientists in Canadian physics, and it should perhaps be noted that a fault of the meeting was the small number of papers read by Canadians. It is to be hoped that the success of the colloquium will encourage the organizers to provide further opportunities for Canadian theoretical physicists, usually so widely dispersed, to gather together and talk with each other and with visitors from the United States and elsewhere.

R. J. Eden

# LOCUST RESEARCH

## DISCUSSIONS IN LONDON

IT became apparent early this year that a number of workers engaged on locust research abroad would be on leave in England during the summer, and the Anti-Locust Research Centre, taking advantage of this fact, organized a series of informal discussions on various aspects of current research. It may be taken as an indication of the magnitude of the locust problem, and of the importance now attached to it all over the world, that from such a modest beginning grew the virtually international meetings on locust research held in London during July 18–23 in the rooms of the Royal Meteorological Society. Locust workers attended from Canada, Cyprus, East Africa, France, French Sudan, Israel, Jugoslavia, Northern Rhodesia, South Africa and Syria, and they included representatives from the survey and control organizations concerned with the major locust pests of Africa and the Middle East, namely, the desert locust, the red locust, the African migratory locust, the brown locust and the Moroccan locust. Universities and other institutions in the United Kingdom where research on locusts or related problems is conducted were also well represented.

The keynote of the meetings was informality, and although the period of fifteen minutes allotted to each speaker was too short to allow of more than a brief outline of current problems and research, the good chairmanship shown at all sessions ensured that the maximum amount of factual evidence was put before the meeting in order to provoke discussion. That this was stimulating to all was shown by the fact that almost every person who attended spoke at least once.

The meetings were arranged as a series of sessions each relating to a particular aspect of locust research. The first session, on "Aggregation and Gregarious Behaviour", was marked by the presentation of evidence which allowed gregariousness to be approached on a quantitative basis instead of by the rather vague qualitative methods used hitherto. R. C. Rainey (Desert Locust Survey), Z. Waloff (Anti-Locust Research Centre) and H. J. Sayer (Desert Locust Survey) showed that in spite of random flight orientation, and also of convective turbulence in the air and the dispersal to be expected from wind, swarms of the desert locust traverse hundreds of miles as discrete entities. They have been led by these observations to postulate reactions having the effect of keeping the swarm together, and have observed various behaviour patterns in flying swarms which may have been relevant. P. T. Haskell (Imperial College, London) spoke on the possible sensory mechanisms related to gregarious behaviour, with particular reference to auditory and visual reactions. P. E. Ellis (Anti-Locust Research Centre), W. J. Stower (Desert Locust Survey) and G. B. Popov (Desert Locust Survey) spoke on aggregation in hopper bands and in ovipositing swarms of the desert locust. It was most interesting to hear from L. D. Vesey-Fitzgerald (International Red Locust Control Service) a preliminary theory relating outbreak areas to vegetation pattern in the case of the red locust.

The second session, with Prof. O. W. Richards (Imperial College, London) in the chair, consisted of papers on the "Estimation of Numbers". J. G. Skellam (Nature Conservancy) and D. L. Gunn (International Red Locust Control Service) spoke about estimations of populations of the red locust, the latter dealing with the figures obtained by the practical method of flushing the insects by means of a motor vehicle. Z. Waloff and R. C. Rainey dealt respectively with numbers in solitary populations and in swarms. J. P. Dempster (Moroccan Locust Research Team) spoke on estimation of populations of various stages of the Moroccan locust, and W. J. Stower and C. Ashall (Desert Locust Survey) on estimations of hopper bands of the desert locust. The latter gave figures showing estimates of the number of hoppers in bands based on experienced visual observation and on various other techniques, and it was interesting to find that the former gave far more accurate results; unfortunately, it is not a teachable technique. G. Popov spoke on egg-pod distribution, a problem which is complicated by the fact that often the extent of the egg-field is difficult to establish. One important point made in the discussion was that the accuracy desired depends on the purpose for which the estimate is required; for control campaigns, figures relating to orders of magnitude of populations are generally sufficient, enabling fairly quick practical methods to be used, but for research, more accurate methods must be found.

The subject of the third session, "Factors in the Fluctuations of Populations", followed naturally that of the preceding one, and M. J. Richards (Anti-Locust Research Centre) and N. Waloff (Imperial College, London) gave papers on the fecundity and fertility of various Orthoptera under laboratory and field conditions; these papers focused attention on the great gaps in our knowledge relating the effect of environment and the physiological state of the insect to its reproductive capacity. J. P. Dempster spoke on variations in a population of the Moroccan locust relative to the changing habitat. No more than a start has been made in studying natural enemies of the desert locust (D. J. Greathead, Anti-Locust Research Centre) and other factors of natural mortality in this species (J. Roffey, Desert Locust Survey).

The session on "The Distribution and Movements of Populations", with P. R. Stephenson (Desert Locust Survey) in the chair, was marked by the interesting papers relating to movements of scattered populations presented by J. T. Davey (International African Migratory Locust Control Organization) for the migratory locust and by Z. Waloff for the desert locust. The former outlined experimental work which suggests a closed-circuit migration by night related to the seasonal rains and floods in the Niger Basin; although there were criticisms of some of the inferences on physiological grounds, nevertheless the theory is most attractive in explaining the appearance of hopper bands in approximately the same parts of the region year after year and the cyclical changes in population densities that occur over parts of the area. The results presented by Z. Waloff demonstrated that movement of scattered adults of the desert locust occurs at night. R. C. Rainey and Z. Waloff spoke on the theory that swarms of the desert locust move down-wind towards zones of convergence of air flow; this conception has the virtue of explaining the observed displacements of flying swarms and the general migration cycle demonstrated by swarm mapping. Again, some aspects of the theory were challenged, and it clearly needs much more work before it can be accepted as a complete basis for the movement of swarms, but no alternative theories were offered. The papers of P. E. Ellis and W. J. Stower on movements of hopper bands of the desert locust showed that there may be some common features in the behaviour of adults and that of hoppers.

A session on "Locust Phases" began with a review by J. S. Kennedy (Cambridge) of the recent approaches to the problem with emphasis on the endocrinological and behavioural aspects of phase variation. Papers by F. O. Albrecht (Laboratoire de Biologie Animale, Paris), P. E. Ellis and P. Hunter-Jones (Anti-Locust Research Centre) illustrated the great amount of laboratory work that is being done on many aspects of the biology, morphology, physiology and behaviour of the phases. Perhaps the greatest need suggested by these papers and the subsequent discussion of them is for basic physiological knowledge to link together the results of widely separated experimental approaches to the problem. R. E. Blackith (Imperial College, London) and D. E. Davies (Anti-Locust Research Centre) spoke on the application of statistical methods, in particular the generalized-distance method, to the analysis of phase variation in locust populations.

The research that is being done on control methods was described and discussed under the heading "Control Development", with Dr. D. L. Gunn (International Red Locust Control Service) in the chair. It ranges from field investigation of the use of aircraft against swarms, hopper bands and egg-fields to laboratory work on problems such as the cumulative effect of sub-lethal doses of insecticides, the comparative toxicity of different materials and formulations, and the comparative susceptibility of species and stages of locusts. The principal speakers included R. D. MacCuaig (Anti-Locust Research Centre) and J. H. Lloyd (International Red Locust Control Service), the former dealing with laboratory research and the latter with the various methods, including spraying adult locusts from light aircraft, used for controlling the red locust in its outbreak areas near Lake Tanganyika.

Papers by Z. Waloff, R. Skaf (Syria), R. C. Rainey, G. B. Popov and W. J. Stower, on "The Desert Locust Problem", emphasized a fact suggested at many of the previous talks, that the desert locust remains the most difficult of the plague locusts from the point of view of both research and control. The lack of clearly definable outbreak areas, the very long-range migrations of which the insect is capable, the possibility of continued nomadic existence of swarms in small numbers during interplague periods, and the large number and diversity of countries affected by it, all conspire to complicate the problem, but also to make it most challenging to research workers. B. Zolotarevsky (International African Migratory Locust Control Organization) spoke on some unusual seasonal movements of swarms of the desert locust in West Africa.

The final session, on "Trends and Needs in Locust Research", was introduced by T. H. C. Taylor (Anti-Locust Research Centre) in a talk designed to illustrate the gaps in present-day knowledge revealed by the preceding sessions. In the discussion which followed, two main trends were apparent. These were, on one hand, a call for more physiological research relating to sensory physiology, internal physiological states and the relation of such states to behaviour and to phases; and on the other hand, the treatment of the problem quantitatively from the point of view of population dynamics and ecology.

This gathering was the first for which locust research workers assembled solely to exchange views and discuss current work, previous locust conferences having been largely concerned with matters of international co-operation and control arrangements. Its success was undoubtedly due to the informal atmosphere, which encouraged the airing of unconventional and tentative proposals, and thus helped to enliven the discussions. Perhaps the emergence of several tentative and controversial theories may reduce the empiricism which has perforce formed such a large part of locust research hitherto. The Anti-Locust Research Centre, under its director, Dr. B. P. Uvarov, who took the chair at most of the sessions, is to be congratulated on initiating this stimulating review of current research on locusts.

P. T. HASKELL

# COLONIAL STUDENTS IN GREAT BRITAIN

THE inquiry conducted by Political and Economic Planning (PEP) into Colonial students in Great Britain[*] had as its practical aim to discover whether any changes in approach or organization on the part of the authorities concerned might lead to a more effective use of the resources devoted to the education and training of men and women from the Colonial territories, and to make constructive suggestions where necessary. The general implications have been discussed elsewhere in *Nature*, but the inquiry, supplemented by questionnaire, interview and field work, and the detailed information about scholarship holders kept by the Colonial Office, brought to light concrete facts and figures which are not otherwise easily available. These facts, on which the main recommendations are based, are presented in one chapter of the report and in the appendixes, and in their collection PEP was guided by four main considerations: the interest which the student or his sponsors has in the use to be made of his education; the possible wish for him to acquire more than a qualification or purely professional skill; the requirements of the society from which the student comes; and the effect which the education of Colonial students in Britain may have upon relations between Britain and the Colonial territories.

The grand total of Colonial students in the United Kingdom and the Republic of Ireland on January 1, 1955, was 10,200, but this includes 2,040 student nurses who are otherwise excluded from these statistics. In 1939 there were about four hundred Colonial students at British universities with an unknown number at other institutions. Ten years later the combined total was 3,300, of whom 1,745 were university students. For the academic year 1954–55, there were 8,160 students, of whom 2,915 were university students; but although in 1953 nearly a tenth of university students in Britain were overseas students, only one-fifth of these, or about 2 per cent of the total, were from the Colonial territories. While, however, the number of university students in Britain is slightly decreasing, the number of students coming from the Colonial territories is increasing, and, since 1950, the number of post-graduate Colonial students has become significant. During the academic year 1954–55 nearly one-third of Colonial students in Britain were Nigerians, about one-tenth came from the Gold Coast, and a small group from Sierra Leone and Gambia. More than one-fifth came from the Far East—Malaya, Singapore, Hong Kong, Sarawak and North Borneo—about one-eighth from East and Central Africa, and another eighth from the West Indies, the remaining one-tenth coming from Cyprus, Malta, Gibraltar, Mauritius, Fiji, the Seychelles and the other Colonies of the British Commonwealth. Every Colony has to-day more students in Britain than it had six years ago, but since 1949 Nigeria has replaced the West Indies as the largest single group and, with the Far East territories, has outstripped all the others in the rate of growth.

---

[*] Colonial Students in Britain: a Report by PEP. Pp. ix+257. (London: Political and Economic Planning, 1955.) 21s.

By far the greatest number of Colonial students who go abroad from their homeland go to the United Kingdom, but many go to other Commonwealth countries, including India, Australia, New Zealand and Canada. The last-named has more than six hundred Colonial students in its universities, and more than four hundred Nigerians are now studying in the United States. Some have gone to the Netherlands, and the Gold Coast Cocoa Marketing Board in 1953–54 placed about forty medical students in Germany. Colonial students are mostly older than their British fellow-students, usually between twenty and thirty, about 10 per cent of those interviewed being thirty-one years of age or more; most African students are between twenty-five and thirty. About a quarter of those interviewed were married, and nearly half of them had their wives or husbands with them in Britain; these figures are regarded as typical. About one-half had reached School Certificate standard, a quarter had taken Higher Certificate, an Intermediate degree or a first M.B.; about one-twentieth had graduated, and one-tenth had some form of professional or trade qualification. The gap between the date of their last examination at home and the commencement of their studies in Britain is often considerable, sometimes several years. About one-third of the Colonial students hold scholarships, although the proportion is much smaller than in 1949. For Gold Coast students the proportion in the academic year 1954–55 was two-fifths.

Scholars outnumber private Colonial students in agriculture, forestry, veterinary science, education, teaching diploma, social sciences, public administration, railway training and Post Office training courses, and they account for about a third of those taking architecture, medicine, pharmacy, printing and science. Three-quarters of all Colonial students take one of eight courses: law (18 per cent); engineering (14 per cent); medicine (12 per cent); allied medical subjects like dentistry (3 per cent); arts subjects (6 per cent); preliminary studies to qualify for the desired course (10 per cent); education and teacher training (10 per cent); and science (5 per cent). The largest group (law) has 1,451 students, and the smallest (science) 378. Except for nursing, law is the course with the largest number of registrations, but although a much higher proportion of West Africans study law at a university than of any other group of Colonial students, there are, relative to their numbers, fewer West Africans at the Inns of Court than any other group. The percentage of Colonial students who take a further degree appears to be slightly higher than that of British students. Little is known about the part-time students (probably several hundred in number); but the inquiry suggests that, while this group occasionally throws up a first-rate scholar, such students generally experience great difficulties with their studies and sometimes lose heart and abandon them. Just over a third of Colonial students are at universities and university colleges, about one-eighth are at the Inns of Court, and the rest mainly at polytechnics, and technical and training colleges. In 1955 more than a half were in London, only about 3 per cent at Oxford and Cambridge, about 27 per cent in the English provinces, 7 per cent in Scotland, 2 per cent in Wales and 7 per cent in Northern Ireland and the Republic of Ireland. Most of the women are student nurses; but excluding nurses, women students constitute just over one-sixth of all Colonial students, and about one-third are at universities.

# COMMONWEALTH OBSERVATORY, CANBERRA

## REPORT FOR 1954

The report for 1954 of the Commonwealth Observatory, Canberra*, follows the usual course, dealing with the work of the Observatory under eleven main headings, the first of which includes time service and positional astronomy, described under five sub-sections. Time signals were sent out from the Observatory four times each day, the average correction for the transmitted signal being 21 m.sec. and the average daily change in these corrections 2·2 m.sec. Under astrophysical investigations are included magnitude sequences, variable stars, nebulæ and clusters, stellar atmospheres, stellar spectroscopy and Mars. With regard to nebulæ and clusters, it is announced that the photographic survey of both the Magellanic Clouds has been completed with an Ektar camera. Star counts in and around the Small Cloud to magnitude 14 and 16 provide new evidence on the structure and population characteristics of the Cloud. It has been established that the cepheids in the Large Cloud, as in the Small Cloud, are much bluer than the galactic cepheids. The survey of bright southern galaxies with the Reynolds reflector is about 90 per cent complete and about 110 plates were obtained on twenty-eight nights, bringing the total to 270, of which 170 have been measured for types and diameters, and a few for luminosity distribution in some large spirals.

Under the heading of telescopes and equipment, it is satisfactory to know that the major components of the 74-in. reflector have been erected, the final assembly only awaiting the completion of the dome which, with the optical parts, arrived early in the year. The erection of the Yale–Columbia 26-in. refractor has been commenced and will be completed as soon as the dome is finished. The old clock-drive will be replaced by an electronic diurnal drive, and provision has been made for a Selsyn repeater which will indicate declination settings to 2′ of arc. The Munich zenith telescope, installed in May, has since been in constant use by the Munich observers. An iris diaphragm photometer is in operation, and preliminary trials are being made on plates obtained with the Zeiss instrument.

In the account of buildings, it is mentioned that the assembly for the 74-in. and Yale–Columbia telescopes, which was commenced during the year, is now nearing completion, but unfortunately the 50-in. dome, although new, has given a lot of trouble, and substantial improvements will be made. The figuring of the aspherical secondary for the 50-in reflector was successfully achieved in the optical shop, and this will enable the telescope to be used as a Gregorian instrument for stellar spectroscopy prior to its conversion to a Schmidt type; preliminary work for this purpose has already been carried out on a 36-in. corrector plate. Under the heading of ionospheric prediction services, reference is made to the extension and completion in some sections of the atmospheric dynamo theory. An investigation of oblique incidence propagation has been commenced by recording field strengths of inter-station communication equipment. A report has been prepared on the investigation of triple splitting, which provides new information on the mechanism of 'Spread *F*' ionospheric echoes at high latitudes. Work has been carried out on *Z* echoes.

---

* Commonwealth Observatory, Canberra. Report of the Commonwealth Astronomer for the Year 1954. Pp. 8. (Canberra: Commonwealth Observatory, 1955.)

Among the reports on liaison with other observatories may be mentioned the use of the Reynolds reflector for about a quarter of the time by the Yale–Columbia observer for the completion of a survey of the brighter southern galaxies. The Munich observers, Drs. Schmiedler and Heintz, have been working since May on a programme of absolute declinations of *FK3* stars, and, in addition, Dr. Heintz has collaborated with the Observatory staff members in working with the slit spectrograph and also with the Farnham slitless spectrograph.

Two research scholars and one instrument-maker are attached to the Observatory, and one of the scholars, Dr. A. Przybylski, received the Ph.D. of the Australian National University (where the Commonwealth Astronomer has continued to act as honorary professor of astronomy), which was the first such degree to be awarded. Prof. O. Struvè, during a short visit to Australia, spent two weeks at the Observatory, holding a number of valuable discussions, chiefly on spectroscopic problems, with members of the staff. He also presided at a symposium in Canberra at which three members of the staff presented papers under the title "Structure and Composition of the Galaxy".

# STRUCTURE OF COLLAGEN

By Prof. G. N. RAMACHANDRAN and Dr GOPINATH KARTHA
**Department of Physics, University of Madras, Madras 25**

A STRUCTURE was proposed for collagen by us about a year ago[1]. Although it explains the features of the infra-red spectrum and the chemical composition of collagen, it appears to be defective in that it disagrees with the X-ray data for stretched collagen[2] and in having too large an angle between the NH and N . . . O directions in hydrogen bonds (Pauling, L., personal communication). It is found that a small modification of the earlier structure, which preserves many of its features, fits the above evidence on collagen quite well. In addition, it also explains a number of other properties of collagen, in particular, the important role of hydroxyproline in this protein and the periodicity of 640 A. along the fibre axis.

The new structure (the projection of which along the fibre axis is shown in Fig. 1) is topologically very similar to the earlier one in that it consists of triple chains of amino-acid residues, each chain being itself a helix. However, the chains now form coiled coils, instead of being arranged with their axes parallel to the fibre axis. Thus, every third α-carbon atom (corresponding to the *G*-type of carbon atom of the earlier structure) is placed on the surface of a cylinder of radius 1·0 A., the successive ones being displaced (in unstretched collagen) by 8·58 A. along the axis of the cylinder and rotated through an angle of 36° about the axis. The single coiled coil repeats itself after thirty residues, and the repeat distance along the fibre axis is 85·8 A. The two other chains occur in such a manner that the three chains are symmetrically disposed with respect to one another. Their configuration is most easily described by saying that they are displaced along the fibre axis by + 28·6 A. and − 28·6 A. with respect to the first chain. They are also related to the latter by a rotation of ± 108° about the axis of the cylinder and a translation of ± 2·86 A. parallel to the axis. For the mathematical discussion of the structure, each chain may be described as consisting of a minor helix (following the nomenclature of Crick[3]) having ten residues in three turns, with a projection of 2·91 A. per residue along its axis, wound to form a major helix of radius 2·5 A., there being thirty residues per turn of the major helix. The major

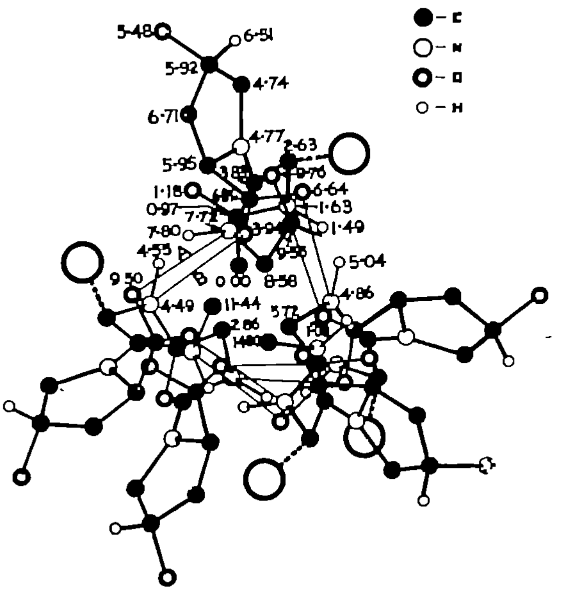

Fig. 1. Projection of the proposed structure along the fibre axis. The numbers denote the heights of the atoms above the plane of projection. Only a part of each of the three individual chains is shown. The thin lines indicate the N . . . O directions in the hydrogen bonds

helix is wound in a direction opposite to that of the minor helix, the latter being a left-handed screw if all the residues are of the *L*-type. Thus, while the thirty residues make nine turns in the co-ordinate system of the minor helix, they make ten turns in the fixed co-ordinate system of the major helix; this ensures that every third residue is similarly situated with respect to the fibre axis.

Because of the above relationships, there are only two types of inter-chain hydrogen bonds, marked *A* and *B* in Fig. 1, which are repeated by screw symmetry. In both bonds, the N . . . O distance is close to 2·9 A. and the angle between NH and N . . . O directions is about 30°. This angle would be less if the NH-bond were not coplanar with the rest of the amino-acid residue.

As in the earlier structure, two of every three NH groups are hydrogen bonded to an O of a CO group, but unlike it, the two oxygens to which they are linked are different. Thus, of every three carbonyl oxygens, only one does not take part in internal hydrogen bonding in the triple-chain cylindrical rods. This oxygen points outward from the rod and plays an important part in the cross-linking of the rods by side-chains, as shown below. As before, every third residue must be a glycine residue, and similarly a maximum of one-third of the residues may be proline or hydroxyproline.

The essential difference introduced in the structure, so far as its X-ray pattern is concerned, is that the 2·86 A. reflexion is meridional, and is the only meridional reflexion apart from its higher orders. Further, the exact repetitive unit along the fibres axis is ten residues (28·6 A.), which agrees well with the observed layer-line spacings[4]. The intensity distribution among the spots on the layer lines has been found to agree with the structure qualitatively. The distribution of intensity along the equator has been worked out in detail and is shown in Fig. 2. This is in good agreement with observations (Ramachandran, G. N., and Ambady, G. K., unpublished results), particularly with regard to the large peak at 4·7 A. and the minimum at 7·4 A. The absence of the expected spot at 7 A. is thus explained. In wet collagen, the water would be expected to occur between the cylindrical rods and, under these conditions, the minimum shifts towards smaller angles and continues to occur in the region of the unobserved reflexion of 7–8·5 A., even though the lattice expands. Further, the three-dimensional cylindrical Patterson diagram for collagen published recently by Yakel and Schatz[5] is in excellent agreement with the structure. The peak at about 1 A. in the level $z = 0$ is due to the projected component of bonds joining neighbouring atoms perpendicular to the fibre axis; that at 2·7 A. is due to the component of the almost horizontal hydrogen bond interactions; the strong one at 4·5 A. is due to the distances between the three approximately parallel amino-acid residues at the same level.

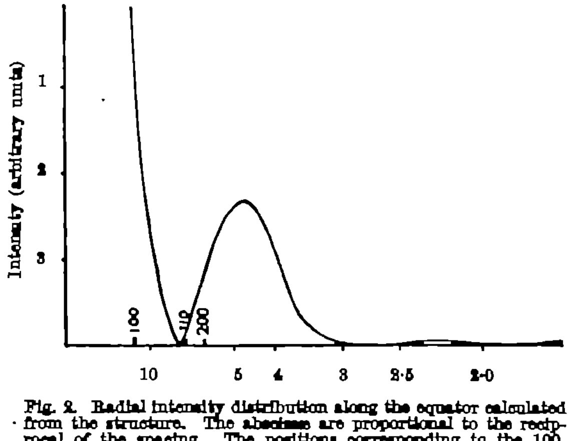

Fig. 2. Radial intensity distribution along the equator calculated from the structure. The abscissae are proportional to the reciprocal of the spacing. The positions corresponding to the 100, 110 and 200 reflexions of the hexagonal unit cell with $a$ = 12 A. are also marked

The recent infra-red data[6] of Sutherland *et al.* are also in agreement with the present structure. The expected dichroism of the non-coiled 3–10 helix agrees with the observed data[7], and the further coiling of this helix produces only small changes and the results are not materially different.

The distribution of the proline and hydroxyproline rings can be calculated exactly, and they are found to be such that the oxygen of hydroxyproline is nearly as far away from the axis of the cylinder as is possible. Thus internal hydrogen bonding of the OH in hydroxyproline is ruled out. Rather, these groups take part in linking the cylindrical rods with one another; the hydroxyproline OH group in one rod is nearly at the same level as the exposed non-hydrogen-bonded carbonyl oxygen of the neighbouring rod, so that they could readily be linked by a hydrogen bond. This is in agreement with the results of Gustavson[8] on the nature of the hydroxyproline OH . . . O bond. Assuming these bonds are 2·7 A. long, the distance between the centres of neighbouring rods works out to be 11·6 A., which is close to 12 A. (10·4/0·866) found for well-dried collagen[8]. The theoretical value is not precise, for it would change if the bond angles in the amino-acid residue and the α-carbon atoms are altered by even a small amount.

If the coiled coils described above are simply put together in a hexagonal array, then only some of the hydroxyproline OH groups are bonded to carbonyl oxygens of neighbouring rods. However, it is found that a very slight change in the pitch of the major helix is sufficient to make the number of hydroxyproline–carbonyl hydrogen bonds a maximum. Instead of a rotation angle (say φ) of 36° per three residues about the axis of the major helix, the angle must be changed to 35°. This immediately introduces a $6_1$ symmetry for the major helix, which now repeats after 216 residues (618 A.). The spacing 618 A. is highly suggestive of the 640 A. spacing found in the small-angle X-ray pattern and in electron micrographs of collagen. The condition for stabilization of the structure by forming the maximum number of hydroxyproline cross-links thus automatically leads to the long spacing of collagen. Further, on working out the number of hydroxyproline residues which occur in such a position that the hydrogen bonds are fairly short, the number is found to be twelve for every thirty-six of the *P* type residues. The percentage of hydroxyproline residues occurring in collagen is variable with the source of the material[9]; but if we assume that the hydroxyproline residues which actually occur are all hydrogen-bonded, then the maximum proportion of hydroxyproline residues should be 11 per cent. It is noteworthy that the maximum observed (namely, in bovine collagen) is about 10 per cent. Further, the correlation of the shrinkage temperature with hydroxyproline content reported by Gustavson[8] is also to be expected if hydroxyproline is mainly responsible for the cross-linking of the cylindrical rods. When collagen shrinks, the individual chains in the triple chain are not likely to be separated, but the triple chain itself would take up a highly folded configuration. The X-ray pattern of gelatin, in fact, supports this. The detailed evidence will be discussed elsewhere.

Having fixed the configuration of the rods with reference to hydroxyproline cross-linkages, a consideration of the length of the *R* side-chain of the third residue needed to form hydrogen-bonded linkages between one rod and another shows that it is variable from 5·5 to 7·5 A. In view of this, there must be a periodic distribution of the *R*-type residues. The details are not easy to work out, but an interesting result emerges, namely, that the distribution of *R*-groups along the fibre axis will not have a period of 618 A., but one-sixth of this. It is indeed noteworthy that electron micrographs of collagen stained with phosphotungstic acid exhibit[10] such a six-fold subdivision of the gross period of 640 A.

The agreement of 618 A. with 640 A. observed for dry collagen is not close enough, nor is the six-fold subdivision exact[11]. However, it must be mentioned that it is not at all certain that the unit cell of collagen is hexagonal. It is probably monoclinic even in the dry state with slightly differing *a* and *b* (taking *c* as monoclinic axis), as is found to be the case with wet collagen[12]. The subdivision of 618 A. would then not be exactly into six equal parts, and further the angle φ may be different from 35° and the macro-period may also differ from 618 A. The variation of the long spacing with moisture[9] is to be attributed to the changes in the angle of the monoclinic cell.

Further details of this work are reserved for a separate communication. [June 3

# ECOLOGY OF SNOWDONIA

## Ecology of Livestock Productivity

PHILLIPS *et al.*[1–3] have shown how climatic factors have a marked influence on livestock productivity in Wales. In Snowdonia[3], the mean estimated deadweights of ewes and lambs reaching the livestock collecting centres of the high-rainfall western section (precipitation generally greater than 100 in. mean annual rainfall) are less than those reaching Conway in the drier east (precipitation less than 100 in. mean annual rainfall).

A study[4] of summer grazing intensity over fifty-five sheepwalks (mainly enclosed) in Snowdonia (for the years 1945, 1948, 1949 and 1950) has shown that a significant difference, which can be attributed to rainfall differences, exists between eastern and western sheepwalks in the region. Western Snowdon sheepwalks (twelve in number) bear a mean grazing intensity of 1·27, while the eastern Conway Valley sheepwalks (forty-three in number) bear 1·94 ewe units to the acre[5].

It is, however, evident that factors other than those of climate do affect sheep grazing intensity in Snowdonia. The fifty-five sheepwalks have been classified into nine ecological groups. Some of these ecological groups are differentiated from each other by local climate, and others by soil and vegetational factors. An analysis of variance of the sheep grazing intensity over these sheepwalks shows that the main source of variation is due to ecological factors (variance ratio of 36·09 derived from ecological group and residual variances, based on 8 and 161 degrees of freedom)[4].

*Lower rainfall, Eastern Snowdonia* (Conway Valley section). Here soil and related vegetation have a major influence on sheep grazing intensity (see also refs. 6, 7). The highest sheep grazing intensity is found where (*a*) precipitation is less than 70–80 in. mean annual rainfall; (*b*) the soil parent material is either a basic Ordovician dolerite or pumice tuff, and the derived soil is akin to a brown earth; (*c*) soil drainage is free; (*d*) the vegetation is basically a *prato-Agrostideto-Festucetum* (an agrostis-fescue grassland in which *Trifolium repens*, *Dactylis glomerata*, *Plantago lanceolata*, *Achillea millefolium*, *Poa pratensis*, etc., are prevalent), typically distributed between 800 ft. and 1,450 ft. and locally 1,800 ft. O.D. Accruing from these investigations, much is known about the floristic composition of this kind of plant community; it varies much with local rainfall, soil properties (particularly exchangeable calcium) and grazing intensity[4,8].

Eleven such sheepwalks at the lower altitudes have a mean grazing intensity of 2·84 and three at higher altitudes 2·46 ewe units per acre.

Blanket peat areas, as would be expected, bear a much lower sheep grazing intensity (1·36 ewe units to the acre, a mean of five sheepwalks).

Acidic terrains with more podsolic soils derived from rhyolite and bearing a heathy vegetation are not prevalent in the Conway Valley. Only one major sheepwalk of this kind occurs there, and this bears a sheep grazing intensity of 1·70 ewe units per acre. It is difficult to assess the statistical significance of this, but the level of grazing intensity is according to expectation.

Glacial Drift, containing much basic igneous and volcanic materials (dolerites and pumice tuffs) under conditions of free drainage, gives rise to similar soils and vegetation, as do the dolerites and pumice tuffs *in situ*[3]. Impeded drainage abounds, however, and various *Nardus*, *Molinia*, *Juncus* and bog communities are prevalent. Such terrains on the average carry 1 ewe unit per acre less than the better kind of basic terrain (one group of eight such sheepwalks carried a mean of 1·70 and another group of thirteen 2·02 ewe units per acre). This contrast in sheep grazing intensity gives a measure of the possible increase in productivity following drainage.

*Higher rainfall, Western Snowdonia* (Snowdon section). In the Snowdon section it is possible to compare directly a number of sheepwalks on basic (pumice tuff and dolerite) and acidic (rhyolite) terrains. No statistical difference in grazing intensity exists between such terrains (basic terrains, mean of four walks, 1·39; acidic terrains, mean of eight walks, 1·21 ewe units per acre). Under the prevailing high rainfall conditions, the properties of soils derived from different parent rocks tend to merge, though vegetational differences persist[9]. Here, therefore, climatic factors are of paramount importance, and vegetational differences appear to have little influence on sheep grazing intensity.

The general conclusions that emerge from this study are:

(1) For the Snowdonia region as a whole, though environmentally complex, climatic factors, in particular rainfall, are the major influence determining livestock productivity estimated in terms of the number of stock per acre. These conclusions are similar to those of Phillips[3], who has considered productivity in terms of estimated dead-weight.

(2) Within the lower-rainfall Conway Valley area, geological and physiographical complexity affecting soil and vegetation have, however, an important bearing on livestock productivity, so that over a major part of Snowdonia, where precipitation is less than 70–80 in. mean annual rainfall, the basic igneous and volcanic terrains are of first importance to its livestock economy. Locally, even at higher rainfalls, these terrains are important grazing foci.

(3) The arctic–alpine element in the flora of Snowdonia is found mainly on these basic rocks. It is of interest to the problem of the conservation of this flora that it survives locally in the face of considerable grazing pressure. This needs detailed investigation.

(4) Environmental variations in an area like Snowdonia are of an extreme and complex kind. They are available within a single compact region and can provide a fruitful field of inquiry into fundamental ecological problems and also into animal productivity and health in relation to environment[4].

I am indebted to the Agricultural Research Council for financial help, and to Prof. R. Alun Roberts for his encouragement and facilities placed at my disposal. Part of the work outlined here was carried out at the School of Agriculture, Cambridge, and thanks are also due to Sir Frank Engledow for the facilities provided there for part of this investigation. A more detailed account of this work will appear elsewhere. A statistical appraisal of the results has already been given[4].

## Wild White Clover in Natural Mountain Grassland

IN the course of ecological investigations from Bangor, it has been found that there is a considerable number of outcrops of soft base-rich rocks distributed throughout Snowdonia which have a marked effect on the natural vegetation. The cliffs and crevices harbour an Arctic–Alpine flora and have been well described. On the slopes, however, there is an extremely different distinctive vegetation, a grassland scarcely distinguishable from lowland base rich grassland, about which little is known[1].

Cwm Llefrith, which is situated between Moel Hebog and Moel yr Ogof in South Caernarvonshire, is being investigated. This is related to a more general study of mountain grasslands by R. E. Hughes, preliminary details of which are given in the preceding communication. The upper reaches of this Cwm carry a very rich pasture in which wild white clover features prominently, though at 1,600–1,800 ft. in a rainfall of 100 in. The soil is a well-drained brown-earth type with a good crumb structure and very little undecayed organic matter, similar to those described in East Snowdonia by Hughes[2], the underlying rock being a magnesium-rich soft volcanic ash.

In pastoral Snowdonia, Cwm Llefrith is outstanding for the record of its productivity (Cwm Llefrith means milky cwm). Summer milk production used to be a prominent feature of its economy to the close of the past century. Every autumn about three tons of salted butter was taken from a single farm and sold at the slate-quarrying district of Blaenau Festiniog for winter use. Now under sheep, its carrying capacity is about two ewes to the acre, a capacity well above that of the surrounding districts. Hughes[1] reports a similar state of affairs elsewhere in Snowdonia. The basis of this remarkable productivity at such a high altitude seems to a great extent to be due to the abundance of wild white clover and the fertility of the accompanying sward.

From preliminary transplant experiments, a distinctive ecological race of wild white clover seems to have been differentiated, characterized by small size but extreme persistence, adapted to upland conditions of grazing and climate. Such a race is capable of enduring successfully the rigour of climatic conditions at high altitudes while lowland races are not. At the same time, it is likely that the mountain race shows some adaptation to low base content and low *p*H, since the soil in Cwm Llefrith, while it approaches that of lowland soil, is by no means identical with it.

The implications of such a situation are far-reaching in the economics of the reclamation and improvement of hill regions at the present state of our national economy, and make investigations on the ecology and genetics of wild white clover paramount in such regions.

## Role of Nucleic Acid and Enzymes in Peptide Chain Synthesis

RECENTLY, there has been much discussion of possible mechanisms whereby the order of the nucleotide sequence in a polynucleotide chain might determine the order of the amino-acid sequence in a peptide chain. The polynucleotide molecule is assumed to be the template or pattern for the peptide chain. In a mechanism proposed by one of us[1], enzymes were assumed to play an important part in attaching the amino-acids to the polynucleotide chain; as many enzymes would be required for this purpose as there are nucleotide combinations corresponding to amino-acids. In a system where a nucleotide triad is assumed to correspond to a given amino-acid, there must be as many enzymes as there are triads, and it can be shown that more than one triad would have to correspond to a given amino-acid in order to permit the occurrence of a reasonably large number of possible neighbours on either side of a given amino-acid in a peptide chain (unless it is postulated that there is to be no overlapping of the triads).

Since there are forty possible nucleotide triads, assuming direction along the polynucleotide chain to have no effect, or sixty-four triads if direction is important, there would have to be somewhere between forty and sixty-four specific enzymes to make the scheme in question function. While a synthesizing mechanism such as the one outlined could, once established, in theory produce these enzymes along with all the others for which nucleic acid templates existed, it is hard to understand how the mechanism could develop in evolution without the pre-existence of the forty to sixty-four operating enzymes just mentioned. Therefore it would seem of interest to explore possible mechanisms not involving the use of enzymes to attach the amino-acids to the nucleic acid template.

If enzymes do not attach the amino-acids to the template, the amino-acids apparently must be held by functional groups on the nucleic acid itself. An enzyme may function chiefly because of the exact geometrical relationships among its substrate-binding and catalytic groups, and hence it does not seem entirely unreasonable to assume that nucleic acid might act in a similar manner, especially since it possesses some of the same types of functional groups as are found on protein molecules. Such an idea has already in fact been advocated[2], although without much consideration of detail. The geometry of the ribonucleic acid molecule is not yet sufficiently known for one to decide whether the amino-acids could be bound by the functional groups of the purines and pyrimidines in the proper positions for attachment to phosphate groups, but one point in this connexion does seem fairly clear. This is that nucleotide triads could scarcely be expected to bind or determine the location of a given amino-acid in the absence of enzymes catalysing the process of attachment. This is because too long a segment of the polynucleotide chain is involved. On the other hand, it can be shown that too little information is stored in pairs of nucleotides, or diads, to account for the complexity of arrangement already observed in peptide chains, if one considers such diads in the way that has been customary up to the present time.

There is, however, one possible consideration which seems to have been overlooked, and in theory it could make possible the storage of enough information in nucleotide diads to account for the observed complexities of composition of peptide chains. This is that the rings of adjacent nucleotides (sugar, purine, pyrimidine) may lie close enough together to prevent free rotation about the bond connecting the sugar to the base. In this case a given base might have either one side or the other 'up' but not both, so that a new kind of geometrical isomerism would arise in the polynucleotide chain; this would greatly simplify the problem of information transfer from a polynucleotide to a polypeptide chain. This situation means that we would set up sixty-four different nucleotide diads, if direction along the polynucleotide chain were of importance. For example, we can start with diads containing adenine, with the ring 'up'. ('Up' and 'down' have no real meaning in this sense except to distinguish the two possible positions of the ring.) Let $A_u$ be adenine with ring up, $G_u$ guanine with ring up, $C_d$ cytosine with ring down, etc. The diad pairs are:

$$\begin{array}{ll} A_u—A_u & A_u—C_u \\ A_u—A_d & A_u—C_d \\ A_u—G_u & A_u—U_u \\ A_u—G_d & A_u—U_d \end{array}$$

It should be noted that this system would not function if the nitrogen of the purine or pyrimidine which is also attached to the sugar were of fixed optical configuration; but such a nitrogen usually does not maintain optical asymmetry. Coiling of the polynucleotide chain should not interfere greatly unless extreme.

With these sixty-four possible diads, it is in theory possible to assign three diad pairs to a given amino-acid and still have four left over. Since each assignment permits of eight possible neighbours for a given amino-acid on one side, the three assignments permit twenty-four possible neighbours, and the 'neighbour problem' disappears.

Such a system might require very few or possibly no enzymes, and would lend itself to attempts to explain the evolutionary development of protein synthesis. The system of assignments of nucleotide diads to given amino-acids might depend almost entirely on molecular geometry, and therefore should be the same throughout Nature as advocated by Dr. G. Gamow and collaborators (personal communication). The assignments should be susceptible of solution by an advanced study of the possible structures for ribonucleic acid. The most difficult aspect of the scheme seems to be to make it select from among the amino-acids glycine, alanine, valine, leucine, isoleucine and perhaps phenyl alanine, which do not have functional groups other than one carboxyl and an α-amino group; but any scheme would seem to face this problem. The scheme is very flexible, however, and could account for the change of a single amino-acid in a peptide chain or the transposition of two amino-acids only, whereas a scheme involving nucleotide triads presents difficulties in this respect. It is true that the system would require the presence of a polynucleotide-synthesizing mechanism that could distinguish and reproduce the 'up' and 'down' configurations of the bases, but such a system does not seem impossible to imagine. It should be noted that if the type of isomerism in question should be preserved in oligo-nucleotides produced by the action of ribonuclease on ribonucleic acid, it might be possible experimentally to find oligo-nucleotides of identical nucleotide sequences but with slightly different physical or chemical properties; although this might be difficult because of the large number of theoretically possible isomers even for a very short polynucleotide.

The senior author is indebted to Drs. G. Gamow, M. Ycas and A. Rich for the free communication of much of their thinking, which has been extremely helpful in bringing him up to date on the problem of the transfer of information.

This work was supported in part by research grant No. C994 from the National Cancer Institute, of the National Institutes of Health, U.S. Public Health Service.

## Role of Pantothenic Acid in the Reproductive Cycle of Ovaries in Fish

IN the course of an investigation of the vitamin contents of different organs of the tunny (*Thunnus thynnus*) caught off the coast of Norway, very high values were found for pantothenic acid in the ovaries, up to 245 μgm. per gm. of fresh tissue[1]. The tunny spawns in the Mediterranean and nearby waters in June and early July, whereupon shoals of the fish move in search for food and arrive off the coast of Norway in July–October. At this time the ovaries are small and in the first stages of a new reproductive cycle. Earlier observations in ovaries (hard roes) from different species of fish had indicated differences in the pantothenic acid content in relation to their degree of 'ripening', the values being lowest at the time of spawning. The findings in the ovaries from the tunny indicated a relation between the pantothenic acid in the ovaries and the sexual cycle of the fish. As cod (*Gadus morrhua*) of all sizes are brought alive to the fish market in Bergen all the year round, it was chosen as a suitable species for the further investigations.

Sivertsen[2] has investigated the spawning of the cod especially with regard to the yearly cycles of the regeneration of the reproductive organs. Based on his findings, ovaries from cod were collected during the period September–April, thus giving samples covering all stages of the development. The pantothenic acid concentrations were determined by the microbiological method using *Lactobacillus arabinosus* as test organism. The results are plotted logarithmically in Fig. 1, which gives the following general picture. In the ovaries of juvenile fish and of mature fish in the first stages of regeneration the pantothenic acid contents were high. Values up to 375 μgm. per gm. of fresh weight, 2,320 μgm. per gm. of dry weight were found, with an average of respectively 250 and 1,650 μgm. These values are in themselves of great interest as the highest reported pantothenic acid content found in natural sources. Pearson and Burgin[3] found that royal jelly, the special food given to those bee larvæ that are destined to become queens, contained an average of 183 μgm. pantothenic acid per gm. of fresh weight or 511 μgm. per gm. of dry weight. These values were the highest reported in Nature up to the present investigation. During the regenerative or reproductive growth of the ovaries in mature fish, the pantothenic acid content decreases, and finally it reaches values of approximately 10–30 μgm. per gm. of fresh weight shortly before spawning. In the very last stage of the reproductive cycle the ovaries take up considerable amounts of water, and after spawning the eggs contain only 5–10 μgm. pantothenic acid per gm. of fresh weight. The findings indicate that pantothenic acid may play an important part in the metamorphosis of the ovaries in fish.

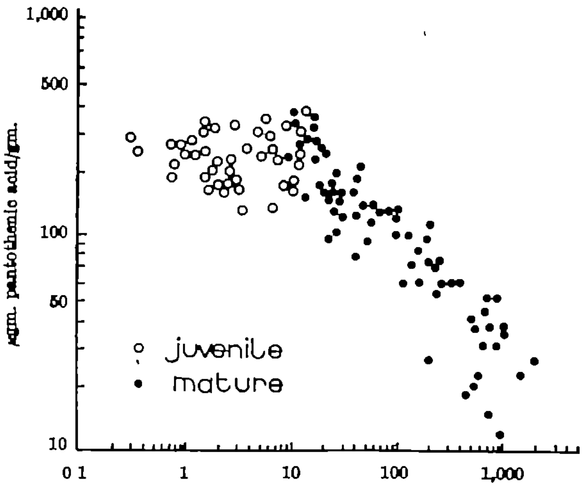

Fig. 1. Relation between pantothenic acid content and size of ovaries in juvenile and mature cod (*Gadus morrhua*)

Investigation of the contents of other factors of the vitamin B complex are in progress. Riboflavin and niacin did not show similar changes, while vitamin $B_{12}$ showed values decreasing from an average of 0·25 to 0·11 μgm. per gm. of fresh weight. Thus, of the factors so far investigated, only pantothenic acid shows the unique relation to the reproductive cycle reported above. The total dry matter of the ovaries increased from approximately 15 to 20 or 25 per cent during the growth of the ovaries; thus simple dilution effects are excluded. The results will be published in detail elsewhere.

## A Technique for studying the *In vitro* Effect of Serum on Activated Taeniid Hexacanth Embryos

THE *in vitro* effects of normal and immune serum on various nematode larvæ and on schistosome cercariæ have been described by a number of workers[1]. The use of helminth larvæ for the detection of natural and acquired immune responses has proved to be a very useful immunological tool, and some progress has been made towards using this method in the diagnosis of some nematode and blood-fluke infections.

The problem of applying this technique to the study of the host–parasite relations in cestode helminth infections is complicated by several factors. The penetrating larvæ of cestodes, the hexacanth embryos, particularly those belonging to the family Taeniidae, are contained within the several membranes of the tapeworm egg and are not readily available in a free and active state. The process of hatching and activating mature taeniid hexacanth embryos may be brought about under certain conditions by the use of appropriate enzymes and bile constituents[2]. The success of the hatching technique depends upon the selection of mature tapeworm eggs. It has been shown that naturally expelled tapeworm ova vary in their state of maturity[3], and for this reason, freshly obtained taeniid tapeworm eggs are stored in normal saline until hatching tests reveal that at least 30 per cent of the ova may be activated.

Only one previous worker has reported attempts to study the effects of sera on the penetrating larvæ of a cestode helminth. Chen[4], working with *Taenia taeniaeformis*, was not able to demonstrate any effect of rat immune serum on the hexacanth embryos. It appears from the description of his hatching technique that although he had obtained disintegration of the embryophores, the embryos contained within the oncospheral membrane had not been stimulated to activity and in consequence had not freed themselves from the oncospheral membrane. We have been studying the effects of calf and rabbit sera on the hexacanth embryos of *Taenia saginata* and *T. pisiformis* which have freed themselves from their membranes after activation, and have observed several types of serum reactions.

Our technique of hatching and activating the embryos has been previously described[2]. All operations are carried out in centrifuge tubes which are kept in a water-bath (38°–40° C.). Precautions are taken throughout to minimize the introduction of bacteria. After 30 min. treatment in the final activating solution, the embryos are sedimented by gentle centrifugation (1,500 r.p.m. for 1 min., centrifuge radius 5¼ in.), and the supernatant solution replaced with warmed (38° C.) normal saline. The embryos are rinsed in saline, sedimented and the saline replaced with 0·1–0·5 c.c. of the test serum. The serum and activated embryos are allowed to stand in the water-bath for 1 hr. before observations are made. Some reactions have been noted after only 15 min. Observation counts have been made at 1-, 2-, 3-, 4-, 5- and 6-hr. intervals as well as after overnight standing. Positive reactions are usually visible by one hour. Warmed ringed slides are used with a microscope stage warmer designed to keep the slide temperature at between 38° and 40° C. Only those embryos which have been successfully activated are counted in the observations.

Free activated hexacanth embryos may show several types of reactions. (1) Precipitates may form around the secretions of the penetrating gland and at other points on the embryos (Figs. 1 and 2). (2) A membrane may form enclosing the entire embryo and its secretions. (3) A lethal and lytic effect has been noted in inactivated immune sera and in some active and inactivated normal sera, particularly at the 3-hr. and later readings.

Oncospheral membranes that contain activated embryos which have not succeeded in freeing themselves may show a thickening precipitate on the inner surface of the membrane. This may be a result of the serum reaction to the embryo's secretions, and would appear to indicate that the serum-precipitating factor can pass through the semipermeable oncospheral membrane.

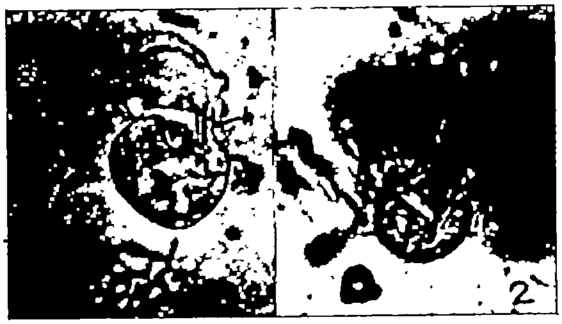

Fig. 1. A free and active taeniid hexacanth embryo in non-reacting serum which demonstrates the normal appearance of the gland secretions (*gs*) and hooks (*h*)

Fig. 2. A free and active taeniid hexacanth embryo in a reacting serum which demonstrates the thick precipitate reaction to the gland secretion (*gsp*) and the precipitates which form at the base of the hooks (*hp*)

Inactive oncospheres show a tendency to clump. This clumping occurs in all sera, however, and no other visible effects have been observed.

It is of interest to note the remarkable effect of serum in sustaining hexacanth embryos in an active state. Embryos may remain in a state of constant activity in sera for three hours or more, whereas in other solutions, such as intestinal juice or normal saline, activity usually ceases within one hour. Embryos kept on the bench overnight in normal inactivated serum may be reheated and reactivated again on the following day.

Studies are in progress using the technique described above to follow the development of immune responses in animals at various ages and at different stages of infection.

This work is being financed by a grant from the Agricultural Research Council.

## Nitrogen-containing Steroids in Aqueous Adrenal Cortical Extracts

Previous investigations on the nature of aqueous adrenal cortical extracts led to the isolation of potent fractions as assessed in the golden hamster maintenance test. A preliminary analysis of the crude fractions suggested the presence of nitrogen[1–3], and on further separation the potent mixtures yielded substances which according to our criteria possessed steroidal properties besides containing nitrogen. The course of the separation is outlined in Table 1.

A number of these substances could be isolated by combining various fractionation procedures such as counter-current distribution, paper electrophoresis, and paper chromatography. 13·0–36·5 per cent of the material gave a positive Zimmermann reaction in an early separation step; 18·4–43·9 per cent

Paper electrophoresis: NaOH +, $H_3PO_4$ +, N +, ninhydrin ±
paper chromatography: not uniform
Counter-current distribution of each fraction $\frac{CH_3OH/H_2O\ (80:20\ or\ 30:70)}{CCl_4/CHCl_3\ (1:1)}$
Several fractions
Paper electrophoresis: seventeen fractions NaOH +, u.v. max. 240 mμ $H_3PO_4$ blue, orange, yellow, brown or green ninhydrin +, N-content = 0·63–3·5 per cent

reacted as total neutral reducing lipids (Heard and Sobel). The nitrogen content varied between 0·8 and 4·5 per cent. The biuret and sometimes the ninhydrin reactions were negative, in contrast to the final fractions, which reacted strongly with ninhydrin. After electrophoretic separation most of the ninhydrin-positive bands also exhibited fluorescence with sodium hydroxide and phosphoric acid. Only a small number of ninhydrin-positive bands moved to the cathode; the rest, moving to the anode, did not always correspond to the steroid bands usually found here under our experimental conditions. Some of these bands were ninhydrin-negative.

A more detailed description will be given of six fractions which, out of a total of seventeen ninhydrin-positive fractions, have been assayed in the golden hamster maintenance test. All these fractions fluoresced with sodium hydroxide and phosphoric acid. Their nitrogen-content ranged from 0·63 to 3·5 per cent; in four of them it amounted to 2·59 – 3·50 per cent. If the mean molecular weight of the steroid component is taken as 300, this would agree with the theoretically calculated amount assuming that nitrogen is bound to the steroid nucleus in the form of an amino-acid or at most of an oligopeptide. According to the positive ninhydrin reaction and the anodic movement of the compounds, the carboxyl group as well as the α-amino-group should be present in a free state. Ultra-violet spectrophotometric analysis of the steroidal component showed an absorption maximum at about 240 mμ. This, together with the sodium hydroxide fluorescence, strongly indicates the presence of a $\Delta^4$-3-keto configuration. The fluorescing colours produced with phosphoric acid were equal to those shown by the biologically active corticosteroids[4].

Taking this evidence into account, it can be assumed that these substances are α,β-unsaturated 3-keto corticoids possessing an exocyclic additional amino-acid component. The presence of similar compounds in urine was recently reported by Eades *et al.*[5], and by Hudson and Lombardo[6]. The latter also suggested their presence in adrenal cortical extracts and adrenal vein blood. Nothing definite can as yet be said on the nature of the binding, though there is a possibility that a mechanism is involved comparable to the binding of steroids to protein as discussed by Areshkina *et al.*[7].

The large number of fractions isolated may be explained by supposing that these consist of different steroids and/or amino-acid components, though there is no doubt that in part the methods applied are involved, as the counter-current distribution in particular tends to show overlapping in closely adjacent fractions.

Whereas the total extract shows a strong activity in the life-maintaining assay, which is still present in the early fractions, no such activity was detectable with certainty in the six purified bands examined. It should be understood that by this bioassay only one property of certain steroids can be demonstrated, therefore no conclusions can be drawn from this test on the biological significance of our substances. Investigations are in progress to find out whether these substances represent a special hormone-group or merely a transport form, or whether they are intermediates in the biosynthesis of corticosteroids.

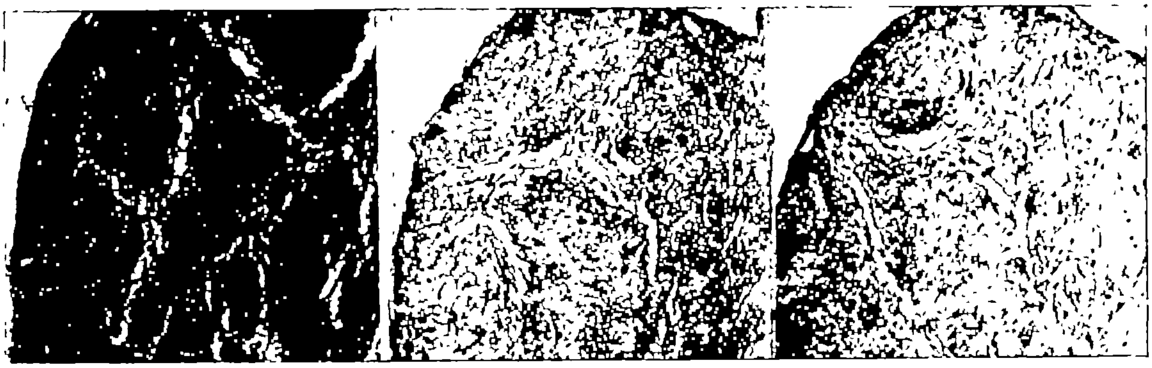
# Selective Digestion of the Neurosecretory Material of the Hypothalamus and of the Neurohypophysis by Tissue Homogenates

VARIOUS authors[1,2] claim, mostly on indirect evidence, that the neurosecretory colloid material present in histological preparations of the hypothalamus and in the neurohypophysis is related to the hormones of the posterior lobe of the hypophysis, probably to the antidiuretic hormone. However, Hild and Zetler[3] reported that some solvents extract the neurosecretory colloid material without modifying the antidiuretic activity.



(a) (b) (c)

Fig. 1. Neurohypophysis of *Bufo ictericus*; Gomori's chromalum hæmatoxylin stain (× 150): (a) incubated with distilled water; (b) incubated with liver homogenate, not heated; (c) incubated with liver homogenate, heated at 80° C. for 10 min.

Since various tissue homogenates were found to inactivate the antidiuretic action of posterior pituitary extracts[4,5], it appeared interesting to try the action of such homogenates on the neurosecretory colloid material.

We investigated the action of homogenates of various rat tissues—liver, spleen, lung, kidney, striated muscle—on histological sections of the hypothalamus and the hypophysis from dog, cat and from several species of *Bufo* (*B. arenarum*, *B. marinus*, *B. ictericus*).

One volume of the organ was homogenized with four volumes of distilled water in a Waring blender, and the solution centrifuged for 10 min. at 1,800 *g*. The *p*H of the supernatant was adjusted to *p*H 6·0–7·0 with *N*/4 sodium hydroxide and the solution was used either immediately or after heating for 10–15 min. at 80° C. or at 98° C.

The hypothalami and hypophysis were fixed for twenty-four hours in a saturated mercuric chloride solution containing 10 per cent formalin, embedded in paraffin and cut at 8μ. After removal of the paraffin, the sections were incubated with the homogenates for 4–5 hr. at 37° C. Control preparations were incubated in distilled water. After the incubation, both the control and the treated preparations were rinsed in running tap water for 5–10 min. and stained by one of the following techniques, which are known to stain the neurosecretory material: (*a*) chromic hæmatoxylin–phloxin method[6]; (*b*) Gomori paraldehyde–fuchsin as modified by Gastaldi[7]; (*c*) periodic–Schiff reaction[8].

In these conditions, we found that the colloid material cannot be demonstrated in the sections treated by the homogenates, although it remains unaltered in the control preparations.

According to Birnie[5], the homogenates which destroy the antidiuretic activity of posterior hypophysis extracts contain an enzymatic system that is inactivated by heating at 80° C. for 10 min. However, the homogenates heated at 80° C. and at 98° C. for 10 min. have the same action on the neurosecretory colloid material as untreated ones. Thus the action on the neurosecretory material appears to be different from the antidiuretic hormone-inactivating system previously described by Birnie.

Attempts to purify and to identify the active substance are in progress.

We tried the action of the homogenates on various organs of the rat (kidney, pancreas, intestine, stomach, adrenal, salivary glands, testicle, thymus) in the same conditions as those of the previous experiments. We found that no other histological element that stains by the Gomori methods is altered by this treatment. An exception is the beta cell granules of the islets of Langerhans of the pancreas, which can no longer be stained after this treatment. The significance of this finding will be studied elsewhere.

Thus the action of the homogenates on the Gomori-positive neurosecretory material appears to be specific. It is hoped that these properties may be used in order to provide a histochemical method to identify this substance.

## Glutamine as an Accelerator of Chondroitin Sulphate Synthesis

The sulphate exchange of chondroitin sulphuric acid can easily be studied *in vitro* in surviving slices of cartilage suspended in a Krebs–Ringer-bicarbonate solution containing $^{35}$S-labelled sulphate[1,2]. The influence of various factors on this reaction, which is of an enzymatic nature, has been studied in this department. In the course of the work, it was noted that small amounts of a liver homogenate added to the suspending medium produced a remarkable stimulation of the sulphate incorporation into chondroitin sulphuric acid. As reported in a preliminary paper[3], this effect was found to be due to the presence in the liver of a thermostable, dialysable factor.

In a subsequent study[4], it was found that this 'sulphate-exchange stimulating factor' is present not only in the liver, but also in several other organs and tissues, for example, brain, muscles and lung. It is also present in the serum of various animals. The sulphate-exchange stimulating factor from calf liver could be purified by means of fractional precipitation of boiled liver extract with mercuric acetate, and subsequent preparative paper electrophoresis. When subjected to two-dimensional paper chromatography, the final product showed seven ninhydrin-positive spots, one of which contained the whole sulphate-exchange stimulating activity.

In the course of the aforementioned investigation[2], our attention was directed to a recent paper by Lowther and Rogers[4] concerning the influence of glutamine on the synthesis of hyaluronic acid by bacteria. In it they also referred to the work of Leloir and Cardini[5] on the action of glutamine in the biosynthesis of glucosamine by *Neurospora crassa*. When we added glutamine to the series of compounds studied in the previous paper[3], it was found to have a five times greater sulphate-exchange stimulating activity per mgm. of dry substance than that of the electrophoretically purified sulphate-exchange stimulating factor from calf liver.

The evidence supporting the conclusion that the sulphate-exchange stimulating factor is probably identical with glutamine is as follows:

1. The sulphate-exchange stimulating – active ninhydrin-positive spot and L-glutamine have the same $R_F$ value in the solvents used for two-dimensional paper chromatography (80 per cent ethanol in water; *sec*-butanol–90 per cent formic acid–water: 75+15+10 parts, respectively).

2. In chromatography on the cation exchange resin 'Dowex 50', L-glutamine and the sulphate-exchange stimulating factor have the same effluent volume when tested separately as well as in mixed chromatography. The recovery of glutamine is not quantitative[6]; this also applies to the sulphate-exchange stimulating factor.

On the basis of the observations reported above, it seems likely that glutamine plays a part in the biosynthesis of mammalian mucopolysaccharides.

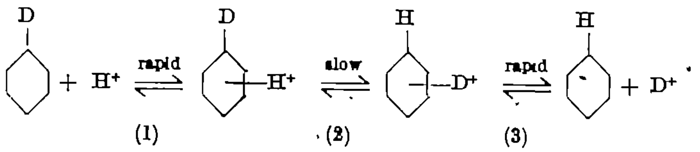
## Hydrogen Isotope Exchange between Aromatic Molecules and Aqueous Acids

THE hydrogen isotope exchange between an aromatic compound and aqueous acid without the intervention of heterogeneous catalysts can be regarded as an electrophilic aromatic substitution reaction[1]. It is also known qualitatively that the kinetic efficiency of the acid increases with its strength[2]. We have now examined quantitatively the nature of this dependence upon acidity in homogeneous solution at 25° and have drawn some more specific conclusions about the mechanism of the reaction.

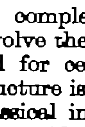
The compounds investigated were *ortho*-deutero derivatives of *p*-cresol, *p*-chlorophenol and *p*-nitrophenol, and monodeuterobenzene. The difference in reactivity of these compounds was such that exchange-rates could be measured in aqueous sulphuric acid over the whole composition range 9·2–97·6 weight per cent without a disturbing amount of sulphonation. Two of the compounds were also studied in aqueous hydrochloric and phosphoric acids.

The measurements indicate that, for each of the compounds, the logarithm of the rate-constant is linearly related to Hammett's acidity function[3] $H_0$, except at the highest acidities (higher than 85 per cent) where the increase of rate is less steep. There are minor discrepancies between the slopes of the log $k$ vs. $H_0$ lines and the ideal slope of $-1$, but these discrepancies are no greater than those found in the cases of other reactions which are held to satisfy this relation and they can be interpreted qualitatively[4]. We have also attempted to correlate the reaction velocities with the concentrations of the different proton donors present in concentrated aqueous acids, using results derived from the intensities of Raman spectra[5], but this alternative analysis of the data was unsatisfactory.

If we accept the usual interpretation of a linear relation between the logarithm of a rate-constant and $H_0$, our results point to the existence of a rapidly attained pre-equilibrium in which the aromatic molecule accepts a proton to form a conjugate acid in which the entering atom and the isotopic atom being replaced occupy non-equivalent positions. The rate-controlling step is then a rearrangement of this molecule, without intervention of the solvent:



By analogy with the case of aromatic nitration[6], it seems likely that step (2) proceeds via an intermediate in which deuterium and hydrogen occupy equivalent positions, that is,



Since the dependence of the reaction velocity on acidity is the same for benzene as for the substituted phenols, the proton attachment in the intermediate is probably of a non-classical kind, which we like to describe as 'outer complex'[7] formation. This outer complex may involve the same kind of bonding as has been suggested for certain of the so-called 'π-complexes'[8]. Its structure is likely to be analogous to that of the non-classical intermediate which has been postulated for the acid-catalysed hydration of isobutylene[9].

It must be left undecided for the present whether the reaction scheme put forward for the hydrogen isotope exchange will find a necessary place in the general theory of electrophilic substitution reactions or whether its applicability is to remain confined to substitution by protons.

A fuller presentation of the results and of the arguments leading to the conclusions outlined in this communication is being submitted for publication elsewhere.

## Mechanism of the Reduction of Tetrazolium Salts

INVESTIGATIONS undertaken since our previous publication[1] seem to permit of the following additional statements on the reduction and photochemical properties, respectively, of tetrazolium salts used as dehydrogenase indicators.

Alkalinity of the medium accelerates not only the disproportionation and chemical reduction of triphenyltetrazolium chloride, but also the oxidation of formazane. In a strongly alkaline medium all three reactions occur also in the absence of light, the presence of which is known to catalyse them considerably[1-6]. Heat and the presence of certain colloids, for example, gelatine, also increase the rate of these reactions. It was in the disproportionation and chemical reduction of triphenyltetrazolium chloride that the accelerating effect of gelatine could be observed.

Under the appropriate experimental conditions, the chemical reduction of triphenyltetrazolium chloride to formazane, for example, by the action of ascorbic acid, takes place in a strongly acid medium as well.

The common explanation suggests itself for all these phenomena that the acceleration of these reactions is based on diminishing the activation energy and increasing the reversibility. The effect of gelatine, slightly reminiscent of that of the enzymes, can be explained as follows: a significant part of the activation energy required is furnished by the energy liberated on the adsorption on the gelatine particles of formazane, one product of the reaction. Measured polarographically, its value was about 10 kcal. The reversibility-increasing action of heat and alkalinity could also be shown polarographically. At 20° C., the triphenyltetrazolium chloride $\rightleftharpoons$ formazane system was only found to be quite reversible above $pH = 14$. At lower $pH$ values the irreversibility (the difference between the oxidation and reduction potentials) increased.

Polarographic study of 'photo-triphenyltetrazolium chloride', the final product formed by disproportionation of triphenyltetrazolium chloride on the action of light, has shown: (1) that its polarographic reduction occurs by four electrons, analogous to that of triphenyltetrazolium chloride, but at a more negative reduction potential; (2) that the diffusivity of 'photo-triphenyltetrazolium chloride' is twice that of triphenyltetrazolium chloride in spite of their almost identical molecular weight; the phenyl groups attached to the nitrogen atoms 2 and 3 are forced in the 'photo-triphenyltetrazolium chloride' into a plane; (3) that the polarographic reduction of 'photo-triphenyltetrazolium chloride' results not in the free radical which Kuhn and Jerchel[7] obtained by chemical reduction, but primarily a labile 9-atomic heterocycle is formed, and this is transformed by a secondary reaction into the free radical.

The photo-oxidation of formazane is catalysed not only by its final product (autocatalysis), but also by other fluorescent compounds, showing that autocatalysis is based upon fluorescence. The oxidation of formazane in darkness in alkaline medium is likewise autocatalytic in character; but the catalysis is of a quite different nature: in alkaline medium the 'photo-triphenyltetrazolium chloride' formed as the final product is quickly dismembered with the uptake of hydrogen. The latter is furnished by the as yet unchanged formazane, while this is being oxidized.

In an alkaline medium, disproportionation of triphenyltetrazolium chloride yields in addition to 'photo-triphenyltetrazolium chloride' chiefly formazane, and in an acid medium mainly the colourless 1,2-dihydro-triphenyltetrazolium chloride, exactly the same as in the polarographic reduction of triphenyltetrazolium chloride[10]. In addition, we have studied the behaviour of two ditetrazolium compounds, that of blue tetrazolium and neo-tetrazolium, and found the following:

(1) Their polarographic reduction was analogous to that of triphenyltetrazolium chloride, but many more anomalies could be observed than with the latter.

(2) Light had no catalytic effect on their chemical and enzymatic reduction and disproportionation. Strong alkalinity resulted in their disproportionation; gelatine accelerated their chemical reduction.

(3) Alkalized very carefully in the presence of ascorbic acid, an alcoholic solution of blue tetrazolium becomes red, as a small portion of blue tetrazolium transforms into its red monoformazane readily soluble in water, alcohol or benzene. Under the action of light, benzene solution turns yellow, obviously in connexion with a *cis-trans* transformation[9]; in darkness it turns red again. The diformazane of blue tetrazolium, on the other hand, turns in the light from blue to red, likewise reversibly.

(4) Triphenyltetrazolium chloride, ditetrazolium-salts and 'photo-triphenyltetrazolium chloride' exhibit catalytic polarographic waves.

The details of our results will be published elsewhere[11].

## Separation within the Homologous Series of *n*-Alkyl Sulphates, *n*-Alkyl Pyridium and *n*-Alkyl Trimethyl Ammonium Halides by Paper Chromatography

Methods have been described for the identification of synthetic detergents in admixture with three or four dyestuffs utilizing an ascending chromatogram[1,2]; but these procedures do not allow the separation of mixtures of detergents, neither do they permit the separation of members of a homologous series.

Work carried out in these laboratories has clearly shown that it is possible to effect a complete separation of the normal saturated alkyl sulphates when the adjacent members differ in chain length by two carbon atoms. Mixtures of *n*-octyl, *n*-decyl and *n*-dodecyl sulphates have been separated by ascending paper chromatography using 15 per cent aqueous ethyl alcohol, while 40 per cent aqueous ethyl alcohol has been found effective in separating mixtures of *n*-tetradecyl, *n*-hexadecyl and *n*-octadecyl sulphates. The chromatograms were run at 30° C. using Whatman No. 1 paper.

The position of the spots of the anionic material can be shown by spraying with an aqueous solution of pinacryptol yellow after drying in a current of warm air. When the sprayed chromatogram is examined under ultra-violet light the spots of anionic material fluoresce a bright orange on a pale yellow background. The minimum amount of material capable of detection by this means is of the order of one microgram. Preliminary tests have indicated that this method of separation is applicable to other classes of sulphated and sulphonated detergents.

A parallel investigation of cationic materials has indicated that paper chromatography is capable of effecting the separation of the homologous series of *n*-alkyl pyridinium halides and also the *n*-alkyl trimethyl ammonium halides. The ascending chromatogram of these materials is carried out at 30° C. using 30 per cent aqueous ethyl alcohol containing 5 per cent of concentrated hydrochloric acid. The position of the spots of cationic material is shown by spraying the air-dried chromatogram with an aqueous solution of rhodamine *BS* containing a commercially available optical bleach. The sprayed chromatogram is then exposed to ammonia vapour to neutralize any mineral acid present and examined under the ultra-violet lamp. The spots of the cationic material are seen to fluoresce a bright vermilion on a white background. The method is sensitive to approximately one microgram of cationic material.

It will be appreciated that these methods allow the differentiation of other classes of organic compounds which by means of chemical reaction may be converted to surface-active compounds of the above-mentioned types.

Further investigations on the qualitative and quantitative aspects of the paper chromatography of other classes of anionic and cationic compounds continue, and the results will be published elsewhere at a later date.

## Reproduction of Mumps Virus in the Chorio-allantoic Membrane

Little is known about the reproduction cycle of mumps virus. This seems strange, as some of the techniques available for influenza virus should be applicable to this virus, which is in many ways similar in its reactions. The method introduced by Hoyle[1,2] in his study on the multiplication of influenza virus in egg membranes, however, did not yield clear-cut results with mumps virus. The main difficulties were the slow adsorption of the virus to the reproductive cells, the relatively high proportion of free (vital) virus particles not taking part in the reproduction process during the experiments and the relatively low reproduction velocity. This last factor made it necessary to expand the experiments to more than thirty hours, and consequently the experiments had to be divided into many parts. The comparability of the infection-, hæmagglutination- and other titres is impeded by this division of the experiment.

In five series of experiments eggs were inoculated with 0·1 ml. of a dilution of freshly harvested allantoic fluid of the mumps strain 'Enders'. To measure the infection titre of the inoculum a series of tenfold dilutions was made and three eggs were injected with 0·1 ml. of each dilution. Every half-hour after the infection the allantoic fluids of four eggs were tested for hæmagglutination power, and the chorio-allantoic membranes were harvested. These membranes were ground with quartz sand and brought into suspension with saline (containing penicillin and streptomycin). A series of tenfold dilutions was made and with each dilution three eggs were inoculated. With the same material the amount of complement-fixing antigen was measured. As the whole series of experiments could not be carried out at the same time the series was cut into parts of four hours each. With each part a reference test was carried out half an hour after the inoculation of the eggs.

The following results were obtained (Fig. 1).

Complement-fixing antigen could not be detected before 18½ hr. from inoculation.

Hæmagglutinin did not appear before 19½ hr. from the beginning of the experiment.

Infective material remains detectable throughout the experiment. The infection titre decreases from 2½ hr. after inoculation until it reaches a minimum after 5 hr., to remain low until 14½ hr. after injection. From then onward infection titres increase very slowly. No secondary phase of decrease of infection titres can be detected within 30 hr. The absence of complement-fixing antigen between 21½ hr. and 28 hr. after the beginning of the experiment may be due to technical error. Hæmagglutinin titres show a steady increase not followed by a secondary decrease.

In consecutive experiments the above-mentioned results could not always be repeated. In the case when the initial infection dosage was low no hæmagglutinin or complement-fixing antigen could be detected. In the case when the initial infection dosage was high ($10^5$ or more), no decrease in infection titre was detectable and the gain in infectivity-rate was relatively low.

In order to get more clear-cut results, we used another experimental arrangement. Chorio-allantoic membranes of nine days old chick embryos were cut into a great number of pieces each of about 0·01 sq. in. After washing in saline, the pieces were put into a Petri dish containing a mumps virus suspension in saline (infection titre $10^{-3}$–$10^{-4}$). After twenty

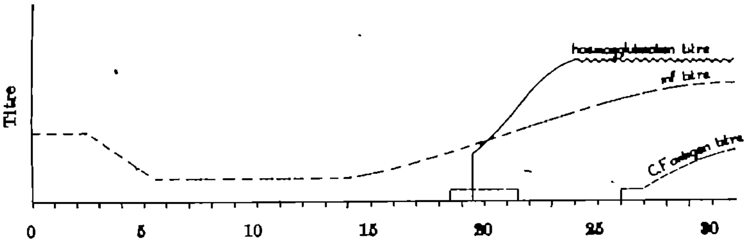

Fig. 1. Multiplication of mumps virus in the chorio-allantoic membrane of incubated hen's eggs

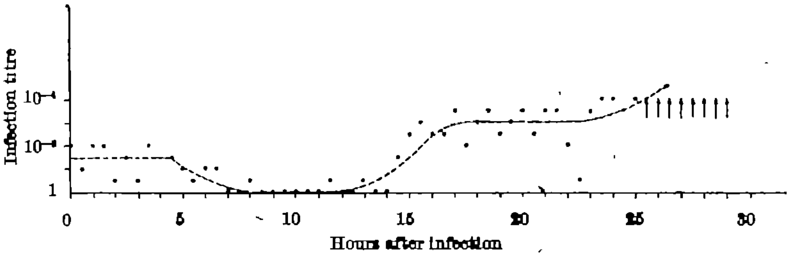

Fig. 2. Virus culture in surviving chorio-allantoic tissues; typical experiment

minutes the pieces were rinsed one by one in several Petri dishes containing saline and then put into roller tubes each containing 1 ml. Tyrode suspension with 400 units penicillin, 0·25 mgm. (0·04 grain) streptomycin, embryo extract and fowl serum. They were then incubated at 37° C. Each half-hour the pieces of membrane from three tubes were ground in a mortar and a suspension was made by adding 0·5 ml. saline (+ penicillin and streptomycin). Tenfold serial dilutions were made and eggs were injected with it and incubated for four days. The results of a typical experiment are demonstrated in Fig. 2.

Mumps virus, we may conclude from these experiments, is reproduced in the living chorio-allantoic cell in about 14–17 hr. The gain in infection titre after such a period is about thirty times the initial amount of virus.

This work was aided by a grant from the (Dutch) National Health Research Council (T.N.O.).

## *Trichomonas hominis* cultured without Bacteria

*Trichomonas hominis*, like most other intestinal parasites[1], is usually cultured *in vitro* in a Dobell–Laidlaw biphasic medium (horse serum, rice starch and Ringer's solution to which is added 15 per cent liquid horse serum)[2]. Growth of *T. hominis* in that medium occurs only when associated with bacteria. At 25° C. the equilibrium between bacteria and protozoa is optimum, and after forty days of incubation, *Trichomonas* are still numerous and lively. In such conditions, the maximum protozoal concentration attained is about 200,000 cells/c.c.

For the maintenance of the strain, this association is indeed advantageous; in the same way, Sorel[3] pointed out that *Trichomonas vaginalis* lives longer when associated with fungi of the genus *Candida* than in pure culture. Hitherto, attempts to grow *T. hominis* without bacteria have been unsuccessful. Recently, McEntegart[4], who was working with pure strains of *Trichomonas vaginalis*, *T. foetus* and *T. gallinarum*, confirmed in one of his papers that *T. hominis* cannot grow without bacteria.

These characteristics suggested to other investigators that the parasite might be cultured by techniques used for the growth of *Endamoeba histolytica* without development of bacteria. *T. hominis* was cultured by Shaffer and Biegeleisen[5] in a medium 'preconditioned' by the growth of an anaerobic Gram-negative streptobacillus, removed afterwards by centrifugation. In fact, the behaviour of *T. hominis* and *E. histolytica* is not substantially the same, and growth of the flagellate depends on bacterial growth only when it is cultured in a medium of the Dobell–Laidlaw type.

Working with a strain of *T. hominis* (T.H. strain), kindly sent to me by Prof. L. Lamy from the Institut Pasteur of Paris, I was able to separate *T. hominis* from bacteria by changing the culture medium. At 37° C. in complete media, like *CPLM*[6], or in the media used by McEntegart[7] and Feinberg[8], associated bacteria grow abundantly and destroy *T. hominis* in 24 hr., as was pointed out by Williams *et al.*[9] for *T. foetus*. However, addition of 1,000 µgm./c.c. of streptomycin and 1,000 u./c.c. of penicillin allows the growth of *T. hominis* in these media. After three serial transfers in *CPLM* medium to which these antibiotics have been added, sterility tests in bacto-thioglycolate medium show that *T. hominis* is free from bacteria. The pure strain has been maintained by us for four months, with three-week serial transfers. In these conditions, *T. hominis*, like *T. vaginalis*, attains a concentration higher than two million protozoa per c.c.

The parasite cannot grow further without bacteria in Dobell–Laidlaw medium, even if cysteine or ascorbic acid has been added to it, in order to allow the growth of anaerobic micro-organisms. On the contrary, it grows well if it is re-associated with the original bacteria, or with pure strains of bacteria, like *Streptococcus faecalis* A.T.C.C. 6057, and *Escherichia coli* 120 of our collection.

## Nitrogen Fixation in Detached Non-legume Root Nodules

Previous work has shown that the fixation of nitrogen normally characterizing the root nodules of *Alnus*[1,2] continues after detachment of the nodules from the plant to an extent sufficient for its detection by isotopic technique[3,4]. Bond[4] has shown that the fixation per unit of total nodule nitrogen was considerably greater in such detached nodules from young *Alnus* plants than in detached legume nodules.

Another non-legume possessing nitrogen-fixing root nodules is *Myrica gale*[1,4,5], and the results of isotopic tests with detached nodules of this species are given in Table 1. They show that here also fixation continues to a readily detectable extent.

Table 1. Fixation in Detached *Myrica* Nodules

| | Sample No. | Nitrogen-15 content, atom per cent of total nodule nitrogen |
|---|---|---|
| Exposed to excess nitrogen-15 | 1 | 0·426 |
| | 2 | 0·468 |
| | 3 | 0·468 |
| | 4 | 0·403 |
| | 5 | 0·433 |
| | 6 | 0·463 |
| Controls, exposed to air | 7 | 0·380 |
| | 8 | 0·379 |

Samples (0·5 gm.) of nodules from water-culture plants were placed in specimen tubes (14 ml.) and these then charged at 1 atmosphere with a mixture containing 20 per cent oxygen and 80 per cent nitrogen (with 18 atom per cent nitrogen-15). The nodules were held at 21° C. for 24 hr. and then assayed for fixed nitrogen-15 in the usual way (ref. 6).

In further studies of detached *Alnus* nodules the effect of oxygen supply on fixation and also some features of respiration have been examined. The results in Table 2 show that the fixation (which is proportional to the increase in nitrogen-15 content) is markedly sensitive to oxygen supply. Analysis of variance confirms that the over-all oxygen effect is highly significant, although the differences between means do not all attain the magnitude required for significance (0·043 atom per cent, $P = 0·05$). For various reasons, one of which is the rapidity of nodular respiration (see below), it is difficult to avoid a substantial fall in oxygen supply during such an experiment, so that over the experimental period as a whole the range of mean oxygen supply was considerably smaller than that provided initially.

Fig. 2. Effect of Oxygen on Fixation in *Alnus* Nodules

| | Oxygen initially supplied (per cent) | | | |
|---|---|---|---|---|
| | 21 | 12 | 5 | 1 |
| Mean increase in nitrogen-15 content, atom per cent of total nodule nitrogen | 0·141 | 0·083 | 0·054 | 0·032 |

Four samples (0·6 gm.) of nodules from young water-culture plants were set up at each oxygen-level in specimen tubes afterwards charged at 1 atmosphere with oxygen/nitrogen mixtures containing 20 atom per cent nitrogen-15. Further treatment was as for *Myrica* nodules. The data show increases over the normal figure of 0·372 atom per cent.

The mass spectrometric analyses on which Table 2 is based were carried out on the whole of the nodule nitrogen; the inability of Virtanen *et al.*[3] to detect fixation satisfactorily in detached *Alnus* nodules except by analysis of the soluble fraction only was probably due to their use of nodules from older plants. Calculation shows that in the present experiment the total fixation (nitrogen-14 and nitrogen-15) per sample exposed initially to 20 per cent oxygen was 0·03 mgm. Exposure of nodules to initially 40 per cent oxygen resulted in a marked reduction of fixation, but at present the possibility cannot be excluded that this was due to the reduced nitrogen supply.

In measurements by the Warburg technique, the mean $Q_{O_2}$ (cu. mm. oxygen consumed per hr. per mgm. dry weight) for nodules from first-year *Alnus* plants was 10·5 at 24° C., the nodules being bathed in a nitrogen-free mineral culture solution in an atmosphere of air during the measurements; the corresponding $Q_{O_2}$ for the roots of the same plants was 3·5. Thus such nodules show rapid respiration, both in comparison with the roots that bore them and with a majority of plant tissues. In nodules from second-year plants the mean $Q_{O_2}$ had fallen to 2·0. The $Q_{O_2}$ of nodules falls steeply when the oxygen supply is reduced from the air level, as shown in Table 3, the response in root tissues being considerably slighter. The effect of higher oxygen supply on respiration has not yet been tested.

Table 3. Respiration of *Alnus* Nodules and Roots

| Oxygen supplied (per cent) | Mean $Q_{O_2}$ of nodules | Mean $Q_{O_2}$ of roots |
|---|---|---|
| 21 | 2·72 | 1·03 |
| 12 | 1·86 | 0·80 |
| 5 | 1·14 | 0·64 |
| 1 | 0·35 | 0·33 |

Three samples of nodules or root portions from 2nd-year plants were set up in each oxygen/nitrogen mixture, measurements being continued for four hours, during which time the respiration remained essentially steady. Difference required between means for significance = 0·43 for nodules, 0·08 for roots ($P = 0·05$).

Though comparison of the oxygen effects on fixation and nodular respiration is hindered by the drift in oxygen supply in the fixation experiment, the data show that both processes are markedly and perhaps similarly affected by reduction of oxygen supply. The possibility which thus arises that the two processes are closely linked will be further investigated.

We wish to thank Dr. R. I. Reed for kindly carrying out the mass-spectrometer analyses.

## Secretion of a Highly Sulphated Acid Mucopolysaccharide by the Brittle-star, *Ophiocomina nigra*

The secretion of a mucus from the tube-feet of ophiuroids is well known[1], although the chemical nature of this substance has not been investigated. In a study of the feeding mechanisms of ophiuroids, I find that *Ophiocomina nigra* (Abildgaard), a common littoral species widespread in the north-east Atlantic and Mediterranean, in addition to the mucin of the tube-feet, secretes all over the body surface an abundant mucus used in conjunction with a detritus-feeding mechanism. Attempts to find the source of this secretion have revealed two types of mucus glands previously undescribed for the species.

(*a*) Large numbers of unicellular glands are distributed over all the general body surface. Histochemically, their secretion gives the general reactions of a simple acid mucopolysaccharide.

(*b*) In addition, there are massive glands within the calcareous structures covering the body, best developed within the lateral arm spines. The mucus within the arm spine is massed along the aboral aspect of a nerve cord which occupies the central longitudinal axis of the spine. These glands open to the exterior along the aboral and lateral surfaces of the spine by means of regularly spaced ducts lined with squamous epithelium. The mucus arises from numerous dense granular areas lying irregularly along the nerve strand. One to several nuclei can be seen in each patch, with no clear cell boundaries separating them. Such multi-nucleated glands have been found within the upper, lower and lateral arm plates, in the tentacle-scales, oral shields, oral papillæ, and in the tubercles of the disk, as well as within the arm spines. In every case, a distinct nerve tract is in association with the granular source.

The secretion product of these granular patches when stained with toluidine blue exhibits an intense γ-metachromasia, and gives a weakly positive Millon reaction; it is negative to the periodic acid – Schiff reaction and to sudan black *B* applied to frozen sections. It is stable to incubation in commercial testis hyaluronidase, and to various extraction techniques for ribonucleic acids. It has a methylene blue extinction point below *p*H 0·65, lower than that of the mouse mast cells used as controls.

The tube-foot mucin of this species gives identical histochemical reactions.

These results characterize the mucus in question as a highly sulphated acid mucopolysaccharide, similar in nature to fully substituted heparin. A similar epithelial mucin, 'mactin *A*', has been described from the labial palps, gills and inner mantle surface of the bivalve mollusc, *Spisula solidissima*, extracts of which have a strong blood anti-coagulant action[2]. The jelly coat of sea-urchin eggs is known to contain a highly sulphated acid mucopolysaccharide, allied to the connective tissue mucins[3].

Among other species of British Ophiuroidea examined so far, glands secreting a highly sulphated acid mucopolysaccharide have not been found in *Ophiothrix fragilis* and *Ophiura texturata*. *Amphipholis squamata*, however, has within its arm spines glands which, though somewhat different anatomically, secrete a mucus histochemically identical with that of *O. nigra*. These glands are the subject of a considerable body of recently reviewed literature[4], as they are considered to be the source of the phosphorescence for which the species is noted. The phosphorescence of other ophiuroid species is attributed to similar gland cells known to be intensely basophilic.

A full report of this work will be published elsewhere.

## Cytoplasmic Nodules in the Endosperm of some Cucurbitaceae

Cytoplasmic extensions of definite shape growing into the embryo sac during endosperm development have been termed cytoplasmic nodules or vesicles. They are of two types, nucleated and non-nucleated. Nucleated nodules are reported in *Impatiens roylei*[1], *Isomeris arborea*[2] and *Musa errans*[3], while non-nucleated nodules occur in *Oldenlandia corymbosa*[4], *Pennisetum typhoideum*[5] and *Stackhousia linariaefolia*[6]. Billings[2] has reported the development of the embryo from the nucleated nodules in *Isomeris arborea*. Maheshwari and Sachar (unpublished work) have, however, contradicted this and find that the embryo arises from the egg as in other angiosperms. Farooq[4] has reported in *Oldenlandia corymbosa* that these nodules become detached from the general cytoplasm and ultimately degenerate, but I do not agree with him (see below).

The present investigation shows the occurrence of non-nucleated nodules in *Cyclanthera explodens* Naud., *Herpetospermum caudigerum* Wall., *Sechium edule* S.W. and a hermaphrodite variety of *Luffa acutangula* Roxb. Slides of *Cyclanthera explodens* were passed on to me by Prof. Bahadur Singh, while the material of *Herpetospermum caudigerum* and *Sechium edule* was collected from Darjeeling and that of the hermaphrodite variety of *Luffa acutangula* from the Botanical Gardens, B.R. College, Agra.

The endosperm is free nuclear and—in early stages its cytoplasm with free endosperm nuclei—forms a peripheral lining of the embryo sac, with a central vacuole. As the endosperm grows, a balloon-like bulging with a lining of cytoplasm arises in the micropylar region. More protuberances arise in it from the cytoplasm, forming the base of the later bulge (Figs. 1 and 2). These protuberances acquire definite shape and resemble nodules or vesicles described by the authors mentioned above. They are hollow and non-nucleated like the primary cytoplasmic bulging. Endosperm nuclei advance into the primary bulge, being followed later by the formation of more nodules on it (Fig. 1). Cytoplasmic nodules also arise laterally in the vacuole of the embryo sac. All nodules fuse to fill up the space and finally mix with the general cytoplasm. After the fusion of the nodules has taken place, endosperm nuclei advance into the resulting cytoplasm. Any space left in this cytoplasm is further filled up by the formation of fresh nodules (Fig. 3) and finally the whole of the endosperm becomes cellular. Since

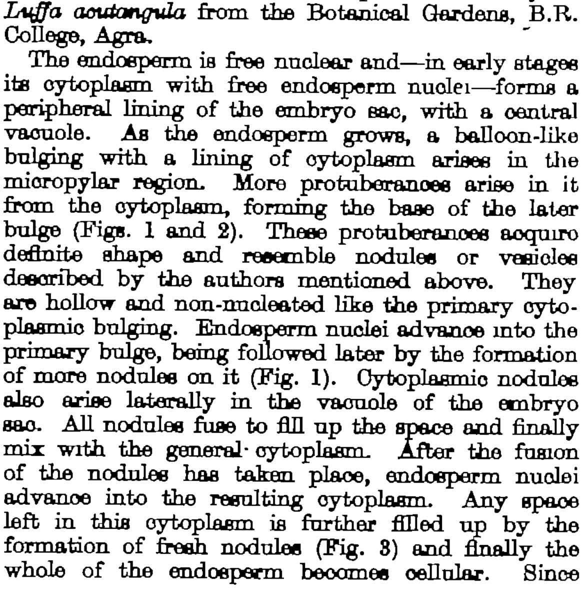

Fig. 1. Longitudinal section of the embryo sac of *Luffa acutangula*; × 300. Fig. 2 Endosperm of *Sechium edule*; × 220. Fig. 3. Embryo sac of *Herpetospermum caudigerum*; × 140. *cn*, cytoplasmic nodules *cv*, central vacuole, and *pcb*, primary cytoplasmic bulge

nodules in Cucurbitaceae show greater chromaticity, belated fusion and ultimate mixing with the general cytoplasm, their detachment, degeneration and disappearance in *Oldenlandia* need confirmation.

I thank Prof. Bahadur Singh for guidance, Prof. P. Maheshwari for kindly going through my slides and Dr. R. L. Paliwal for help. For financial assistance, I thank the Government of India for the grant of a junior research training scholarship.

## Biosystematics of the *Sisymbrium irio* Complex

*S. irio* Linn. is a polytypic winter annual which grows throughout the Panjab plains. It occurs in diploid, triploid, tetraploid, hexaploid and octoploid races. All these races get considerably modified in response to varying amounts of moisture and sunlight. The phenotypic plasticity has been studied experimentally using the conventional 'water-light' gardens.

The diploid is morphologically uniform and shows seven bivalents. Its artificial autotetraploid shows quadrivalents and does not resemble the natural tetraploid. The latter possesses two ecological races which are markedly different from the diploid. At meiosis it has always fourteen bivalents. It is a genomic alloploid, which is confirmed by the presence of fourteen univalents in its polyhaploid. The triploid is morphologically somewhat akin to diploid but differs in details of leaf shape, flower size and above all in being completely sterile. It is a natural hybrid between diploid and tetraploid. At meiosis it shows seven to eight bivalents plus seven to five univalents. Evidently one of the genoms of the tetraploid is homologous with the diploid. Such plants yield only five to six seeds in strong contrast to the production of several thousand by the parents. Generally these seeds are of hexaploid constitution. The hexaploid is morphologically like the triploid except that it has bigger flowers and long fertile siliquas. At meiosis there are almost always twenty-one bivalents, but at times there are one to two quadrivalents. The octoploid is morphologically somewhat akin to tetraploid. However, it differs from the tetraploid in possessing shorter and thicker stems and fruits and bigger and thicker leaves, flowers and seeds. It shows varying numbers of quadrivalents and bivalents.

Crosses were attempted in all directions, but so far no hybrids except the triploid have either been obtained or seen in Nature. The hexaploid and octoploid have been synthesized. The former is either auto-allo or segmental alloploid, while the latter is auto-alloploid. It is concluded that, in this complex, one of the basic genoms is either the same as that of the diploid or of some form very close to it. The other genom has not been discovered yet.

Identifications carried out at the Forestry Research Institute, Dehra Dun, and Kew Herbariums reveal that all the races are taxonomically under the same species—*S. irio* Linn. Comparison of the various races was very kindly made by Dr. N. Y. Sandwith with the Linnean type material. It has become clear that only the hexaploid race compares very well with the Linnean holotype (Sheet No. 836.35) collected from Spain. These resemble each other in fruit characters, but differ in number of lobes of leaves.

The species has a very wide distribution covering the whole of Europe and extending to the north-western Indian sub-continent. So far it has been possible to study it in Panjab (India) primarily from Amritsar and nearby areas within a radius of approximately fifty miles. For any clear understanding of the variation pattern of the *irio* complex it is imperative to study it from most of the areas of its range.

I would be very grateful to the botanists in the area who are in a position to help me by sending seed samples, if possible accompanied by herbarium sheets giving pertinent information. Furthermore, seed samples of any other species of the genus *Sisymbrium* and allied genera like *Alliaria*, *Arabidopsis*, *Descurainia* and *Eutrema* would also be most welcome.

The details of the investigation involving morphological, cytogenetical, ecological and taxonomical aspects of the problem will be published in due course.

I am indebted to Profs. P. N. Mehra, G. L. Stebbins, jun., R. C. Rollins, K. N. Kaul, Drs. N. Y. Sandwith, W. B. Turrill and Father H. Santapau for their encouragement and valuable help.

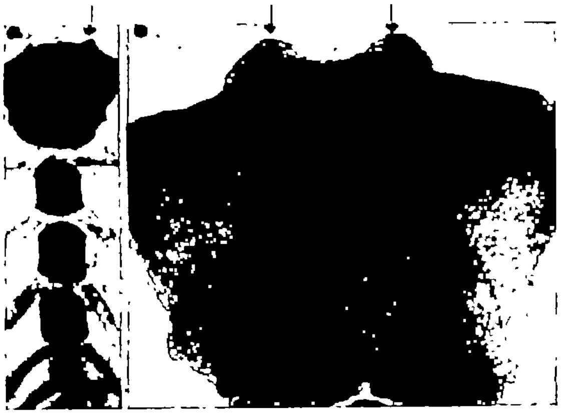
## Supra-sternal Ossicles in Primates other than Man: some Isolated Cases in Gorilla and Chimpanzee

SCHULTZ[1] examined nearly three hundred gibbon skeletons and his report contains the following interesting observation: "Separate suprasternal ossicles occur in two of the gibbons examined (= 0·07%). . . . These ossicles are quite common in Man. . . . Never before have they been observed in primates other than man". Cobb[2] found no evidence of suprasternal ossicles in the skeletons of sixty-one gorillas, thirty-eight chimpanzees and eight orangs. Schultz has not seen this primitive condition "among many hundreds of monkey and ape skeletons examined, except in the two gibbons mentioned".

In view of these statements, it is of interest to record that I have found the condition unilaterally, in one chimpanzee, and, bilaterally, in one gorilla out of a total of 101 chimpanzee and 110 gorilla specimens examined. Radiographs of (*a*) the entire chimpanzee sternum and (*b*) the manubrium of the gorilla sternum are shown in Fig. 1. In each case the ossicles were situated towards the posterior margin of the upper border of the manubrium as is always the case in man.

The significance of suprasternal ossicles is still a matter for speculation. The first record of their appearance in man occurs in a paper by Béclard[3], but their discovery was claimed by Breschet[4]. Béclard considered the ossicles to represent rudiments of the furcular clavicle of birds; Breschet believed them to be atavistic remnants of the ventral ends of cervical ribs; Gegenbaur[5], Ruge[6] and Eggeling[7] were of the opinion that they were derived from the



(a) (b)

Fig. 1. Suprasternal ossicles are indicated by arrows: (a) specimen from a juvenile female chimpanzee; (b) specimen from an adult male gorilla

primitive episternum; Rambaud and Renault[8], Götte[9] and Dawson[10] derived them from the clavicle; Carwardine[11] from the precoracoid; Anthony[12] regarded them as sesamoids. Finally, after an extensive study, Cobb[2] expresses the view that the suprasternal ossicles are rudiments of the epicoracoids of the primitive shoulder girdle.

The specimens concerned are in the Birchington Collection of anthropoid skeletons. I am indebted to Prof. S. Zuckerman for permission to study this material.

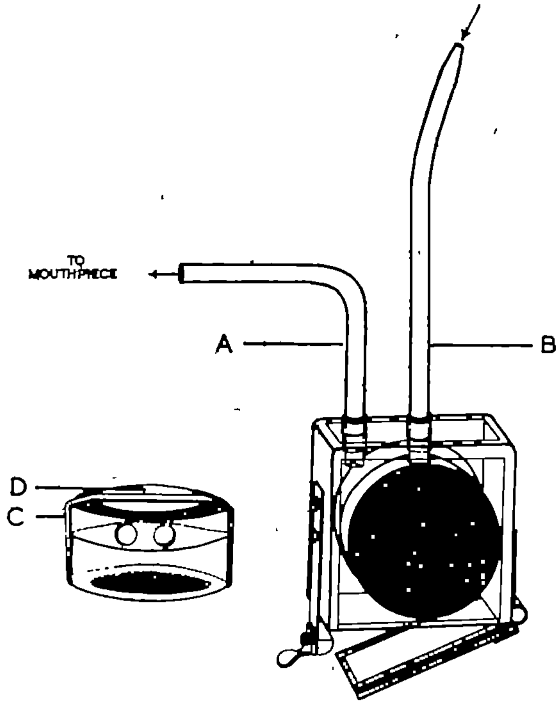
## A Combined Aspirator and Feeding Cage for the Collection and Testing of Insects as Vectors of Plant Viruses

This apparatus (Fig. 1b) has been designed to minimize the handling of insects during their collection and transfer from plant to plant in virus-transmission tests. It combines the principles of Kunkel's[1] aspirator for the collection of insects and Maramorosch's[2] leaf-feeding cage, so that insects can be sucked direct into the feeding cages.

The aspirator consists of a 'Perspex' box 2¼ in. × 2¼ in. × 2¼ in. with side walls ⅛ in. thick, and base and top ¼ in. thick. Joints are cemented with chloroform. The hinged base has an ⅛-in. flange, fitted with a 'Sorbo' rubber seal which is air-tight when closed by the spring clip. Two ¼-in. glass tubes are fitted in the top, using rubber sleeves to make an airtight union. One tube (*A*), projecting slightly into the box, is bent at right angles and connected by rubber tubing to a mouthpiece. The second or inlet tube (*B*) projects 2 in. into the box and is drawn into an ⅛-in. jet at the outer end.



(a) (b)

Fig. 1. (a) Insect-vector cage. (b) Combined aspirator and insect-vector cage

The cage (Fig. 1a) is made from a commercially manufactured polystyrene pill-box, 2 in. × 1 in., with a tight-fitting lid. Holes 1¼ in. in diameter are cut in the lid and base of the box and covered with 34-mesh nylon gauze, which is cemented in position with a solution of the plastic in chloroform. Matching ¼-in. holes are cut in the sides of the box and the lid. On the opposite side of the box a small hole is made through which a string-wick is fitted (not shown in Figs. 1a or 1b).

The cage is inserted in the aspirator so that the intake tube passes through the matching holes in the lid and side of the cage. Insects are drawn through the jet and into the cage by sucking air through the aspirator. The cage is then withdrawn, the inlet hole closed by twisting the lid, and another cage inserted.

In feeding tests, the cage is clipped on to the leaf with a 2-in. × ¼-in. rubber band (*C*). The disks (*D*), which were cut from the pill-boxes, can be used to press the surface against the nylon gauze through which the insects feed. The cage is orientated so that the string-wick is at the lowest point, and absorbs the honey-dew.

When several species of insects have been collected into one cage, they can be separated most conveniently by replacing the cage in the aspirator and anaesthetizing the insects with carbon dioxide passed in through the inlet tube.

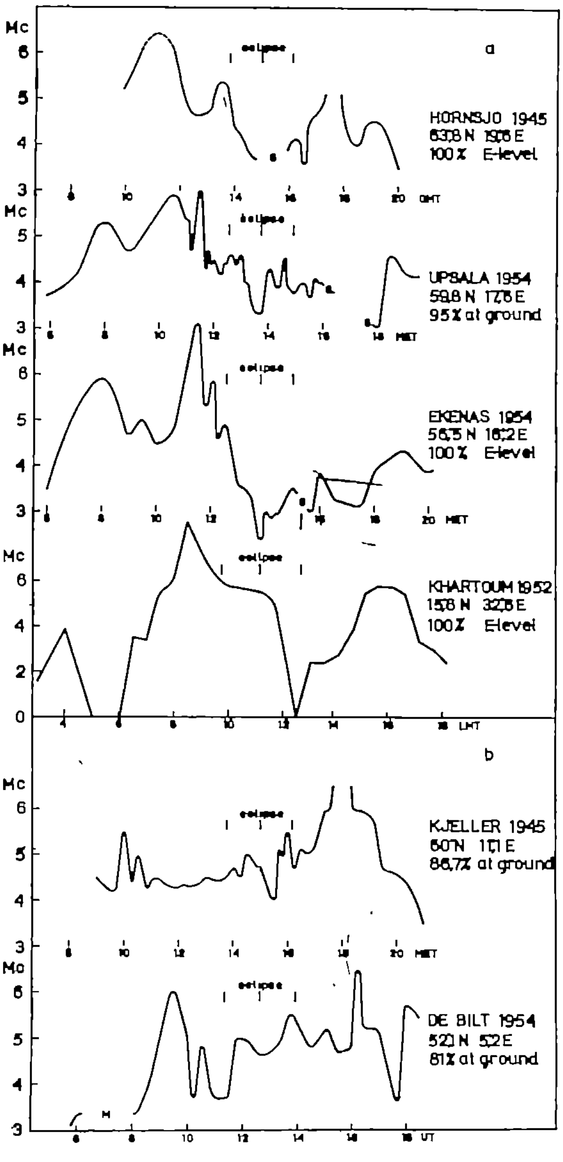
## Variation of *fEs* during Solar Eclipses

In a recent paper[1] Minnis has discussed the observed values of the *Es* layer during the total solar eclipse at Khartoum in 1952. He is of opinion that there is no obvious reason for attributing the observed decrease in *fEs* to an eclipse effect. It is known that a number of observers of other eclipses have not found any typical variations of *fEs*.

During the total eclipse on July 9, 1945, a typical variation of *fEs* was noticed[2], consisting of an increase some four hours before, with following decrease and total disappearance during the eclipse. The *Es* was of the special type present only in summer-time.

Particular attention was paid to the variation of *fEs* during the total eclipse on June 30, 1954, at Upsala and Ekenas, both stations operated by the Upsala Ionosphere Observatory. At both places the same typical variation was found. Fig. *a* shows the variation of *fEs* together with the observed values from Khartoum, 1952[1]. Fig. *b* shows the variation of *fEs* at places where the eclipse was somewhat less than 100 per cent.



The origin of the different types of *Es* is not definitely made clear. A comparison with observations from other stations requires great care because of the limitations in accuracy of the measurements. The median values of *fEs* from a great number of ionosphere observatories show, however, that the effect of the radiation from the sun is one of the agents producing *Es*. This is evident from the diurnal and seasonal variations of *fEs*. The decrease of *fEs* simultaneously with the course of the eclipse thus seems quite reasonable. The decrease of *fEs* is only found at places where the eclipse is total or nearly total. It seems that no eclipse variations are found at places with less than about 75 per cent obscuration.

The increase of *fEs* some hours before the moon's shadow strikes the earth cannot be due to any direct eclipse effect. Yet it seems that the typical eclipse configuration of sun–moon–earth is responsible in some manner for producing this effect.

## Dielectric Strength of Organic Liquids

Work in this laboratory on the conductivity of hexane at high steady fields has shown that measurements can be made at field-strengths far in excess of those previously reported. For gaps of 25 and 150 microns, it was possible to measure the conductivity up to stresses of 1,500 kV./cm. and 1,150 kV./cm. respectively.

This can be achieved by eliminating the pulses occurring at high fields which prevent current measurements. Spectroscopically pure hexane was used, and it was further dried and slowly distilled in a closed system under a reduced pressure to obtain a moisture- and dust-free liquid. The electrodes were polished so that no scratches were visible when they were viewed under an optical microscope, and they were finally cleaned with hexane. Even with this treatment, some current pulses occurred, and it was essential to keep these to a small amplitude because of the ensuing deterioration of the electrodes and the liquid and to reduce the risk of a spurious breakdown.

By keeping the applied voltage only slightly in excess of the onset voltage of the pulses, it was possible to control and eliminate them by a conditioning process. For this purpose a high resistance was connected in series with the test cell and the test voltage was increased only after the pulses had subsided. To facilitate the observation of the pulses, a high-gain pulse amplifier together with a cathode-ray oscillograph was used. A high-speed electronic diverter (operating time $\simeq$ 0·7 μsec.) safeguarded the electrometer and prevented spurious breakdown damage during conditioning.

As a rule, numerous pulses of appreciable magnitude were observed in a field region of 300–400 kV./cm., but beyond this the pulses were small except near the breakdown field, where very severe isolated pulses were likely to occur. Very pure liquids were relatively easy to condition, and a liquid showing no detectable pulses at high fields could be obtained; but for less pure liquids it was not often possible to reach the higher fields. The immediate breakdown region was indicated by the rapid rise in the steady current and by the further isolated current pulses which began to occur. In practice, the liquid was conditioned up to 100 kV./cm. or so beyond the maximum stress used during the measurements.

A series of conductivity curves for several gap-distances in the range 300–50 μ have been obtained. These tests show that:

(i) Once conditioning has been carried out for one polarity, no further conditioning is necessary for measurements of the other polarity.

(ii) For symmetrical electrodes with a spacing of about 75 μ there is no polarity effect, and identical conductivity graphs were obtained for stresses up to 1,150 kV./cm.

(iii) For electrodes of different metals, the conductivity curve depends on the nature of the cathode; for example, using chromium and silver for the electrodes, the current for 1,000 kV./cm. was 2½ times greater when silver was the cathode.

(iv) With proper conditioning the consistency of the results was very noticeable, provided the test electrodes remained in the closed system during the tests. In a long test the initial curves could be reproduced at the end of the test; but the purity conditions appeared to be so exacting that slightly different curves were obtained after a rest period of 12 hr.

The impression has been gained that the conductivity may be largely determined by adsorbed layers on the electrodes and hence depends upon the state of purity of the liquid; the two would be expected to be related, and a dynamical equilibrium would be established between them.

It is intended to publish a more detailed account of this work elsewhere.

## A New Thermal Method for Sound Absorption in Liquids

AFTER establishing[1] the equivalence of sonic and thermal energies (given by the relation $I = JH$, where $I$ is the intensity of sound at the source, $H$ is the heat produced by absorption of this sound and $J$ the conversion factor which has the same value of $4{\cdot}19 \times 10^7$ ergs/sec. as the mechanical equivalent of heat) this relationship was utilized in this Laboratory to develop a novel technique for the measurement of ultrasonic absorption coefficient in liquids. It consists of the measurement of heat produced at different points along the path of an ultrasonic beam, and its application in the formula $H = H_0 \exp(-2\alpha x)$ where $I$ in the usual formula for attenuation is replaced by $H$ because of the earlier equivalence relation. A series of measurements of absorption coefficient have been taken with this technique and the results have already been reported[2] elsewhere along with full experimental details. These results have shown that the accuracy of this method is high and the values of absorption coefficient so obtained are in close agreement with those obtained by other methods of measurement.

Recently, Dutta and Samal[3] have reported in *Nature* measurements of absorption coefficients using the same principle. According to them, the absorption coefficients of benzene and carbon disulphide are $75 \times 10^{-17}$ cm.$^{-1}$ sec.$^2$ and $115 \times 10^{-17}$ cm.$^{-1}$ sec.$^2$ respectively, as against the values obtained by others which are about $800 \times 10^{-17}$ cm.$^{-1}$ sec.$^2$ and $7,500 \times 10^{-17}$ cm.$^{-1}$ sec.$^2$.

Table 1

| No. | Liquid | Observed $\alpha/\nu^2 \times 10^{17}$ cm.$^{-1}$ sec.$^2$ at 28° C. | Previous results $\alpha/\nu^2 \times 10^{17}$ cm.$^{-1}$ sec.$^2$ | References |
|---|---|---|---|---|
| | 1 | 2 | 3 | 4 |
| 1 | Benzene | 816 | 900 at 20°–25°<br>906 ,, 30°<br>812 ,, 30° | 4<br>5<br>2 |
| 2 | *m*-Xylene | 89 | 80 ,, 27°<br>76 ,, 30° | 6 and 7<br>5 |
| 3 | *n*-Propyl alcohol | 84 | 77 ,, 26°<br>75 ,, 22°–38° | 8<br>9 |
| 4 | *n*-Propyl acetate | 138 | 145 ,, 30° | 5 |

To check on these results we have repeated our experiments at about 5 Mc./sec., utilizing our thermal technique. The results obtained are given in column 3 of Table 1. For comparison, results of earlier measurements are given in column 4. It may be seen from these values that the reproducibility is good.

It may also be noted that these results compare well with values obtained by other methods in this Laboratory, as well as with the commonly accepted values based on the results obtained by other workers using a variety of refined techniques[4–9]. Our thermal technique has also been used by Grossetti[10], who reports good results in water. For our experiments by this technique we have used a generator capable of delivering 10 watts radio-frequency power but set to a low output to prevent the crystal from giving rise to violent ripples in the liquid. It has been observed that, with correct matching, only a small amount of electrical power is needed for the work. Again, the sound energy is completely absorbed in the cell containing a long column of highly absorbing liquid and no correction is required to be made for sound energy leaving the system. This feature also gives rise to more heat, with the result that the accuracy of measurement is comparatively high in this method.

As against this, the results obtained by Dutta and Samal are in complete disagreement with those obtained by us by the above technique and confirmed by us here, as also with other results by workers using different methods. The deviation is obviously due to some flaws in the method and in interpretation of observations. A detailed paper on this work will be published elsewhere.

# FORTHCOMING EVENTS

## Wednesday, September 28

Physical Society, Colour Group (in the Small Physics Theatre, Imperial College, Imperial Institute Road, London, S.W.7), at 3.30 p.m.—Prof. W. D. Wright: "A Report on International Discussions on Colour, 1955: The C.I.E. Meeting, Zurich; the Colour Congress, Heidelberg; the F.A.T.I.P.E.C. Congress, Spa".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. G. I. Hitchcox: "Extending the Limits of Resistance Measurement Using Electronic Techniques".

## Wednesday, September 28—Friday, September 30

National Smoke Abatement Society (in the Grand Hall, Town Hall, Bournemouth)—Twenty-second Annual Conference.

## Thursday, September 29—Friday, September 30

Institute of Physics, Stress Analysis Group (at Stephenson Hall, The University, Sheffield)—Ninth Annual Conference.

## Saturday, October 1

Association of Clinical Biochemists (joint meeting with the Association of Clinical Pathologists at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2), at 9.30 a.m.—Scientific Papers.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chemists (with a first- or second-class honours degree and preferably with some postgraduate research experience), at the North Thames Gas Board, Chemical By-Products Works, Beckton, East Ham, London, E.6, for research on problems in connexion with coal tar distillation, and the manufacture of phenols, naphthalene and bases—The Staff Controller, North Thames Gas Board, 30 Kensington Church Street, London, W.8, quoting 666/288 (September 30).

Curator (with a university degree in engineering and/or naval architecture or equivalent qualification) of Shipbuilding and Engineering—Town Clerk, City Chambers, Glasgow (September 30).

Lecturer or Assistant Lecturer in General and Physical Chemistry—The Dean, Guy's Hospital Medical School, London Bridge, London, S.E.1 (September 30).

Physical Chemists (with good honours degree), for work covering both fundamental and applied research on coal—National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting 88/68 (October 5).

Scientific Officer (with first- or second-class honours degree in physics, mechanical or chemical engineering or equivalent qualification) at the Ministry of Supply Research and Development Establishment, Waltham Abbey, to assist in research on heat transfer phenomena at high temperatures—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.329/5A (October 8).

Assistant Mathematical Statistician (with a degree in statistics or science or mathematics which has included a statistics course), to assist in the design and analysis of laboratory and small-scale plant experiments—National Coal Board, Central Research Establishment, Stoke Orchard, near Cheltenham, Glos, quoting 88/70 (October 12).

Chair of Physical Chemistry at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 12).

Chair of Physics at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 18).

Chair of Geology at Bedford College—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 24).

Assistant Lecturer or Lecturer (with a degree in agriculture or science) in Entomology, at Canterbury Agricultural College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Chair of Education at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Chair of Medicine at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Chair of Surgery at the University of Sydney—Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31)

Lecturer or Senior Lecturer in Dental Biochemistry at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Senior Lecturer or Lecturer (preferably with experience in the design and construction of hydraulic works and apparatus) in Civil Engineering at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Senior Lecturer in the Department of Metallurgy and Assaying at the University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, October 31).

Assistant Lecturer in the Department of Economics—The Registrar, The University, Liverpool (November 1).

Biochemist (with experience in the chemistry of proteins), for a laboratory engaged in work on human plasma—Secretary, Lister Institute of Preventive Medicine, Elstree, Herts.

Fuel Technologist (graduate in fuel technology, chemical or mechanical engineering, physics or chemistry, and preferably with experience of high temperature furnaces) in the Fuel Technology Section, to work on problems involving fuel utilization and heat transfer in the iron and steel industry—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1 quoting F.T.1.

Lecturers (3) (with a degree in engineering or science, lecturing experience and specialist knowledge of either electrical engineering electronics or servo-mechanisms) at the R.E.M.E. Training Centre Arborfield—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting D.422/5A.

Microbiologist (with first- or second-class honours degree and at least three years postgraduate research experience in bacteriology or allied fields), for basic research on taxonomy and biochemistry of marine bacteria—The Superintendent, Torry Research Station Aberdeen.

Physicists and Electrical Engineers, Scientific Officer or Experimental Officer grades (with first- or second-class honours degree or H.S.C. (science) or equivalent qualifications) at the Armament Research and Development Establishment, near Sevenoaks, Kent for research and development work on weapon systems and in particular fuse techniques, also experimental design, development and operation of physical measuring apparatus—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.335/5A.

Pleistocene Geologist (with first- or second-class honours degree in geology and postgraduate experience in sedimentary geology of the Tertiary and Quaternary formations, and special interest in geomorphology and stone age cultures) in the Geological Survey Department, Uganda, to undertake field mapping with special reference to the Plio-Pleistocene rocks of Uganda, including lacustrine and alluvial deposits and their associated physiographical features—Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.105/9/05.

Production Chemists (with honours degree in chemistry or chemical engineering or A.R.I.C. or A.M.I.Chem.E. or equivalent qualifications), for Royal Ordnance Factories in South-West Scotland, Pembrokeshire and Somerset, to assist in technical control or administration for explosives and acids manufacture, including development work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.696/5A.

Scientific Officer (with first- or second-class honours degree in mechanical engineering, physics or chemistry or equivalent qualification) at the Ministry of Supply Chemical Defence Experimental Establishment, Porton, to apply results of research to development of personal and collective defensive equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.336/5A.

Senior Experimental Officer (with at least H.S.C. (science) or equivalent; a degree in physics or electrical engineering an advantage) in the General Physics Division, to carry out research and development work in the field of high speed frame and streak photography—Establishment Officer, United Kingdom Atomic Energy Authority, A.E.R.E., Harwell, Didcot, Berks, quoting 2/103/395.

# UNIVERSITY AUTONOMY IN SOUTH AFRICA

THE Hoernlé Memorial Lecture on "Education and Race Relations in South Africa"* given by Dr. T. B. Davie, principal and vice-chancellor of the University of Cape Town, one of the four universities of the Union which thus far has held to the ideals of British universities in respect of policies of the open door and complete academic freedom, is an important and scholarly discussion of the interaction of educational policies and race relations in South Africa. Those strained and worsening relations, as Dr. Davie notes, in the present world situation are far from being a matter of purely domestic concern to the Union of South Africa, and for that reason alone the publication of this lecture would be welcomed as a contribution to the clear understanding of a problem of international import. Still more, however, is this lecture to be welcomed as a contribution to clear thinking on the issues of academic freedom in the modern world, and the place of the university in a modern community, whether multiracial or not.

Dr. Davie starts by proclaiming the conception of the functions and ideals of a university as understood by the Western democracies. That concept, he argues, is essentially of a community dedicated to the pursuit, preservation and dissemination of learning for its own sake, open to all who can benefit by or contribute to its teaching or work, and demanding of them absolute intellectual integrity, prizing scholarship and research as the major requirements of those who work within its walls, and demanding the fullest possible measure of academic freedom as the condition for fruitful creative work. Nevertheless, the modern university is not divorced from the realities of the modern State, from which in increasing measure it derives its financial support, and in return the university provides much of the theoretical and technological training for the professions and the higher levels of the public service.

Attention is directed to the potential clash between this responsibility for service to the State and the responsibility for unprejudiced, untrammelled search for the truth; though, as Dr. Davie emphasizes, the two functions are not necessarily inconsistent or opposed. Danger arises if, in practice, service to the State comes to mean service to the ideology of a particular section in political power at that moment. Where universities have taken training for service to the State as their primary function, discriminations against staff and students on ideological grounds and perversions of the truth in the content of their teaching are liable to occur, and may develop into indoctrination.

Reviewing the position in relation to the State of the nine institutions which, with the University College of Fort Hare, rank as universities in the Union of South Africa, Dr. Davie points out that English-medium and Afrikaans-medium universities differ also in racial origin, in religion, in political background, and in their degree of urbanization, the latter drawing a larger proportion of students from farms, villages and small towns, while most of them are also adherents of the Calvinistic protestantism of the Dutch Reformed Churches. Moreover, the use of Afrikaans as the medium of instruction restricts the supply of lecturers and increases the risk of inbreeding. In these universities, from which non-Europeans are rigidly and completely excluded, the requirements in respect of staff and students attached to their concept of academic freedom thus came to differ from those of the English-medium universities. While this may be an expression of university autonomy, that it should be linked with a party-political and publicly announced government policy points to a different scale of values. Dr. Davie does not enter further into this question of racial discrimination in the universities, beyond indicating the strength with which the idea that there should be no such racial discrimination in the academic field is held by at least two of the English-medium universities, both in the interests of the universities themselves and of the country. Apart from this, it should be remembered that strong protests have already been made outside the universities against the projected extension of racial segregation in the South African universities, and a commission which reported on the situation to the Fifth International Student Conference at Birmingham last July urged that at least the remaining unsegregated universities should continue to be multi-racial, and could find no reason why any South African university should discriminate between races in the admission of students or segregate students once admitted to a university.

In a statement issued last year, it was argued that the existence of the two open universities has enhanced South Africa's reputation overseas and afforded concrete expression to the desire for goodwill between Europeans and non-Europeans. The report made to the International Student Conference referred explicitly to the influence which foreign public opinion often exercises on the policy of the South African Government, and suggested that responsible representations from overseas, given effective publicity, could assist in preventing further encroachment on the autonomy of the South African universities. Dr. Davie makes it clear that there is a division in this matter among the students themselves, but that there is strong student support for the open university; and one of the merits of his lecture is the plain warning he gives of the serious consequences likely to follow from the Government policy, in view of the cultural and political divisions which are the counterpart of educational deficiencies in the Union. First he points out that the Government's apparent intention to enforce uniformity of policy on all the universities involves risks of psychological damage to the Government party itself. Next, it undermines the concept of a South Africa large enough to embrace elements of both African and European descent. Thirdly, it threatens to determine the future education of the coloured and native elements in a way likely to provoke embitterment and opposition among those of non-European origin.

---

* "Education and Race Relations in South Africa." By Dr. T. B. Davie. (Eleventh Hoernlé Memorial Lecture.) Pp. iii+31. (Johannesburg: South African Institute of Race Relations, 1955.)

Dr. Davie is concerned more particularly to note the way African education generally is likely to be affected if all leaders of the community are trained in universities in which the primary objective is training for service to the State. Inevitably, educational policy and practice at all levels will be directed to the same objective rather than to the development of the child to the full extent of its capabilities. Ignoring the political and religious aspects of the policy represented by the Bantu Education Act of 1953, Dr. Davie points out that, while the Act will double the number of children to be admitted to the schools, the restricted daily amount of teaching need not be seriously retrogressive if the child can be induced to remain at school for a longer period. He is more concerned, however, as to the effect of insistence on using the mother tongue as a medium of instruction, coupled with the teaching of the elements of both English and Afrikaans; and that the obvious intention of the Act is that education of the African child shall be different from that of the Afrikander, and establish and perpetuate an inferior status for the former. This is bound to affect the type of education provided in the upper standards of the primary school, as well as the curriculum of the high school; and it is likely also to diminish the chances of fostering the eager zest for knowledge which is the hallmark of the true candidate for university education. Most of the aspirations of the potential scholar will be suppressed, and a sense of bitter frustration produced in those who do succeed in entering the universities.

This depressing educational outlook for the non-European in South Africa is presented by Dr. Davie quite objectively; but he points out unequivocally that if Government policy specifically limits non-European education to fitting the pupil for a place in society inferior in social and political status to that of the Afrikander, there can be no place for him in universities to which the latter are admitted without creating discord and dissension within the universities to an extent incompatible with good work. To encourage, however, an academic education similar to that of the Afrikander might well result in an increase in the number of those of non-European origin seeking and meriting admission to the Universities of Cape Town and the Witwatersrand, for example, which would demand action on an extensive scale. He does not believe that the present friendly relations between students of all races in those universities would be endangered if the proportion of non-white to white students approached equality, though new universities located in certain areas might also be required; and he suggests that the establishment of new institutions of a type similar to the 'junior college' of the United States, for two-year courses of higher or post-matriculation education and working in conjunction with an established university, might meet a real need of all classes of the population.

Dr. Davie is clearly concerned that the South African universities may soon be faced with additional demands far beyond their capacity without considerable expansion. He points out that in this connexion it is important to consider the severely limited openings for the educated African which at present exist, and the detrimental effect of this position both on race relations and on the curricula of the university itself. Although, however, tension is steadily rising between non-European and European, and the relation between British and Afrikaans sections of the population is also steadily and rapidly deteriorating, there is little that the universities can do to promote rapprochement. Dr. Davie seeks rather a solution at the other end of the scale: in the infant school, not in the universities. The separation of the English-speaking from the Afrikaans-speaking children in unilingual schools is, Dr. Davie believes, more than any other single factor, responsible for keeping alive the animosities and divergencies between the two sections. Mother-tongue instruction, while obviously desirable, is not necessarily the best in the interests of South Africa. With instruction both in the mother-tongue and in the official language, within one generation the high schools and universities would be fed by fully bilingual scholars; and its beneficial results would be manifested within five years, once politicians were determined to seek full co-operation between the two main sections of white South Africans.

While the universities can do little to relax the present tension between the two groups of Afrikander and English-speaking South Africans, Dr. Davie believes that the universities could make a tremendous difference by taking a stand against all measures of coercion in the educational field. They could do this in the knowledge that they would thereby implement the recognized policy of universities throughout the Western democracies. It is the high and solemn duty of all universities to inculcate in their students that toleration of ideas which characterizes the really educated man, and the ideal of rendering available the whole of knowledge to everyone who can benefit by it. In the measure with which they address themselves to that task, the universities of South Africa can count on the understanding and firm support of universities throughout the free world.

Dr. Davie addresses himself indeed primarily to a South African audience. His two specific requests, that each university be allowed to decide on and develop its own policy in relation to the admission and academic privileges of its students, European or non-European, and that, when planning for the further university needs of the socially and educationally awakened non-Europeans, the facilities provided should be additional and not alternative to those now available, are manifestly matters for South Africans alone. But like his dignified plea for toleration and for unbiased judgments, they breathe a spirit of integrity and impartiality which commands confidence. The Hoernlé Memorial lecture of 1955 is evidence that South Africa does not lack those capable of making a university an independent centre of informed and reasoned criticism and of constructive creative thought, and this in itself demonstrates the importance of university autonomy.

# VICTORY OVER THE PLAGUE

## Plague

By R. Pollitzer. (World Health Organization: Monograph Series, No. 22.) Pp. 698. (Geneva: World Health Organization; London: H.M. Stationery Office, 1954.) Cloth: 10 dollars; 65*s.*; 40 Swiss francs. Paper: 9 dollars; 60*s.*; 36 Swiss francs.

In the preface to this important work, Dr. R. Pollitzer says that the most recent publication in English which dealt comprehensively with plague was the treatise by himself in collaboration with Drs. Wu Lien-teh, J. W. H. Chun and C. Y. Wu which appeared in 1936. This book had long been out of date, and Dr. Pollitzer, the only surviving author, had been frequently asked to publish a revision. The advances in the control and treatment of plague made in the intervening years rendered it desirable to prepare an entirely new work. This Dr. Pollitzer did, and it was published serially in the *Bulletin of the World Health Organization* between 1951 and 1953. It is now republished in the form of a well-produced monograph. Incidentally, when Dr. Pollitzer was writing this preface, the book by another great authority, Dr. L. Fabian Hirst, entitled "The Conquest of Plague", had not appeared. It should be said that these two works do not compete with each other. Dr. Hirst's very stimulating and penetrating study is more in the nature of an extensive essay on epidemiology than a text-book.

At the present time, plague is confined largely to India, Burma, Thailand, certain areas of China, Java, Madagascar, and the equatorial belt of Africa. Cases occur also in Arizona and New Mexico, in South Africa, and in certain South American States, but these are 'sylvatic' or 'wild-rodent' plague. The disease has always shown the character of long-term periodicity, and the last great pandemic wave began in 1894. As this wave has not yet subsided, it is still too early to say whether the very marked reduction which has occurred in the incidence in recent years is a result partly of this natural decline or whether it has been caused or accelerated by the latest methods of control. Although intimate association with plague is at present confined to workers overseas, the complex epidemiology of the disease, and the fact that its absence from the European scene is due largely to effective anti-plague measures, make it desirable that there should be available a comprehensive and authoritative reference book on the subject. Dr. Pollitzer's book fulfils this purpose admirably.

In the fight against plague, great advances were made following the discovery of *Pasteurella pestis* in 1894, especially by the work of Simond, Ghon, Haffkine, and the Plague Commission under the late Sir Charles Martin. Although a typical concomitant —or rather antecedent—of a plague outbreak is an epizootic of the disease in rats, it is surprising that it took so long for this fact to produce practical results in the field of control. The association between disease in rats and in man is mentioned in some ancient writings, and it was noted in China in 1792, in 1834, and again in 1894, the year in which Yersin demonstrated the plague bacillus in dead rats. Yet in Hong Kong the destruction of rats was not begun until 1901, and the importance of the rat in carrying plague in ships was not recognized until 1906. The equally important role of the rat-flea in sporadic plague was first elucidated by Simond in 1897; yet the method of infection by regurgitation during attempted feeding was not shown until 1914. Since that date very extensive researches have been carried out on the fleas of the black rat, the sewer rat and other rodents, and Dr. Pollitzer's book contains a section of eighty pages on this subject. Despite suggestions which were made to the contrary not very long ago, the result of recent work has been to establish the vital importance of the genus *Xenopsylla* in spreading plague, and especially of *X. cheopis*. Dr. Pollitzer suggests that the role of the flea in spreading plague must be confined to comparatively short distances on land. Long-distance spread of plague through maritime traffic has nowadays almost ceased to occur; if it were due to fleas, it would have been found not infrequently, despite the universal measures practised for the extermination of rats.

It is perhaps not realized widely enough that, from the epidemiological and clinical aspects, bubonic and primary pneumonic plague are virtually distinct diseases. It has been shown that pneumonic plague is not due to any peculiar characteristic of the organism, or to a mixed infection. Various hypotheses have been advanced to explain the fact that certain patients develop plague pneumonia; of these, possibly the most important is the theory that patients who travel during the early stages are liable to detach thrombi which give rise to pulmonary emboli, and the theory that vitamin deficiency is specially liable to accelerate pneumonic complications, as in the Black Death. The most significant feature is that plague due to wild rodents is nearly always pneumonic. Before the advent of the new drugs, patients suffering from pneumonic plague almost invariably died within two days from the onset. Fortunately, the disease is relatively easy to control by the methods applicable to any droplet-borne infection; but there is in some areas a drawback in that the relatives of the patient object to his being taken to hospital and to their own enforced segregation.

There are two aspects of the plague problem to-day which are worthy of the widest notice. The first is the fact that even in Britain unobtrusive changes have been taking place in the prevailing rat species. *Rattus rattus*, the black rat, was supposed to have been brought to Europe by returning Crusaders in the twelfth century, though, as MacArthur, Hirst and others have pointed out, there is evidence that this species was known in Europe from much earlier times, and the Romans may have known both it and the sewer rat. Whatever may be the truth about the early history, there is no doubt that in 1727 there occurred a westward migration of the sewer rat, *R. norvegicus*, from the shores of the Caspian Sea. From that period the black rat fought a losing battle, and by the beginning of the present century it was supposed to be extinct in Great Britain. But since 1911 *R. rattus* has again been present in London, and by 1937 it formed 90 per cent of all rats found in the London area. Conditions during the Second World War were again favourable to *R. norvegicus*, but it appears that the black rat is once again winning the battle. Hence, should the other factors necessary for a localized plague outbreak appear again in Britain, the organism would have no difficulty in finding suitable animal hosts.

The other aspect which deserves mention is the fact that the plague bacillus finds a biologically congenial habitat in the wild rodents of the great open spaces of the world, and that from them the disease is constantly being spread to man. In 1856 Tcherkasoff mentioned in his "Memoirs of a Hunter in Siberia" that the natives of Transbaikalia on the Asiatic plateau were aware of an infectious disease of the local marmots (tarabagans) which spread to man, but which they were able to avoid by not catching or eating sick tarabagans. In 1910 large crowds of inexperienced Chinese invaded these breeding grounds of the tarabagans, since at that time the price for skins was high. They snared both healthy and sick animals, and the result was the great Manchurian epidemic of pneumonic plague which cost sixty thousand lives. Since then, ground rodents in many countries have been incriminated as normal hosts of the plague bacillus. The resulting plague outbreaks in man were until recently labelled 'sylvatic'. But Pollitzer thinks that the term is ambiguous and calls the condition 'wild rodent' plague. Hirst has coined the word 'campestral'. There are fundamental differences between rat-borne and campestral plague. The former leads to collective cases in human settlements, and the numbers of persons affected may be very large. Campestral plague, on the other hand, results only in sporadic cases among those who have penetrated to the haunts of the rodents. Against this must be set the fact that, in numbers and in the areas involved, the extent of campestral infection is very great; against it also must be set the high case-mortality of this type of plague.

Despite the great difficulties, efficient control measures have generally kept plague away from Western Europe during most of this century, and in recent years a great weapon has been made available in DDT. In the sphere of therapy, enormous advances have been effected. A text-book of medicine of 1941, which I picked off my shelf at random, states that treatment is symptomatic, as no specific is known. By 1953 streptomycin and the sulphonamides had revolutionized treatment and had almost permitted us to speak of plague in all its forms as a mild disease.

Dr. Pollitzer is to be heartily congratulated on the completion of this great work. As a students' text-book it will find its place immediately, and as a work of reference it will be consulted for many years.

E. Ashworth Underwood

# A NEW INTRODUCTION TO NEWTON

## Sir Isaac Newton

By Prof. E. N. da C. Andrade. (Brief Lives Series.) Pp. 140. (London: William Collins, Sons and Co., Ltd., 1954.) 7s. 6d. net.

IN 1950 the firm of Max Parrish and Co. published in its series of "Personal Portraits" an "Isaac Newton" by Prof. E. N. da C. Andrade (reviewed in *Nature*, 166, 1046; 1950). Prof. Andrade's latest study of Newton is not a revised edition of this earlier book, but is an entirely new work for another publisher, specially written for a series of "Brief Lives" which includes, among others, Queen Victoria, Elizabeth I, Drake and Wren. In writing the first book, Prof. Andrade had the young reader particularly in mind, his aim being to set down what he himself when young would have liked to know about Newton; this second book also has been kept as simple as possible, so that it may be suitable for young as well as older readers. It is not surprising, therefore, that the two books, of approximately the same length, written by the same author and addressed largely to the same public, should be very similar in scope and treatment. The texts, however, are nowhere identical.

Prof. Andrade's main object is to make clear what it was that Newton did and why it was of such importance for the development of scientific thought (p. 11). To this end he begins by reviewing the state of science at the time of Newton's birth: the influence of Aristotle on men's attitude to scientific inquiry, the survival of the Aristotelian idea of natural and non-natural motion, the accepted view that white light was simple, colour a complication. In view of the important part played by astronomy, in particular the motion of the planets, in Newton's work, Prof. Andrade outlines the history of that subject up to Newton's time: the Ptolemaic and Copernican systems, Kepler's Laws, Descartes's theory of vortices.

Turning next to Newton himself, Prof. Andrade shows him first as a boy of no particular genius but with a marked bent for handicrafts; and then as an undergraduate at Cambridge, where only Barrow saw in him something quite out of the ordinary. The crucial period spent at home at Woolsthorpe during the plague years, "perhaps the most fruitful years of his life" (p. 40), form the subject of the next chapter (Chapter 3). It was during this time that Newton, intellectually alone, made his fundamental discoveries concerning the moon's motion and the composition of white light, invented the method of fluxions, and, as Prof. Andrade considers almost certain, arrived at his 'laws of motion'.

Newton returned to Cambridge early in 1667; in October 1669, at the age of twenty-six, he succeeded Barrow as Lucasian professor of mathematics. At this time his great interest lay in optics, and his early work in this field, including the construction of the reflecting telescope, is described in Chapter 4. Then follows an account of the events which led to the publication in 1687 of the "Principia", sufficient being said of the contents of this great work to bring home the magnitude of Newton's achievement.

The prodigious feat involved in producing the "Principia" in the space of eighteen months, took its toll of Newton's health and led to a period of acute mental depression. Prof. Andrade deals very understandingly with this period, rejecting the suggestion sometimes put forward that it was a period of madness from which Newton never completely recovered; the "silly story" of the dog Diamond is dismissed as quite out of keeping with the facts.

Newton had recovered by 1693; in 1696 he went to London as Warden of the Mint, and the important work which he did here in connexion with the reform of the coinage, as well as his continued scientific activities, affords ample evidence that his mental powers had suffered no permanent setback. In discussing the "Opticks", Prof. Andrade points out (p. 108) that, though all the work was probably done before Newton went to London, the added "Queries" in the second edition (1717) not only show the profound thought given, since the publication of the first edition in 1704, to the matters with which they deal, but also contain some of Newton's most inspired suggestions. Prof. Andrade concludes his account of Newton with a chapter on "Newton the Man", an unbiased assessment of his character.

Apart from a few obvious misprints, there are only two points which call for correction. The statement of Kepler's third law (p. 30) was probably intended to read: "the cube *of the mean radius* of the orbit". The text on p. 136 does not tally with the accompanying figure illustrating the retrograde motion of the planets: to conform with the figure, line 3 should read "between *d* and *e*" and line 6 "from backwards to forwards" (or alternatively broken arrows should be shown between *b* and *c*).

This masterly introduction to Newton will be welcomed by all interested in the history of science, not only as a penetrating study of Newton himself, but also for the insight it affords into many matters affecting Newton's life and work.

N. H. DE V. HEATHCOTE

## EARTHQUAKE GEOGRAPHY

### Seismicity of the Earth and Associated Phenomena

By B. Gutenberg and C. F. Richter. Second edition. Pp. x+310. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1954.) 80*s*. net.

THIS work on earthquake geography by two well-known seismologists, Prof. B. Gutenberg and Prof. C. F. Richter, now working in Pasadena, may be considered to be the modern counterpart of the work of such giants of the past as Count R. de Montessus de Ballore and Dr. C. Davison, and is an extremely important work.

In a young and vigorous subject, such as this relatively is, in which the recording apparatus and hypotheses are changing and in which the data are accumulating so rapidly, it is indeed a pleasure to note that a second edition of this book is required so soon. This contingency has enabled the authors to bring the work up to date to the end of 1952, and in order to save additional printing costs this has been done in a manner so as to cause as little disturbance as possible to the original printing. With regard to the tables numbered 14, 15, 16, which are lists of earthquakes arranged according to depth of focus and location, these have been extended chronologically, and it must be remembered that they are selective within the limits set by the authors. Profs. Gutenberg and Richter do not intend them to supplant the more complete records of the International Seismological Summary, the authors of which are now working on the 1946–47 reductions. Tables 4 (largest earthquakes) and 6 (annual energy release in earthquakes in ergs), being small, have been brought up to date and rearranged where necessary without difficulty. Tables 17, 18 and 19 (regional lists) have had their additions put at the end, and references to new literature have been added. Where major additions have been required, these have been collected together, beginning on p. 104.

Better seismographs such as those constructed recently by Prof. W. Hiller, of Stuttgart, and better timekeeping (now in many seismological observatories measured correct to 0·1 sec.) have given better data, and hence it is now possible to determine the velocities of seismic waves at various depths in the earth with greatly increased accuracy. Moreover, data from new stations such as those at Kiruna (north Sweden), Tamanrasset (West Africa) and Lwiro (Belgian Congo) assist in the elucidation of local deep structure. Lateral and vertical variations in earth structure are not confined to the difference between continents and oceans and to mountainous regions. In this connexion, explosion seismology has been increasingly used in attempts to solve academic problems concerning earth structure, as well as in the search for minerals.

Though not always found at exactly the same depth, the Mohorovičić discontinuity (p. 26, etc.) has been found to be present under all continents and under the Atlantic and Indian Oceans (depth 37 km. under the Canadian Shield and 45 km. under Japan). The velocities of primary waves above it approximate to 6·5 km./sec. and those below it to 8 km./sec. The generalized word for the layer immediately under the sedimentary rocks, namely the "granitic layer", is gradually being discontinued for various reasons, and in this new edition has been replaced to some extent.

Prof. Gutenberg believes that above the Mohorovičić discontinuity there exists at least one layer having low wave velocity and presumably relatively low strength. The consequences of this hypothesis and the comparison of these consequences with those of other hypotheses are still being considered.

The book is essential for students of geophysics, geology, geography, civil engineering and earthquake insurance, and its value has been enhanced in this new edition by the additions and amendments.

ERNEST TILLOTSON

## TEACHING OF M.K.S. UNITS

### The Teaching of Electricity, with special reference to the Use of M.K.S. Units

(A Report of a Sub-Committee of the Science Masters' Association.) Pp. xii+135. (London: John Murray (Publishers), Ltd., 1954.) 10*s*. 6*d*. net.

THE teaching of electricity is a matter of great importance to schools, technical institutions and universities, and this book on the subject, sponsored by the Science Masters' Association, is one which should be very carefully considered. It is really an attempt to present a case for the teaching and use in Britain of the rationalized M.K.S. system of units in schools, and it can be said at once that the committee of the Association charged with the task has done it well. Now, it is not the province of a reviewer to present an opposing point of view, although in passing he may mention that in his teaching and, still more in his researches, he has never found the traditional units to fail him; and he is of the opinion that the rush to popularize M.K.S. units in certain quarters is ill-conceived and likely to be of relatively short duration, except for those workers who are fundamentally interested in and continuously working in electromagnetic theory.

The book is divided into seven main parts: the recommendations of the committee, the syllabus intended for advanced and scholarship levels in the General Certificate Examination and notes thereon, definitions of units, theoretical proofs, experiments and, finally, two appendixes on experimental details and additional experiments which may be used to support the syllabus. They are all worthy of careful perusal. Some of the experiments are highly ingenious; for example, it is interesting to find a description of a form of the Lorenz rotating-disk method for the absolute determination of the ohm adapted for use in schools.

But, among the recommendations of the committee, one finds the omission of quantitative magnetism, "because we now know that an isolated pole is an impossibility and that a magnet with permanently disposed poles is an impossibility". So too is a permanent electric current. A sixth-form pupil is asked to accept without question $\epsilon_0 = 1/\mu_0 c^2$; but he may not be asked to imagine that a sheet of surface magnetism may be pictured as made up of free poles!

As a university teacher, the reviewer dreads to think of what is likely to happen if these recommendations are adopted in their entirety—no magnetism because of lack of imagination, and probably little or no electrostatics because some teachers consider that something must be left out and that the experiments never work anyway. Still, it is good to know that a knowledge of magnetism may be useful in the 'degaussing' of ships; perhaps their navigation is relatively unimportant !

But assuming that we are to cease to train physicists and that we are only interested in producing electronic engineers, may one commend the following suggestions which will enable some quantitative magnetism to be done. On p. 44 is given an expression for the field along the axis of a coil carrying a current. Let us now use two coils and so introduce the Helmholtz coil system. Let the Helmholtz system be mounted with its axis along the magnetic meridian (assuming that this is known), with a small vibration magnetometer mounted at the centre of the system. In this way, by passing known currents through the coils one ventures to hope that the idea of the magnetic moment of a small permanent magnet (high-coercivity 'Alcomax' can be obtained) and of the horizontal component of the earth's field may be gained. Now rotate the Helmholtz system through 90° about a vertical axis, leaving the vibration magnetometer fixed. On passing different currents through the Helmholtz system, one may obtain deflexions of the magnet (using a mirror attached to it for accuracy of measurement) and verify the usual tan θ relation. Next, replace the Helmholtz coils by a solenoid of small cross-section placed in the Gauss *A* position, and so obtain an idea of the $2Md/(d^2 - l^2)^2$ relation, where $M$ is given an appropriate value by passing a current through the solenoid. Now replace the solenoid by a permanent magnet and again verify a $2Md/(d^2 - l^2)^2$ relation. The way is now open for the use of short magnets in the traditional manner.

These are matters which the readers of this stimulating book will undoubtedly ponder upon, and they may conclude that the rationalized M.K.S. system of units is not necessarily bound up with the rejection of point electric charges and magnetic poles.

L. F. BATES

# AMERICAN CHEMICAL INDUSTRY

## American Chemical Industry

A History. By Williams Haynes. Volume 1: Background and Beginnings, 1608–1910. Pp. lxxvii + 512 + 32 plates. Volume 5: Decade of New Products, 1930–1939. Pp. li + 622 + 32 plates. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1954.) 112s. 6d. each vol.

THE appearance of these volumes completes the ambitious design which is set out with somewhat disarming modesty in the first volume, only now available. Vols. 2 and 3 appeared in 1946, Vol. 4 in 1948, and Vol. 6 (a history of 219 United States companies in the chemical and allied fields) in 1949. Vol. 5, now published, is logically the last volume and concludes with the outbreak of the Second World War in 1939, though there is sporadic mention of later developments (that is, in Vol. 6).

The work is mainly economic and political in bias, and there is no technical detail, though practically all technical advances are mentioned with adequate references, very often to review articles. The whole is obviously a reference work and scarcely for general reading, and the aspects of American industry with which it is mainly concerned are not of great interest in Britain, or indeed in any European country. The first volume is perhaps an exception, especially in the earlier chapters, where an excellent review of Colonial policy and Colonial history is concisely set forth with the always interesting beginnings of the early industries. This might repay study by other than science students, and indeed the appeal of all six volumes to the economist and historian might be considerable.

Perhaps the strength and weakness of the whole work is to be seen in the thirty-two pages of "Chemical Chronology" in Vol. 5, where it is most highly developed, set out in four columns—general; industrial–commercial; technical–scientific; and contemporary events—remembering that the work is founded primarily on Column 2, though with references to most of the items in Columns 1 and 3 and, in some cases, to Column 4. Thus on p. xx, under the year 1930, three of the ten items in Column 1 are: Hawley-Smooth Tariff in effect; Bureau of Industrial Alcohol, Treasury Department, separated from the Prohibition Bureau, Justice Department; and tri-*o*-cresyl phosphate found cause of bootleg Jamaica ginger paralysis. In Column 2 there are nine short items, such as methanol absolved as health hazard, one-third output in anti-freeze; tankcar shipment of anhydrous hydrofluoric acid; and Mallinckrodt opened Canadian factory; followed by a complete list of company mergers and, on the next page, a list of new companies and incorporations. In Column 3 there are eighteen items ranging from kojic acid from corn sugar, and cellulose acetate moulding powder introduced, to element 87 discovered, F. Allison and E. J. Murphy, and Armour Research Foundation opened; in this column, at the end of each year, is a list of medals and awards, not confined to the United States. Finally, in Column 4 there are seven items, including London naval reduction treaty; discovery of ninth planet, Pluto; international rayon conference; and tercentenary of first use of cinchona bark in malaria celebrated at Missouri Botanic Gardens. It should be said at once that the comprehensiveness and not the inconsequence of the items is what the reviewer has in mind. To see the work in a just perspective it might be well to imagine the fascination of a similar work on the British industry, with its concise biography of practically every founder, director and prominent research worker mentioned, though one could scarcely parallel the unfortunate "killed in a payroll holdup in 1933" (p. 246 *n*).

The list of errata included in Vol. 1 shows how few and unimportant these, in general, are, though in that volume itself, p. 248, "viscous" is printed for "vicious" with a rather contradictory effect. There is no general index, and in spite of a claim to the contrary, it was found difficult to trace items from volume to volume through the separate indexes, as the important references are not distinguished.

Summarising, the six volumes together constitute an indispensable work of reference to anyone interested in the growth of American industry, and the appendixes alone are a mine of statistical and other information and occupy about one-fifth of the first five volumes. As a guide to the working of tariffs and other industrial legislation, they should be of interest far outside the chemical field.

# THE PEACEFUL USES OF ATOMIC ENERGY

## REACTOR PHYSICS AND CHEMISTRY

By Dr. J. GAUNT and D. J. LITTLER
Atomic Energy Research Establishment, Harwell

PREVIOUS articles by Sir John Cockcroft and Dr. R. Spence on the Geneva Conference on the Peaceful Uses of Atomic Energy (see *Nature*, September 10, p. 482, and September 24, p. 574) have described the plenary sessions, and those sessions devoted to reactor development and chemical technology. The present article deals with the more specialized technical sessions in the fields of reactor physics and chemistry.

The sessions on reactor physics began with descriptions of the various techniques used for the measurements of neutron cross-sections; these included descriptions by American, Soviet and British scientists of mechanical velocity selectors, time-of-flight instruments, and methods for determining inelastic cross-sections. The papers which were read showed that the work had been proceeding on similar lines in all three countries. The delegates were interested to hear a description of a new type of neutron spectrometer developed in the U.S.S.R. A pulsed deuterium–tritium neutron source, embedded in a large block of lead, is used; by observing the neutrons a definite time after the source has been pulsed, one can select neutrons which have been moderated by elastic collisions in the lead and therefore have a particular energy. This technique should prove useful for measuring neutron absorption cross-sections in the so-called intermediate energy region, and will supplement experiments being made by another method at Harwell.

In later sessions, some of the results obtained by these techniques were described. Most of the cross-section values presented were ones which had previously been classified; they included the total and fission cross-sections of the three fissionable isotopes, uranium-233 and -235 and plutonium-239, for all neutron energies up to several MeV., and the absorption cross-section as a function of energy of the very important fission-product poison xenon-135. The cross-sections of the fissionable isotopes had been independently measured in Canada, France, Great Britain, the United States and the U.S.S.R., and the curves showing the variation of cross-section with energy agreed remarkably well in all cases. One interesting feature was that a small resonance in uranium-233 was only fully disclosed by combining all the data. Its presence had been suspected in each country, but in every case it was thought that insufficient data had been accumulated to be sure that the resonance was real.

The absolute values of the cross-sections of the three isotopes, uranium-233 and -235 and plutonium-239, showed some discrepancies. At the suggestion of the chairman of the session on fissionable isotopes, D. J. Hughes, the British, French, Soviet and American scientists met after the formal session to consider the thermal (2,200 m./s.) absorption and fission cross-sections of these isotopes. It was decided to prepare a set of 'world average values' for these cross-sections, which could be used as a means of co-ordinating reactor calculations based on them. The quoted errors of the world average values given here are based primarily on the spread in reported results and are sometimes larger than errors of specific quoted results:

| | $\sigma_{abs}$ (barns) | $\sigma_f$ (barns) |
|---|---|---|
| Uranium-233 | 593 ± 8 | 524 ± 8 |
| Uranium-235 | 698 ± 10 | 590 ± 15 |
| Plutonium-239 | 1,032 ± 15 | 729 ± 15 |

Almost a whole session was devoted to discussing what are the best values of the number of neutrons per fission and the number of neutrons per neutron captured for the three fissionable isotopes. Papers were read by British, American and Soviet physicists, and again it was found that there was good agreement on these hitherto classified numbers. It was shown that breeding with a positive gain-factor with a uranium-238–plutonium-239 system is not possible in either an intermediate or thermal energy reactor; but that breeding should be possible in a thermal reactor with the thorium-232–uranium-233 system. An important contribution from the United States was on the delayed neutrons following the fission of uranium-233 and -235 and plutonium-239; here, again, most of the information had previously been classified.

Several sessions were devoted to describing measurements of importance to thermal reactor design, such as slowing-down and diffusion-lengths in beryllium, graphite and water; resonance integrals for uranium and thorium; and exponential experiments made with uranium and the three moderators, graphite, light water and heavy water. Here there were contributions from India, Sweden, Norway and The Netherlands as well as from France, Great Britain, the United States and the U.S.S.R. An interesting paper was also read on the British zero-energy fast reactor (ZEPHYR), to which reference has already been made in Sir John Cockcroft's article. Papers were also read describing the work done on thermal homogeneous critical assemblies at Harwell and Oak Ridge; the latter paper described some very painstaking work done over a period of several years. Part of a session was devoted to the subject of fission-product poisoning, which is of importance in evaluating the reactivity lifetimes of thermal reactors; contributions from the United States, Great Britain and Canada were presented. The sessions on reactor physics closed with the reading of papers on reactor kinetics and reactor theory.

The sessions on chemistry, metallurgy and technology started logically with discussions on the natural occurrence of uranium and thorium. Each nation was originally invited to submit papers on the occurrence of these metals within its own territory, and a summary of all the data submitted was presented by P. F. Kerr for the United Nations, followed by a panel discussion between representatives of some twelve countries. In the subsequent session, methods of prospecting, including ground, aerial, aero-radiometric and radio-hydrogeological methods, were discussed. Although it appears that prospecting for uranium is now being carried out at a rate unparalleled for any other metal, S. H. U. Bowie and

C. F. Davidson (Great Britain) and A. H. Lang (Canada) stressed the need for a geological approach to the problem rather than the present tendency for "wildcat weekend schemes".

The sessions on the fission process and the chemistry of fission products and heavy elements demonstrated the vast amount of work of a fundamental nature that has been carried out since the first discovery of fission. During the course of these meetings, the names were publicly announced for the elements 99 (einsteinium), 100 (fermium) and 101 (mendelevium), and much interesting information was presented by Great Britain, the United States and the U.S.S.R. on the fundamental chemistry of elements such as ruthenium, technetium, americium and curium, while delegates from many countries took part in the discussion.

Three sessions were devoted to discussions on the effects of radiation on reactor materials, solids and liquids. Here again it was evident that, while a very considerable effort has been expended by many nations in an endeavour to obtain information of technological importance, much work of a purely fundamental nature has also been carried out, as exemplified by A. O. Allen and by C. J. Hochanadel (United States) in their contributions on the effect of radiation on water.

Although much information on the production of metallic uranium and metallic fuel elements was released by Great Britain and the United States for the Conference, only a limited number of papers could be presented orally. Of these, the paper by J. P. Howe described some of the extensive work being carried out in the United States on a large variety of potential fuel elements such as ceramics using uranium dioxide, uranium bonded in zirconium and a dispersion of uranium carbide in graphite, while G. E. Kaplan and G. A. Meyerson (U.S.S.R.) described the production of thorium by electrolysis of a fused salt and the powder metallurgy of this very important element.

In the sessions devoted to the production technology of special materials, particular attention was paid to graphite, zirconium, beryllium and heavy water. M. Benedict (United States) gave a condensed account of his extensive survey paper of production processes for heavy water and the economics of various methods, while I. Dostrovsky and Y. Lehrer (Israel) presented some interesting information on basic design equations for the distillation process in isotope-separation plants.

The sessions devoted to the study of separation processes for uranium and plutonium were supplied with much information from Great Britain and the United States which had hitherto been classified. This information was virtually complete and should be of immense value to other nations contemplating the design and operation of extraction plants. It covered not only the practical experience gained from the operation of existing extraction plants, but also surveyed the practical limitations of solvent extraction processes and the processing of aqueous homogeneous reactor fuels. Liquid-metal technology was also discussed from the point of view of the use of liquid metals for reactor coolants. The paper by M. A. Mikheyev on heat transfer of molten metals showed that the U.S.S.R., as well as Great Britain and the United States, is pursuing work on this subject with great vigour.

Finally, the chemistry and technology sessions ended with discussions on waste treatment and disposal; the contributions in these sessions coming from Canada, Great Britain and the United States provided interesting accounts of the disposal practices in these countries.

---

# FERTILITY IN FARM ANIMALS

THE importance of a high standard of fertility in farm animals is pointed by the fact that, on September 5, at Bristol, Section M (Agriculture) of the British Association spent a complete morning discussing the problems involved in it. Quite apart from the fact that a large proportion of farm animals, such as dairy cows, are kept simply because they breed and their productivity depends on their doing so, efficient animal production is closely related to regular high fertility in most other species and types of animal also. Furthermore, selection and improvement by breeding are dependent, if they are to be efficient, on the maximum number of offspring being produced. The problems associated with fertility were presented and reviewed in three papers: Dr. J. A. Laing, on standards of fertility; Dr. J. Hammond, on factors augmenting fertility; and Mr. A. F. Holt, on factors reducing fertility.

In discussing standards of fertility, it was pointed out that in pigs and sheep no absolute standards exist. The inherited differences in fertility between breeds of sheep and the manner in which inherent fertility is conditioned by environment can cause very wide variations in lamb production in normal circumstances from 100 to 200 per cent annually. Wide variations in fertility also exist between breeds of pigs with average litter sizes from seven to eleven, variation which is again increased by differences in management and husbandry. In the case of cattle, there do not seem to be the same inherited differences, but there are very great diversities which are associated with environmental factors. A distinction must be drawn between inherited fertility and inherited infertility. The differences in the former are referable to numbers of ova ovulated, whereas the latter is in general associated with specific anatomical abnormalities which prevent either male or female animals from breeding. It is for this reason that the number of lambs or the number of pigs born after each pregnancy can be varied by inheritance, whereas in cattle the twinning-rate is so low as to be insignificant in its effect on fertility. Inherited infertility also, while it is found in all species, is of low incidence and affects standards only in a minor way. The conclusion which has been reached by many workers that only small improvements in fertility can be achieved by selection and breeding for this character was questioned on the grounds that the statistical analyses made may not have been based on the correct premises. Certainly, very great improvements of existing standards should be possible by alterations in environmental conditions, and with them increases in productivity.

These improvements can be approached in two ways, either by the method of eliminating those factors which reduce fertility or by that of introducing new methods which enhance fertility beyond the physiologically normal level.

In the case of the bull and ram, the present method of dilution and storage of semen has greatly increased fertility, and further extensions of this method have been possible through the development of storage of semen at −79° C. Extension of the fertility of horses and boars, however, has until recently not been possible because of the lack of suitable diluents for the preservation of spermatozoa; but the use of glycine as a diluent for boar semen has recently been successfully developed, and preservation of spermatozoa by means of glycine diluents is now being applied under farm conditions, so that the fertility of the individual boar may be considerably increased.

Female fertility may be increased by stimulating the production of larger numbers of ova by means of injected gonadotrophic hormone. The ovulation-rate of the ewe can be raised in the normal breeding season by means of 500 I.U. of pregnant-mare serum (mare serum gonadotrophics) given four days before œstrus. Œstrus and ovulation can be induced in the summer ancestrous period by the injection of pregnant-mare serum following progesterone. This is particularly important because of the unproductivity of the ewe for half the year. This method marks an advance, for, until recently, hormonal methods of inducing summer œstrus in ewes have been unreliable, causing either ovulation without œstrus or vice versa, but rarely the two together.

The fertility of cows of high genetic value could be increased by the intra-uterine implantation of their ova in other less valuable 'incubator' cows. The practical difficulties associated with this method have not yet been solved, although such transplants have been made by surgical methods in many species, including the cow. If this method were possible, fertility and thus productivity could be multiplied by the transfer of gonadotrophin-stimulated fertilized ova from pre-pubertal cattle, because fertilized ova have been produced in this way from calves less than one month old.

Looking at the other side of the picture—the removal of factors reducing fertility—one of the most impressive features is the transitory nature of most forms of infertility, particularly in cattle. Recent surveys at cattle breeding centres have shown that about 5 per cent of herds experience widespread infertility annually, but only 1 per cent remain infertile for more than one year. Many of the associated factors are unknown, although climate and the effect of season of the year, age, size of herd and time of breeding in the œstrous period may be involved. The nutritional problems are particularly complicated, and there is now good evidence that the combined effects of phosphorus, calcium and vitamin D may be of considerable importance, although the complete and precise pathological processes involved have yet to be clarified. Infectious diseases, such as brucellosis and trichomoniasis, have been controlled by the introduction of suitable measures of preventive medicine and alterations in animal husbandry. Vibriosis, a disease the pathogenesis and diagnosis of which have now been clarified, will eventually be similarly dealt with. It is striking that in all types of disease which depress fertility, whether infectious or otherwise, and in all species of animal, one prominent pathological feature is early embryonic mortality. If the causes of this lesion could be determined, a great step forward would be taken towards the reduction of infertility and so to the increase of productivity.

---

# TRACE ELEMENTS AND PLANT GROWTH

AT the recent British Association meeting in Bristol, a joint session of Sections K (Botany) and M (Agriculture) was held on September 6, at which the subject of "Trace Elements and Plant Growth" was discussed. The session was opened with an introductory paper by Prof. T. Wallace (Long Ashton), who reviewed aspects of the subject of interest both to botanists and agriculturists, and illustrated the main points by reference to crop plants. He began by presenting a general picture of the content of mineral elements in plants, for which the term 'mineral status' might be used to express the resultant of the quantities and interactions of the elements present in the plant on its growth and metabolic activities. The mineral elements that occur in plants are generally classified into three groups: essential mineral nutrients; beneficial elements; and other elements. While the essential mineral nutrients comprise the most important group, the other elements are of importance and may present special problems both in the growth and utilization of plants.

The total number of mineral elements now regarded as essential for the growth of higher plants is thirteen, and these are usually divided into two groups, major and trace elements, purely on the basis of the amounts commonly found in plants. The grouping is as follows:

*Major*: nitrogen, phosphorus, calcium, magnesium, potassium and sulphur.

*Trace or minor*: iron, manganese, boron, copper, zinc, molybdenum and chlorine.

Chlorine is the last element to be proved to be essential and is tentatively placed in the trace element group, although it probably occupies a position intermediate between the two groups. In the subsequent sections of Prof. Wallace's paper the discussion was restricted to the six well-established trace elements—iron, manganese, boron, copper, zinc and molybdenum—all of which have been shown to be essential for a wide range of plants and to be of considerable importance in crop production.

After surveying the historical aspects of trace elements, dating from the experiments of Sachs and Knop about 1860, the special effects of trace elements in relation to deficiencies, excesses and interactions were outlined and illustrated by photographs. Prof. Wallace pointed out that the particular effects shown are not only of economic importance, but also are of use in assessing the mineral status of plants and in investigating special problems of plant nutrition, such as in the examination of factors causing injurious effects produced on many plants in acid soils.

An outline was given of the soil factors that are of special importance in influencing the supply of the trace elements in soils to plants, particular mention being made of the effects of $pH$, organic matter and drainage conditions. Availability of five of the six trace elements tends to decrease progressively with increases in $pH$ values, but the reverse holds for molybdenum. The effects of organic matter are complex, and the availability of manganese, copper and zinc may be seriously decreased by 'fixation' effects. Drainage effects are possibly largely due to changes brought about in conditions affecting oxidation and reduction in the soil. Efficient methods now exist for the control of deficiencies of all the trace elements in field crops, with perhaps the exception of iron, and for this element promising results have been recently obtained with iron chelates, such as the iron salt of ethylene diamine tetra acetic acid, used both as foliage sprays and as soil dressings. Methods for the control of excesses of the elements are not so satisfactory, particularly for copper and zinc, which among other effects produce a deficiency of iron.

Following Prof. Wallace's introduction, three papers were presented dealing with special topics of current research on trace elements. The first of these was by Dr. E. J. Hewitt (Long Ashton), who described the methods he has employed at Long Ashton to produce deficiencies of the trace elements in sand and water cultures, and in his investigations to establish the essentiality of further elements that might be expected to be needed by plants in trace amounts. The methods used involve several considerations that apply equally to investigations with higher plants and micro-organisms. Mineral element contamination, ranging from negligible to injurious concentrations, may occur at random from many sources. It should always be assumed to be present, and specific precautions should be adopted as routine measures to reduce it to a minimum. Ideally the culture medium should provide quantitatively known amounts of all the elements regarded as essential.

-Culture equipment and materials, comprising containers, water supply, solid media and nutrient reagents must all be specially selected and treated to eliminate likely impurities. Minimum concentrations of some known essential elements, for example, molybdenum, may need to be of the order of 0·000 005 parts per million to obtain severe deficiency effects. These levels may be achieved in water purified by ion-exchange resins or by distillation in 'Pyrex' apparatus. Specific nutrient purification methods should achieve 99·95 per cent efficiency of removal at initial concentrations of only a few micrograms per litre, without introducing physiologically active residues. Seed or inoculum inevitably provides elements essential to the species and may require initial depletion under deficiency conditions before a response can be observed. Atmospheric contamination may enter directly through foliage or by aeration treatments, and air-conditioned equipment may be necessary. Large-scale experiments greatly magnify the difficulties. Estimates of total mineral contamination and its sources are desirable, and for these chemical and spectrographic methods, radioactive isotopes and biological assays each have limited uses.

Many experiments to demonstrate the essential nature of mineral elements have exploited existing methods to the limits of their efficiency. The interpretation of negative results in such investigations should be limited to the statement that requirements, if any, are below the threshold set by the experiment. The most painstaking experiments often fail to eliminate traces of certain elements from the ash of the test organism. Tests of cobalt, nickel and vanadium omissions, using tomato in water culture, suggest residual contamination that is 10–100 times greater than expected from residual levels normally achieved for copper or molybdenum employing comparable techniques, and the levels found are within the known range of adequate supply for some essential micronutrients.

On the other hand, although some elements—for example, magnesium—are regarded as being generally essential, the absolute or qualitative requirements of organisms may differ for certain elements, or for a given element in different nutritional circumstances. Recent advances in knowledge of differences in the utilization of cobalt, molybdenum, vanadium and sodium in bacteria, algæ and fungi support this view, which is compatible with the effects of evolution on differences in specific properties of enzyme proteins. Beneficial elements may also be revealed, as although these are not essential, they may materially supplement growth or metabolic efficiency either under conditions of partial deficiency, or in the presence of the full complement of the known essential elements where two or more enzyme systems may have incompatible optimal requirements for a single element.

There is considerable scope for further investigation of these more specialized aspects of mineral nutrient requirements. The limits of existing techniques must be extended to lower thresholds of sensitivity for elements of uncertain nutritional status, and the range of organisms studied must be greatly increased.

Dr. D. J. D. Nicholas (Long Ashton) discussed the role of molybdenum in the nitrogen metabolism of plants and described investigations on the nitrate reductase system of higher plants and micro-organisms in which molybdenum has been shown to be the metallic component of the enzyme. The results have established for the first time a definite role of molybdenum in the metabolism of plants. The enzyme that catalyses the reduction of nitrate to nitrite in higher plants, fungi and some bacteria is a molybdoflavoprotein, which transfers electrons from reduced pyridine nucleotides via flavin and molybdenum to nitrate, and the latter is thereby reduced to nitrite. Molybdenum was identified as a constituent of the enzyme by the facts that increased enzyme activity was paralleled by an increase in its content in the enzyme, while other metals were without effect, and that it was possible to reactivate the dialysed enzyme specifically with molybdenum.

During nitrate reductase action, molybdenum undergoes oxidation-reduction changes involving $Mo^{6+}$ and $Mo^{5+}$. The valence-states of molybdenum, including $Mo^{6+}$, $Mo^{5+}$ and $Mo^{3+}$ prepared by paper chromatography, were used in experiments with the pure enzyme. $Mo^{5+}$ acts as an effective electron donor for the enzymatic reduction of nitrate, but $Mo^{6+}$ is without effect. $Mo^{3+}$ reduces nitrate non-enzymatically. It is unlikely that the chemical reduction of the nitrate ion by $Mo^{3+}$ is important for nitrate reduction in plants, because $Mo^{3+}$, which is readily oxidized to $Mo^{5+}$ in the presence of $Mo^{6+}$, has not been detected in plant tissues and the enzymatic reduction of nitrate involves $Mo^{5+}$ and $Mo^{6+}$ only.

It has not been possible to effect a non-enzymatic reduction of $Mo^{6+}$ to $Mo^{5+}$ or of $Mo^{5+}$ to $Mo^{3+}$ with either reduced tri- or reduced di-phosphopyridine nucleotide as the electron donor. Neither of the reduced nucleotides appears to reduce $Mo^{5+}$ to $Mo^{3+}$ chemically or enzymatically. $Mo^{4+}$ is unlikely to be important in metabolism, because it dismutes readily to Mo$^{4+}$ and Mo$^{6+}$ in the presence of a trace of water and is stable only in strong alcoholic solution. Nitrate reductase requires phosphate for maximal activity, so that the molybdenum is probably associated with the apoenzyme as a phosphomolybdate complex and probably undergoes oxidation-reduction in this form. The —SH groups in the enzyme may be important in binding the phosphomolybdate to the protein moiety.

The lower valence-states of molybdenum appear to be important in the initial stages of the fixation of atmospheric nitrogen by *Azotobacter*. The uptake of molybdenum and fixation of nitrogen per unit protein are greater when Mo$^{5+}$ is supplied to the organism instead of Mo$^{6+}$. When ammonium nitrogen is substituted for nitrate nitrogen in the culture solution, nitrogen fixation is retarded and there is no longer a differential uptake of molybdenum from culture solutions containing Mo$^{6+}$, Mo$^{5+}$, and Mo$^{4+}$ respectively.

In the final paper of the session, Mr. J. W. Hannay (Manchester) described his methods of culturing excised roots and reported some of the results he has obtained in studies with manganese, iodine and molybdenum. The rapid growth of the root from a small inoculum facilitates the production of micronutrient deficiencies, and the sterile nature of the cultures allows suspected metabolic intermediates to be supplied.

The culture of an isolated organ raises the possibility that the micro-nutrient requirements of such an organ might be different from those of the intact plant; and, in fact, it has been suggested by one worker that only copper and iron are essential for the growth of excised tomato roots. Other workers, however, have shown that molybdenum and zinc are essential, and Mr. Hannay has described methods by which the essentiality of manganese has been demonstrated. The manganese could not be replaced either by cobalt or nickel, both of which were toxic even at 0·005 p.p.m. either in the presence or absence of manganese. Thus copper, iron, zinc, molybdenum and manganese are essential for the growth of excised tomato roots, as they are for growth of the intact plant. The status of boron has not been determined, since 'Pyrex' culture flasks have been used throughout and these would probably supply the boron requirements of the roots.

In Mr. Hannay's experiments, iodine has been added as a micronutrient in the standard White's culture medium used. Omission of the iodine resulted in a 25 per cent reduction in the growth produced in one week; after three weeks, the growth was reduced by more than 50 per cent. The optimal concentration of iodine, added as potassium iodide, was between 0·1 and 0·5 p.p.m. iodine. If iodoacetic acid was substituted for potassium iodide, an even greater stimulation of growth occurred, the optimal concentration again being between 0·1 and 0·5 p.p.m. iodine. The results suggest that iodoacetate is active because of its iodine content, and this idea is supported by the fact that an —SH group inhibitor, *p*-chloromercuribenzoic acid, would not produce a similar growth stimulation in the absence of iodine. These effects of iodine are of interest in view of the concept of a 'beneficial element' proposed by Dr. Hewitt in his paper.

Investigations concerning the effect of the source of nitrogen upon the molybdenum requirement of excised tomato roots were also described. The techniques for using excess calcium carbonate as a buffer in the medium when roots are grown with ammonium nitrogen, and of making aseptic additions of nitrite nitrogen, were outlined. The interactions between nitrogen source and molybdenum requirement were as follows: when either nitrate or nitrite nitrogen was supplied, growth was very much reduced in the absence of molybdenum from the medium; when ammonium or amino-nitrogen was supplied as the sole nitrogen source, there was no significant difference due to molybdenum. These facts indicate that not only is molybdenum required in the nitrate reductase enzyme, but also in the system reducing nitrite. This latter point, however, requires further study. It has not been possible in these experiments to decide whether molybdenum may have any further role in plant nutrition other than in nitrogen metabolism.

# PRINCIPLES OF GAS REFRIGERATING MACHINES

By Dr. J. W. L. KÖHLER

Philips Research Laboratories, N.V. Philips' Gloeilampenfabrieken, Eindhoven

REVIEWING present-day means of producing cold, one is struck by the fact that refrigerators, that is, machines for producing cold, operate over only the temperature range between the ambient or room temperature and −80° C. A second point is that in most refrigerators the cold is produced by evaporating a liquid. It is amazing that of the many possibilities offered by Nature, only one is actually utilized. In this article, we give a survey of another method, which may provide a welcome extension of refrigerating technique[1].

## Fundamental Cycle

The cold is produced in this machine by the reversible expansion of a gas. The gas performs a cycle, during which it is compressed at ambient and expanded at the desired low temperature, the transition between these temperatures being accomplished by heat exchange between the gas going in the one direction and the other. The gas refrigerating machine is fundamentally a special case of the Stirling cycle (Robert Stirling, a Scottish minister, invented the air engine in 1816; the first actual refrigerating machine, based on the Stirling cycle, was described by A. G. Kirk[2]) whereby the compression and the expansion are alternating processes and the heat exchange already mentioned takes place in a regenerator. The $p$–$V$ diagram of the ideal cycle consists of two isotherms and two isochors, as shown in Fig. 1; it is to be noted, however, that the isochors may be replaced by isobars, or in general by any pair of lines which permit heat exchange by regeneration.

Fig. 2 shows stages in carrying out the ideal cycle. In this diagram, 1 is a cylinder, closed by the piston 2, and containing a nearly perfect gas. A second piston, the displacer 3, divides the cylinder into two

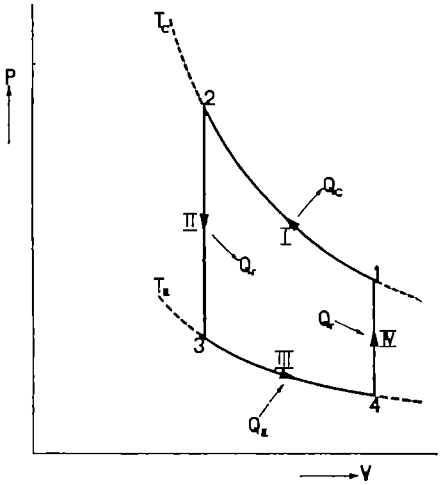

Fig. 1. $p$–$V$ diagram of the ideal Stirling cycle between the temperatures $T_C$ and $T_E$. At $T_E$ the amount of heat $Q_E$ is absorbed during phase III, at $T_C$ the heat $Q_C$ is rejected during phase I. The heat $Q_r$, rejected in phase II, is stored in the regenerator and absorbed in phase IV

spaces, 4 at room temperature and 5 at the low temperature, connected by the narrow annular passage 6. This passage contains the regenerator 7, a porous mass with a high heat capacity; the temperature in the passage is shown in the graph. The cycle, consisting of four phases, runs as follows: (I) Compression in space 4 by the piston 2; the heat of compression is discharged through the cooler 8. (II) Transfer of the gas through the regenerator to space 5 by movement of the displacer. The gas is reversibly cooled down in the regenerator, the heat of the gas being stored in the regenerator mass. (III) Expansion in the cold space by the combined movement of the piston and the displacer; the cold produced is discharged into the refrigerant in 9 and utilized. (IV) Return of the gas to space 4; thereby the gas is reheated, the heat stored in the regenerator being restored to the gas.

Actually, the discontinuous motion of the pistons implied here is not very practicable. Fortunately, little change is required if the pistons are actuated by a crank mechanism, with the condition that space 5 is leading in phase with respect to space 4. In this harmonic cycle the four phases are of course fused, so that the basic processes are more difficult to distinguish. The harmonic motion allows a high speed of the machine, causing the compression and the expansion to take place adiabatically; this entails only a small loss, as the compression ratio is rather low (approximately 2), due to the volume of the heat exchangers (dead space).

## General Characteristics

The properties of the ideal cycle are easily derived from the $p$–$V$ diagram. We find that, in contrast to the evaporation process, the output drops only gradually with temperature, so that the cycle is particularly suited to work over a large temperature ratio. Another important result is that the output is proportional to the pressure of the gas; this enables the design of machines with a high output for their dimensions by choosing a high pressure-level. As the ideal cycle is assumed to be completely reversible, its efficiency is equal to that of the corresponding Carnot cycle. In the actual process, the efficiency is reduced by losses, some of which are particularly important at a small temperature ratio (mechanical and adiabatic loss), whereas other losses reduce the output at very low temperatures (cold losses, for example, regeneration loss). This brings about an optimum working range, at present between −80° C. and −200° C.; future development, however, may extend this range.

## Regeneration

The practical realization of the Stirling cycle has only become possible with the development of efficient regenerators. The following argument demonstrates the severe conditions which must be met by regenerators in gas refrigerating machines[3].

Owing to imperfections, an amount of heat $\Delta Q_r$, the regeneration loss, is transmitted through the regenerator. As this loss reduces the effective cold production, we may compare it with the ideal production $Q_E$. For well-designed machines we find:

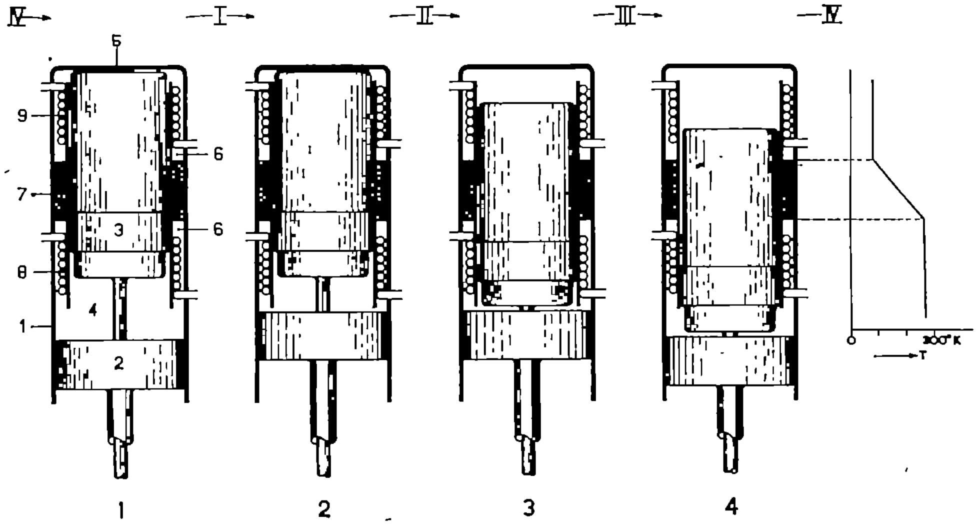

Fig. 2. The ideal Stirling cycle. The figure shows the different positions according to points 1–4 of Fig. 1. I–IV refer to the four phases of the cycle. The graph on the right shows the temperature distribution in the machine

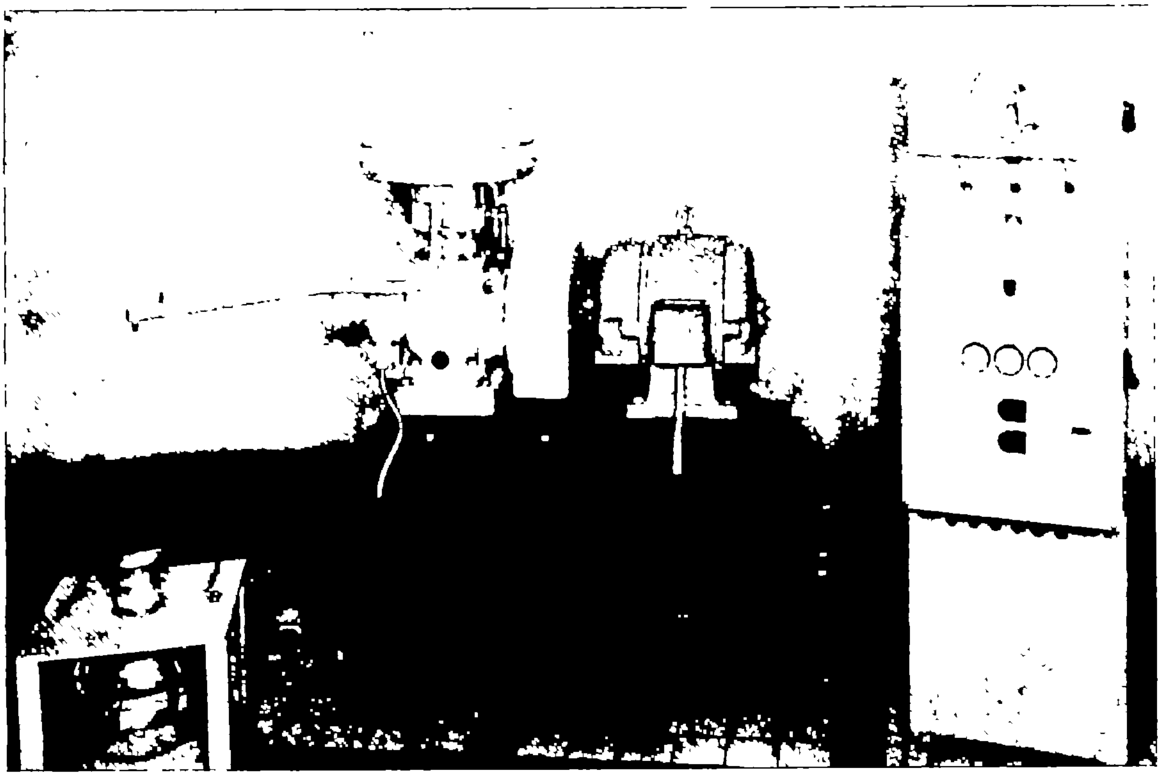

Fig. 3. The complete air liquefier with electric motor and control panel. The large hood on top of the machine contains the ice-separator, in which the ice and carbon dioxide are deposited; it must be de-iced once in 24 hr. The air is sucked in automatically and is discharged as liquid from the protruding delivery pipe

$$\frac{\Delta Q_r}{Q_E} \approx 7\ (1 - \eta_r)\frac{T_C - T_E}{T_E}$$

$T_C$ being the compression temperature (300° K.), $T_E$ the expansion temperature, and $\eta_r$ the efficiency of the regenerator.. Taking $T_E = 75°$ K., this reduces to:

$$\frac{\Delta Q_r}{Q_E} \approx 21\ (1 - \eta_r)$$

showing that a regeneration loss of 1 per cent entails a loss of 21 per cent in output (at 20° K. the result would be 98 per cent). Thus the lowest temperature that can be obtained is mainly determined by the quality of the regenerator.

It has been found that with a light, felt-like mass of very fine wire, regenerators can be prepared with efficiencies higher than 99 per cent (at frequencies as high as 50 c./s.). It should be borne in mind, however, that the regenerator acts as a resistance to the gas flow as well, so that in designing them there must be a compromise between regeneration loss, flow loss and loss by dead space. Finally, the heat capacity of the regenerator must lie above a certain value and the heat capacity of the gas must be independent of pressure (nearly perfect gas), requirements that are difficult to meet at very low temperatures.

## Applications

A first application of the new process is a machine working at −194° C. for liquefying atmospheric air.

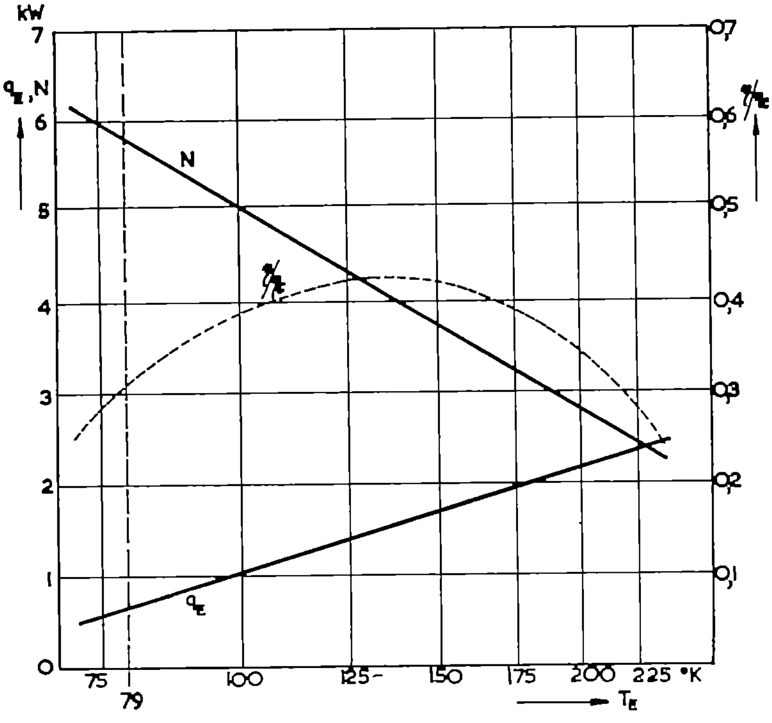

Fig. 4. Refrigerating capacity, power consumption and figure of merit of the air liquefier at different temperatures

The fact that the air to be liquefied need not be compressed makes this unconventional air liquefier very simple and easy to handle. Fig. 3 is a photograph of the complete installation (with hydrogen or helium as working fluid), producing 5·5 litres/hr. liquid air and designed for unattended use. The efficiency of this liquefier compares favourably with that of conventional types; particulars are given in literature quoted. Fig. 4 gives the refrigerating capacity, the power consumption and the figure of merit of this machine at different temperatures. It is clear from this graph that the air liquefier is only one application of the gas refrigerating machine, and that we may expect many more applications, in particular, in the temperature-range between −80° C. and −200° C.

# INTERNATIONAL ASTRONOMICAL UNION

## GENERAL ASSEMBLY IN DUBLIN

MORE than six hundred astronomers, from forty-one countries, attended the meetings in Dublin during August 29–September 3 of the International Astronomical Union, under the presidency of Prof. Otto Struve (Berkeley, California). The largest national delegation came from the United States, and there were also large groups from France, Germany and Great Britain. Among other representatives were about twenty from the U.S.S.R., the largest number of Russian astronomers yet to attend a meeting of the Union.

The International Astronomical Union was founded in 1920, holding its first meetings in Rome in 1922, and can claim to be one of the oldest and most successful of the international scientific unions. It was born amid political difficulties created by the First World War, and since then has had to contend with the growing tensions of the 1930's, the disasters of the 1940's, and the ill-feeling of the early 1950's. Despite these troubles, astronomers have held steadily to the belief that full and effective international co-operation is essential for the well-being of their science. In consequence, the Union has managed to survive and grow; it has a record of substantial achievement, and the recent meeting was attended by more astronomers, and was perhaps marked by more general cordiality, than any previous one.

Since 1920 astronomy has developed enormously. Perhaps it may be recalled that at that time the structure of the Milky Way system was mostly unknown, the extragalactic character of the spiral nebulæ was not universally accepted, interstellar matter was regarded as quite negligible, and the theoretical basis of present-day astrophysics was only just beginning to come into existence. It is not entirely surprising that the original organization of commissions, each dealing with its own special branch of the subject, which has worked tolerably well for thirty-five years, is now requiring reform. At the beginning there were about thirty commissions, each a fairly compact group of about a dozen members. This year there were forty commissions, with an average membership of about forty, as well as fifteen sub-commissions. Some commissions have become much too large to be effective and a great deal of their work has in recent years been done by the sub-commissions. To meet this difficulty of unregulated growth, the General Assembly has taken the important decision that in future the International Astronomical Union shall consist of a main body of ordinary members and a comparatively small body of commission members. The details of the transition from the present arrangements have still to be worked out.

In his address at the inaugural ceremony this year, Prof. Struve reminded his audience of the speech of his predecessor Prof. W. W. Campbell, in 1925, in which it was pointed out that the Union was not to be an international society to provide the opportunity for the reading of papers describing work already done and results already obtained, this function being well taken care of by existing national societies, but should have other and broader aims, especially "(1) To facilitate the relations between astronomers of different countries where international co-operation is necessary or useful; (2) To promote the study of astronomy in all its departments". At recent meetings there has been a tendency to forget these early ideals and to devote too much time to the reading of formal papers in rapid succession, a procedure calculated to give early intellectual indigestion to the great majority of hearers. Prof. Struve's remarks were welcomed by the growing body of members who have deplored this tendency, and who have themselves generally found greater profit in informal discussions, both within commissions and without, with colleagues from distant countries whom they rarely see except at these meetings.

In the commissions dealing with solar and terrestrial matters, considerable attention was given to plans for the International Geophysical Year of 1957–58. Some members raised doubts as to the practicability of completing with the available labour force all the ambitious and comprehensive series of observations proposed, still less the subsequent reductions and computations. On one hand, astronomical problems are greatly increasing in number and complexity and demand an ever-increasing number of workers; on the other, some countries are now facing a famine in young scientists having a basic training in mathematics or physics, and this is already causing serious concern to the directors of observatories and other astronomical institutions. This growing difficulty affects not only the coming International Geophysical Year but also nearly all branches of observational astronomy, especially those involving long series of observations or measurements.

A number of joint meetings and symposia were held, for the most part well organized and with plenty of time for discussion. The subjects included non-stable stars, the large-scale structure of the galactic system, solar flares, photoelectric image tubes, turbulence in stellar atmospheres, and fundamental stars. The discussions showed generally a commendable restraint in the interpretation of new observations and discoveries, with the emphasis more on the bewildering complexity of astronomical phenomena than on our progress in understanding them. There were no signs of the pseudo-omniscience which often colours popular writing in astronomy and which does the subject no little harm with critical readers.

Among recent results announced at the meetings a few call for special mention. Photographs of the solar spectrum showing extremely clearly the variation of line shifts and line profiles over the coarse granulation have been made at the McMath Observatory with a new large grating spectrograph giving a resolving power greater than 500,000. Remarkable films of solar flares, also photographed at the McMath Observatory, aroused much interest. Recent rocket flights in the United States have provided photographs of the solar spectrum into the ultra-violet beyond $L\beta$. The rotation of the Large Magellanic Cloud has been measured at the Radcliffe Observatory, Pretoria. Evidence for the very recent formation of certain stars has been found by workers at the Lick Observatory. Photometric measures made at Mount Wilson of the old nova, *DQ* Herculis, now an eclipsing binary, have shown at some phases a remarkable regular pulsation with a period of a little more than one minute.

A few resolutions of more general interest may be mentioned out of the many submitted by commissions and approved by the General Assembly. With regard to notation, A is to be preferred to Å as an abbreviation for the angstrom unit; 'kayser' is rejected in favour of cm.$^{-1}$. Two proposals of the International Committee on Weights and Measures were endorsed, one relating to a re-definition of the metre in terms of the wave-length of the red cadmium line, the other (which may very soon be made obsolete by recent work with cæsium resonators) defining the second as 1/31 556 925·975 of the tropical year for 1900·0. A number of recommendations were made concerning secondary wave-length standards of iron, neon, and argon. Strong support was given to the efforts of the International Scientific Radio Union to obtain frequency-bands for the use of radio astronomers, free of interfering radio transmissions.

The recognition that photoelectric image tubes may ultimately give considerably greater speed for faint sources than the ordinary photographic process, and that they promise to be of the greatest importance to astronomers, has led to the formation of a new sub-commission to encourage developments in this field. Other new sub-commissions have been formed on 'seeing', on meteorites, on variable stars in globular clusters, on the determination of the galactic pole and the zero of galactic longitude. Two commissions and four sub-commissions have been abolished.

The new president of the Union is to be Dr. A. Danjon, director of the Paris Observatory. He will hold office until the 1958 meetings, which on the invitation of the National Academy of Sciences of the U.S.S.R. will be held in Moscow. The U.S. National Committee has issued an invitation to hold the 1961 meetings in Pasadena.

At the concluding session of the General Assembly, warm appreciation was expressed of the hospitality of the Irish Government, of University College, the Institute for Advanced Studies, the Dunsink Observatory, and other institutions in Dublin. That the meetings were so successful and enjoyable was due in large part to the efforts of the Dublin organizers and their helpers, efficiently and energetically led by Prof. and Mrs. H. A. Brück. R. O. Redman

# OBITUARIES

## Prof. V. A. Dogiel

Prof. Valentine Alexandrovitch Dogiel, who died on June 1, was the most outstanding Russian protozoologist of our times. Born in Kazan on March 10, 1882, he was the son of the eminent histologist, Prof. A. S. Dogiel, whose investigations on the minute structure of the nervous system are known throughout the world. V. A. Dogiel received his training in protozoology from V. T. Schewiakoff, whom he succeeded in 1913 as professor of invertebrate zoology in the University of St. Petersburg (now Leningrad), a post which he occupied until the end of his days. On his election as corresponding member of the Academy of Sciences of the U.S.S.R. in 1939, Dogiel also took charge of the protistological laboratory of its Zoological Institute.

Among Dogiel's earlier works (1916–23), those dealing with the parasitic flagellates of termites are noteworthy; but his most important contributions concern the systematics, morphology, and evolution of the Ophryoscolecid ciliates of ruminants. Dogiel's protozoological work culminated in the publication of a remarkable treatise on "General Protistology" (1951), providing a comprehensive, critical account of the fundamental principles and problems of protozoology.

From 1930 onwards Dogiel's researches were directed to the ecological aspects of parasitology, especially the effect upon the parasitic fauna of changes in the environment and physiology of their hosts. In 1941 he produced a "Textbook of General Parasitology", a second edition of which appeared in 1947. This book, which is devoted to the biology of parasites, is an outstanding contribution to parasitological literature, unique in conception and masterly in presentation. Dogiel was also the author of a "Textbook of Invertebrate Zoology" (four editions, 1934–47) and of a "Handbook of Comparative Anatomy of the Invertebrates" (1938–40), both of which are standard university text-books in the U.S.S.R. Finally, a year before his death (1954) he published a book on "Oligomerization of Homologous Organs: One of the Main Paths of Animal Evolution", in which he develops the idea that various groups of Metazoa have evolved by a gradual diminution, or oligomerization, in the number of homologous and homodynamic organs which were present in their ancestors.

During the forty-two years of his tenure of the chair of zoology in Leningrad, Dogiel built up a school of protozoology and parasitology, to which numerous students (including the present writer) owe their training in these subjects.

C. A. Hoare

## Prof. C. F. W. McClure

Prof. C. F. W. McClure, the distinguished American comparative anatomist and embryologist, whose death has recently been announced in his ninetieth year, was born in Cambridge, Massachusetts, in 1865. After an undergraduate career in Princeton, he studied at Columbia University in New York and in Berlin, Kiel and Würzburg. His academic career, however, was essentially linked with Princeton, where he was successively instructor in biology and assistant professor. In 1901 he was appointed to the chair of comparative anatomy in Princeton, and held that professorship with great distinction until his retirement in 1934.

In his early investigative work McClure inclined to neurology, and he published work on the brain of primitive vertebrates and on the structure of nerve cells in molluscs. His association with Prof. G. S. Huntington, however, led his interests into the field of the morphology and the functional anatomy of blood vessels and the lymphatic system. The collaboration led to classic accounts of the development of the mammalian inferior vena cava, accounts which really deserve the adjective exhaustive. The work with Huntington also resulted in a large number of publications on the early differentiation of lymphatic vessels. These contributions, in which it was insisted that lymphatic vessels can differentiate *in situ* from the embryonic mesenchyme, represented one side of a controversy that shook American anatomy during a period of years, for Dr. Florence Sabin's point of view, that lymph vessels arose only by centrifugal extension of endothelium from veins, was strongly supported by the powerful Johns Hopkins group of investigators. Strangely, the polemics on this problem were almost completely restricted to workers in the United States, possibly because of the preoccupation of European anatomists during the First World War. It was, however, a rewarding controversy, out of which much knowledge and some new techniques emerged.

McClure had been president of the American Association of Anatomists and for many years was a member of the Anatomical Society of Great Britain and Ireland. His distinction in his chosen field of work was such that he was included in the Cattell group of the leading thousand students of science of the United States as early as 1906.

J. D. BOYD

## Prof. C. T. Brues

CHARLES THOMAS BRUES was born in West Virginia in 1879, took his first degree at the University of Texas, and briefly held appointments at Columbia, with the U.S. Department of Agriculture, and at the Milwaukee Public Museum. At the age of thirty, he went to Harvard as instructor in entomology under Wheeler, and he spent the remainder of his working life there. To be an entomologist in 1909 meant to be a systematist; and Brues was soon a recognized authority on several families of Hymenoptera and Diptera. During this phase he published his catalogue of African Braconidae, the volume on Phoridae in the Genera Insectorum and, with A. L. Melander, the first edition of their well-known "Key to the Families of North American Insects". But Brues was also a naturalist and his interests gradually developed along two principal lines: the fauna of hot springs, and the correlation of systematic affinities with food habits. Food selection by insects increasingly occupied his attention. He wrote several important papers about it, interesting and valuable both to economic and academic entomologists; and finally, in 1946, summarized the whole field in his useful book, "Insect Dietary".

As a teacher of graduate students at the Bussey Institution, Brues was characterized by his helpfulness. His room was always open and he seemed cheerfully ready to put aside his own work and to lend himself, his mind, hands, time and tools, to his students. He was skilful in many small crafts and his skill was there to be called upon. In conversation and at symposia he rarely criticized, but was ready with useful suggestions. This willing disposition led Brues to undertake much extra work. Single-handed he edited thirty-six annual volumes of the entomological journal *Psyche*, and he served on innumerable boards and committees.

Brues was a man who helped where help was needed without counting the cost to himself or looking for any return. His former pupils and colleagues in many parts of the world will hear with regret that he died on July 29 in his seventy-seventh year, and will think of him with gratitude and affection.

GEORGE SALT

## Dr. S. G. P. Plant

DR. S. G. P. PLANT, who was senior lecturer and demonstrator at the Dyson Perrins Laboratory and secretary to the Delegates of the Oxford University Museum, died at Oxford on September 10.

Sydney Glenn Preston Plant was born at Leicester in 1896. He was educated at Wyggeston Grammar School and, in 1915, went up to Oxford as a Scholar of St. John's College, where he read for the final honour school of chemistry. As a young graduate he worked first under Dr. N. V. Sidgwick and later, as a senior demy of Magdalen College, under Prof W. H. Perkin. He became a lecturer and demonstrator at the Dyson Perrins Laboratory, and since 1928 he had also been secretary to the Delegates of the Oxford University Museum. He served on the Council of the Chemical Society and on its publication committee, and he contributed many papers to its journal. He had, for many years, been treasurer of the Ashmolean Natural History Society.

Dr. Plant's interest in indoles and carbazoles grew out of his early work with Perkin, and he and his pupils have contributed much to our knowledge of this field of heterocyclic chemistry. He published a long series of papers on the substitution and addition reactions of the indole nucleus and the determination of the position of substituents in indoles and carbazoles. It is worthy of note that he discovered some of the first-known covalent derivatives of the alkali metals, compounds of great interest to Sidgwick in his early work on the electronic theory of valency.

But it is, perhaps, as a lecturer and tutor that Plant will be best remembered. His great love of chemistry and his outstanding powers of lucid exposition have inspired, year after year, numbers of undergraduates; many of them began their researches with him and are better chemists for the excellent training they received under his keen and kindly supervision. He found scope for his real flair for organization at the Museum, and there, too, his unfailing good judgment, his tolerance and his delightful sense of humour stood him in good stead. He was as adept at dealing with the gratuitous communications of the discoverers of perpetual motion as with the everyday business of the Museum. A quiet and kindly man, he was liked and respected by all who knew him; he will be long remembered in Oxford, particularly at the Dyson Perrins Laboratory to which he gave such devoted service.

He married, in 1924, Winifred, daughter of William Crawford of Leicester. He is survived by her and by their two daughters.

J. C. SMITH
M. L. TOMLINSON

# NEWS and VIEWS

## Microbiology in the Department of Agriculture, Canada: Dr. A. G. Lochhead

Dr. A. G. Lochhead retired on June 21 from his post as chief of the Bacteriology Division, Science Service, Department of Agriculture, Ottawa, Canada, to devote his full time to research. Dr. Lochhead studied first at McGill University; during 1912 he completed the requirements for the Ph.D. degree at the University of Leipzig, but the outbreak of the First World War not only prevented his receiving the degree but also resulted in his internment in Germany for the duration of the War. However, his academic work and thesis were accepted by McGill University on his return to Canada in 1918. After lecturing in bacteriology at Macdonald College, McGill University, he left academic work for several years and gained valuable experience in industry by joining the staff of the Canadian Milk Products, Ltd., Toronto, and the Malt Products Company of Canada, Ltd., as bacteriologist-chemist. For a year he was lecturer in biochemistry in the University of Alberta. In 1923 he joined the Department of Agriculture as chief of the Division of Bacteriology, Experimental Farms Service. With the amalgamation in 1938 of the Dairy Research Division of the Dairy and Cold Storage Branch, he became chief of the Division of Bacteriology and Dairy Research. Through his leadership the Division has become widely known as a centre of fundamental research in soil microbiology, especially in regard to the relationship between the soil microflora and plant roots, and for his pioneering investigations on the classification, nutrition and growth factor requirements of the bacterial population of the soil. This devotion to the study of the soil microflora has not prevented his attacking other problems in microbiology and achieving recognition in specialized fields such as that dealing with the description, classification, nutrition and metabolic activities of sugar-tolerant (osmophilic) yeasts, with the microbiology and fermentation of honey, with the etiological agents of foulbrood of the honey bee and with halophilic bacteria. His rare critical faculties, his keen logic and his acute powers of observation have been combined with a most enviable talent for writing; his gentle and courteous treatment of everyone with whom he comes in contact has made him loved by all. He was president during 1953–54 of the Canadian Society of Microbiologists.

### Dr. H. Katznelson

Dr. H. Katznelson, principal bacteriologist of the Bacteriology Division, Science Service, Department of Agriculture, Ottawa, Canada, has succeeded Dr. A. G. Lochhead. Dr. Katznelson was born in a Russian village near the Polish border in 1912. At the age of eight his family settled in Vancouver, B.C., Canada. Katznelson studied bacteriology at the University of British Columbia, where he specialized in soil bacteriology, and at Rutgers University. This was followed by a year at Cornell University, and at the outbreak of the Second World War he returned to Canada to join the staff of the Division of Bacteriology and Dairy Research, Science Service, under Dr. Lochhead. Although Dr. Katznelson's main interest was in soil microbiology, he was able to carry out studies on a variety of problems ranging from antibiotics and bacterial viruses to diseases of the honey bee. His contributions to the control of these diseases, including the use of fumagillin to control Nosema disease and of antibiotics such as terramycin for American and European foulbroods, are well known. During the War he was engaged, in co-operation with the National Research Council of Canada, in studies on the microbiological production of 2,3-butylene glycol, a precursor of synthetic rubber. After this he turned to bacterial nutrition and physiology, with a few sorties into dairy bacteriology, where he and others on the staff demonstrated the significance of bacteriophage and antibiotics in cheesemaking. His own interest in bacterial viruses led to the development of a diagnostic procedure for detecting bacterial plant pathogens in seed which is used in various countries. After spending a year studying bacterial metabolism at Stanford University, Katznelson was made head of the Unit of General Agricultural Microbiology. He is at present particularly interested in problems of soil microbiology, halophilic bacteria, the metabolism and diagnosis of bacterial plant pathogens, diseases of the honey bee and tobacco fermentation.

## Physical Chemistry in the University of the Witwatersrand: Prof. J. O'M. Bockris

Prof. J. O'M. Bockris has been appointed to the newly created chair of physical chemistry in the University of the Witwatersrand, Johannesburg. Prof. Bockris graduated in 1943 from the Imperial College of Science and Technology, London, and continued there, working on electrode processes. In 1945 he was appointed to the staff of the College; for eight years from 1946 onwards he led a large research team on electrochemical problems, and this team carried out work in the following fields: the evaluation of the effect of trace impurities on electrode processes; the evaluation and application of diagnostic criteria in the determination of the mechanism of electrode processes (particularly in hydrogen and oxygen evolution); the technique of quantitative physico-chemical measurements at temperatures up to 2,000° C., leading to the establishment of the ionic nature and detailed lattice structure of the liquid silicates; and the application of statistical mechanical methods in electrochemistry—for example, the absolute calculation of electrode reaction-rates, the theory of salting in, and the mechanism of proton transport. Some work of an applied electrochemical nature was also undertaken, supported by both British and United States government and industrial bodies. During 1953–54 Prof. Bockris held a visiting professorship in the University of Pennsylvania and was later appointed professor of chemistry there. He is co-author of a text-book of electrochemistry, editor of "Modern Aspects of Electrochemistry", and co-author of the *Proceedings* of the International Committee for Electrochemical Thermodynamics and Kinetics.

## New National Parks in Great Britain

Designation orders have been made by the National Parks Commission for the ninth and tenth national parks, the orders being still subject to confirmation by the Minister of Housing and Local Government. The parks in question are the Northumberland National Park, incorporating the Forestry Commission's Border Forest Park, and the Brecon Beacons National Park. The Northumberland National Park comprises most of the upland country of Northumberland, from the Cheviots in the north to the Roman Wall in the south; part of its western boundary marches with the Forestry Commission's Kielder Forest, and this forest and the adjoining ones of Kershope in Cumberland and Newcastleton and Wauchope in Roxburghshire have been declared a national forest park, to be known as the Border Forest Park, by the Forestry Commission. The forest plantations will be opened to the public as soon as is practicable; in some cases this stage has already been reached, but new plantations will have to be protected for a number of years to come. The Brecon Beacons National Park, which comprises a total area of approximately 515 square miles, lying within the counties of Brecon, Carmarthen and Monmouth, is the third such park in Wales. It is one of the lesser-known of Britain's mountain areas, but none the less contains some of the finest scenery of South Wales, and indeed of Great Britain. The River Usk offers some of the finest salmon-fishing outside Scotland, and there is also fishing in the Llangorse Lake under the shadow of the Black Mountains, where many varieties of wild fowl are to be found. Some old and interesting towns lie within the park, including Brecon itself with its cathedral and the once-walled market town of Hay-on-Wye; sites of Roman and ancient British settlements abound, and there are several fine Norman and medieval castles, interesting churches and country houses.

## Research in the Belgian Congo

Workers at the Institute for Scientific Research in Central Africa, Bukavu, Belgian Congo, have produced more than three hundred and fifty original papers in the biological, social and physical sciences since 1948. Those directing the policy of the Institute decided at the outset not to publish a special journal, but to send their contributions to recognized periodicals, usually in Belgium although, where appropriate, in other countries also. They felt that a separate journal would contain too diverse a collection of papers to be generally useful and might tend to isolate the workers at the Institute, already geographically at something of a disadvantage, from their fellow scientists in other countries. The Institute has now started to issue quarterly its *Folia Scientifica Africae Centralis* (1, No. 1; 1955). This is not intended to compete with existing publications, but to supplement them and at the same time to make it easier for readers to grasp the scope of the work of the Institute. Four reasons for producing this publication are given. First, it will contain reports on the current programmes of the different sections, written in French and Flemish with a summary in English. Secondly, brief preliminary notes on new discoveries will be printed in French and English. Thirdly, there will be résumés in English of some of the more important papers by workers at the Institute appearing in Belgian and foreign journals. Finally, there will be annual lists of titles of new papers; the first number has a supplement of 360 titles, covering the period from 1948 to December 1954.

## Centro Appenninico, Terminillo: Biological Research Station in the Apennines

Some years ago the Italian National Research Council, at the instigation of Prof. Carlo Jucci, professor of zoology in the University of Pavia, decided to set up on Mount Terminillo, in the Apennines, a biological research station concerned with the pure and applied aspects of agricultural science, especially in their relation to the mountains (see *Nature*, 163, 811; 1949). This station, known as the Centro Appenninico, Terminillo, was formally inaugurated in August last year, and its work is now in full swing. It is situated in Terminillo, a village on the middle slopes of the mountain of the same name, which is a winter sports and also a summer resort, and for this reason enjoys good road communications, the bus trip from Rome, via Rieti, taking about three hours. The station stands on sloping grassland at 5,700 ft. (1,730 m.) at the lower limit of the zone of sub-alpine vegetation which extends to the top of the mountain at 7,300 ft. (reached in 1¼ hr. on foot). The winter climate is severe, with patches of snow still remaining on the mountain as late as May. The summer is never unduly hot but usually very dry, the rainfall being largely confined to the winter months. The Centre includes a meteorological station.

Cultivated plots for research purposes (mostly terraced owing to the steep slopes) are available close to the station itself, and also at 3,500 ft. half-way down to the plain; arrangements are being made for the use of a plot on the plain itself (about 1,200 ft.). There are six small laboratories equipped for standard work in microbiology, biochemistry, entomology, agrarian genetics, cryptogamic botany, cytogenetics and also physics. There are also a small museum and library. Board and lodging are available on the premises. The work so far undertaken at the Centre has been mainly concerned with the genetical study, and the improvement by selection for mountain environments, of crops which are important, or potentially important, to a hill population—especially the potato and the tomato. Hill pasture improvement has also been studied, and, as a minor mountain industry, the cultivation of medicinal herbs. It is hoped that the Centre will in time become well enough known abroad to attract numerous foreign workers in a much wider range of scientific activities, and assume an increasingly international character. Already a number of scientific meetings have been held there. Those interested in the Centre should write to the director, Prof. Carlo Jucci, at the Istituto di Zoologia della Università, Palazzo Botta, Pavia.

## World Power Conference: Report for 1954

The annual report for 1954 of the World Power Conference (pp. 17. London: World Power Conference, 1955) records the admission to membership of Paraguay, Spain and Thailand at the July 1954 meeting of the International Executive Council, bringing the membership to forty-three. The Brazilian Sectional Meeting of the Conference was held at Petrópolis, Rio de Janeiro, during July 25–31, 1954, being attended by 522 members from thirty-four countries, and the bound transactions were due for publication this year. The fifth World Power Conference will be held in Vienna during June 15–23, 1956, and a summary of the technical programme is appended to the report. "Statistical Year-book No. 7" of the Conference was published in July 1954, and the usual list of publications issued, or to be issued, under the auspices of the International Executive Council is also appended to the report, which includes a note on the twenty-first executive meeting of the International Commission on Large Dams of the World Power Conference. A new edition of the "List of National Committees and Representatives" was published in June, and the British National Committee has issued a list of twenty-six papers to be presented at the Fifth World Power Conference: these include three dealing with nuclear energy. Sir John Hacking was re-elected vice-chairman and Mr. F. G. Brewer honorary treasurer of the Committee at its recent annual general meeting, and Mr. C. E. Iliffe has been appointed to serve on the Committee as representative of the United Kingdom Atomic Energy Authority. A third impression of the fifth edition of "Technical Data on Fuel" was published in June.

### Statistical Aspects of the Nucleus

The proceedings of the conference on "Statistical Aspects of the Nucleus", held at the Brookhaven National Laboratory, Upton, New York, during January 24–26, 1955, were tape-recorded, and the uncorrected report of the talks and discussions produced from the recording has recently been published (pp. 113; obtainable from the Office of Technical Services, Department of Commerce, Washington 25, D.C.; 1955; n.p.). The conference consisted of four sessions devoted to low-energy scattering, elastic scattering, inelastic scattering and reactions I (residual nuclei in discrete states), and inelastic scattering and reactions II (residual nuclei in continuum states). The chairmen were E. P. Wigner, K. M. Watson, L. Wolfenstein and V. F. Weisskopf, respectively, and the speakers were E. Vogt, R. G. Thomas, K. M. Watson, D. S. Saxon, H. Feshbach, H. McManus and P. C. Gugelot. The proceedings concluded with a summing up by V. F. Weisskopf. The talks were obviously stimulating and produced lively discussion, which is all faithfully reproduced; but in the privacy of one's study the printed report appears to lack conciseness, and the essential points made by the speakers are lost in a bewildering mass of question and answer. As is pointed out in the foreword, editing was kept to a minimum in order to make the report available rapidly; but it is open to question whether the usefulness of the report has not been jeopardized by this course.

### Biochemical Activity of Pea-Seedling Mitochondria

D. D. Davies has reported the isolation of a diphosphopyridine nucleotide-specific *iso*citric dehydrogenase from pea-seedling mitochondria, a tenfold purification having been effected (*J. Exp. Bot.*, 6, No. 17, 212; 1955). In the presence of manganese the enzyme catalyses the oxidative decarboxylation of *d-iso*citrate to α-oxoglutarate and carbon dioxide, but under similar conditions does not catalyse the reverse reaction. Evidence is presented indicating that —SH groups of the enzyme are essential for activity. The properties of the enzyme are described.

### Reactions to Potato Virus Y

An account has been given of the reactions of certain Solanaceae to strains of potato virus *Y* by J. Munro (*Canad. J. Bot.*, 33, No. 4, 355; 1955). Strains of potato virus *Y* that were not clearly differentiated from each other by their reaction on potato varieties were shown to be separate entities by the differing reactions that they caused in several other solanaceous species. One strain did not infect *Physalis floridana*, but this same strain caused necrosis and a severe distortion of the young leaves of *Nicotiana sanderae*. After infection with certain other strains, *N. rustica* showed leaf-drop streak symptoms; this observation has not been previously reported. An avirulent strain in all potato varieties and seedlings tested so far caused a severely necrotic disease in *N. tabacum* and other *Nicotiana* species. The author notes that isolates of potato virus *Y* can only be recognized as mutants when they have ceased to cause the symptoms peculiar to this virus in certain homozygous hosts. During the course of this work the different strains remained constant by this criterion, and there was no evidence that mutations or changes frequently arise from this virus. However, the fact that several distinct strains were picked up in the field without difficulty indicates that changes may commonly occur.

### Cytology and Taxonomy of Ceylon Pteridophyta

As a further contribution to our understanding of the relationships between cytology and evolution in pteridophytes, I. Manton and W. A. Sledge (*Phil. Trans. Roy. Soc.*, B, 238, 127; 1954) have made a considerable study of fern material, largely collected by them in Ceylon, but also from other countries. In all, in the present work, cytological observations on 155 entities, referred provisionally to about 140 existing taxa in the fern flora of Ceylon, together with some sixty-nine entities from other sources, chiefly Malaya, are reported. A list of chromosome numbers is given, with an indication of the ploidy, or possible ploidy, of each species. The paper is illustrated by some silhouettes of plants, or leaves, and by a large number of diagrams and photographs of chromosomes. In discussing their findings, the authors consider that the new facts justify the view that cytology "will be at least as helpful in unravelling groups of difficult species in the tropics as it has long been known to be in temperate latitudes". The cytological data are considered in relation to the taxonomic systems of Copeland and of Holttum, and in a number of species and genera the authors have been able to indicate the need for revision. The distinctness of a number of little-known species has been confirmed, and apogamy has been demonstrated in a number of species. Two cases of putative intergeneric hybrids, from Ceylon and Malaya, have been investigated with confirmatory results. In the light of the new cytological information, the splitting of two of Copeland's families is recommended.

### Oil Reserves and the Petroleum Industry during 1954

The Annual Review for 1954 of the Esso Petroleum Co., Ltd., discloses some interesting economic facts concerning the industry generally and, in particular, the position of oil in Great Britain. Production of crude oil (world total) in 1954 was 2 per cent greater than in 1953, reaching 12·2 million barrels daily, due largely to progressive developments in the Middle East. Proved reserves of crude oil increased in 1954 by an amount more than enough to compensate for the total quantity of oil extracted. It is estimated that proved reserves "in the free world" amount to 147,000 million barrels (30 years consumption), of which the Middle East is likely to produce two-thirds. In Great Britain the growth of petroleum exports rose from a value of £6,900,000 in 1949, or one-seventh of the amount for coal, to £84,200,000 in 1954. Five years ago Great Britain refined less than half the petroleum products consumed. By 1952 the gap was closed. To-day there is a good surplus of home-refined products available for export.

### Coryndon Memorial Museum, Nairobi: Report for 1954

The annual report for 1954 of the Coryndon Memorial Museum, Nairobi (pp. 24+3 plates; 1955;

1*s*.), mentions that the continued state of emergency throughout the year has again been responsible for fewer visitors; but in view of the fact that few Africans could enter Nairobi, the reduction was not so much as was anticipated. Much curatorial work was accomplished, especially the development of a new Hall of Mammals, and work on transforming a large room into a Bird Gallery was in progress. Many important field trips were made for collecting, especially to a part of East Africa otherwise difficult of access and of great botanical interest. A well-preserved hand of a Miocene ape was found in blocks of limestone at Rusinga, and a nearly complete skull of a lemuroid was another important discovery. All this material is now being closely examined by a group of specialists.

## The Night Sky in October

FULL moon occurs on Oct. 1d. 19h. 17m., U.T., and new moon on Oct. 15d. 19h. 32m. The following conjunctions with the Moon take place: Oct. 11d. 16h., Jupiter 6° N.; Oct. 14d. 09h.; Mars 6° N.; Oct. 17d. 00h., Venus 4° N.; Oct. 18d. 05h., Saturn 4° N. In addition to these conjunctions with the Moon, Mercury is in conjunction with Venus on Oct. 8d. 08h., Mercury 4·3° S., and Venus is in conjunction with Saturn on Oct. 30d. 22h., Venus 2° S. Mercury is too close to the Sun during the greater part of October for observation, but towards the end of the month it rises about an hour and a half before sunrise and is visible for a short time in the eastern sky. Venus sets shortly after the Sun during the month and is not favourably placed for observation. Mars rises about 4h. 30m. throughout October and is visible in the constellation Leo in the early part of the month, moving later into Virgo, and is close to $\eta$ Virginis about October 19 and to $\gamma$ Virginis about October 28, its stellar magnitude remaining 2·0 during this time. Jupiter rises at 1h. 50m., 1h. 10m. and 0h. 20m. on October 1, 15 and 31, respectively. Its eastward movement in Leo is easily seen, and towards the end of the month it is very close to $\alpha$ Leonis. Its stellar magnitude varies from − 1·4 to − 1·5 owing to its distance from the Earth decreasing from 558 to 522 million miles during the month. Saturn sets at 19h. 10m., 18h. 15m. and 17h. 20m. on October 1, 15 and 31, respectively. Its eastward movement can be detected by noticing that it approaches $\gamma$ Librae during the month. Its stellar magnitude remains 0·8, although its distance from the Earth increases from 991 to 1,013 million miles during October. The Orionid meteor shower attains a maximum during October 20–23; the radiant at R.A. 6h. 24m., Dec. 15° N., near the north-east of the constellation Orion, is close to $\gamma$ Geminorum.

## Announcements

THE ninth Eddington Memorial Lecture will be given by Prof. R. B. Braithwaite, of King's College, Cambridge, on November 22, at 5.15 p.m., in Oxford. He will speak on "An Empiricist's View of the Nature of Religious Belief".

DR. W. B. LITTLER has been promoted to a chief scientific officer and appointed principal director of scientific research (defence), Ministry of Supply, in succession to Dr. W. Cawood, who is to become principal director of scientific research (air) on November 1.

DR. W. STEVEN has been appointed superintendent of the Development and Research Department Laboratory of the Mond Nickel Company, Ltd., Birmingham, in succession to the late Mr. Howard Evans. Dr. Steven, who is a graduate of the University of Glasgow, was for five years engaged in research and works control on tool steels, constructional steels and stainless steels at Wm. Jessop and Sons, Ltd., Sheffield. Then in July 1947 he joined the Mond Nickel Company, where he has been working on alloy steels and cast irons, particularly on transformation in steels and problems associated with spheroidal-graphite cast iron. He was at one time secretary of the Hardenability Sub-Committee of the Ministry of Supply Special and Alloy Steels Committee.

MR. F. S. O. BROUGHTON, assistant secretary of the Development Commission, has been appointed to succeed Mr. E. H. E. Havelock as secretary of the Commission. Mr. Havelock will continue to serve the Commission for a further period as secretary to a committee appointed to inquire into and advise upon the future organization of fishery research.

THE Science Museum, London, is showing for about six months a special exhibition on the evolution of the dividing machine. Until the middle of the eighteenth century, measuring scales of scientific and other instruments were divided by hand or by the use of a dividing plate, but in 1775 Jesse Ramsden built a successful dividing engine which divided circular scales mechanically. Since his time progress has been in the direction of automatic operation of the machines and increased accuracy of their work. The eight circular dividing machines to be shown range in date from 1778 to 1955, and two of them will be shown in operation.

DR. GABRIEL KRON will deliver three lectures at the Imperial College of Science and Technology, London, on the "Method of Tearing" on October 7 and 8. He will discuss a technique for the numerical and analytical solution of complex physical systems such as large electrical networks and large mechanical structures. Further particulars can be obtained from the Deputy Registrar, City and Guilds College, Imperial College, London, S.W.7.

THE annual reports for 1954 of the British Rubber Development Board and of Rubber Technical Developments, Ltd. (pp. 47 and 15, respectively; from the Board at Market Buildings, Mark Lane, London, E.C.3), refer to progress in the development of unwoven fabrics bonded with rubber deposited from latex, the use of rubber in roadmaking, rubber rail pads (inserted between rail and sleeper), and the use of latex foam in furniture.

THE Electron Microscopy Group of the Institute of Physics is arranging a conference on "The Electron Microscopy of Textile and Other Industrial Fibres", to be held in the University of Leeds during January 3–4. The main groups of topics it is hoped to discuss are specimen techniques, the fine structure of cellulose, synthetic and protein fibres and the surface properties of fibres. Correspondence relating to the conference should be addressed to Dr. J. Sikorski, Textile Physics Laboratory, University, Leeds 2, and sent to him as soon as possible.

IN *Nature* of September 17, p. 526, there was a review of "Michael Tswett's First Paper on Chromatography", issued by M. Woelm, of Eschwege. L. Light and Co., Ltd., Poyle Estate, Colnbrook, Bucks, are the British agents for M. Woelm for the sale of their activated alumina for chromatography, and they have a few copies of the brochure; it is free of charge.

# MAN AND HIS MACHINES

SECTION L (Education) of the British Association organized on the afternoon of September 2 a symposium on the automatic age under the title of "Man and his Machines". Three papers were presented before an audience of 350–400 in the following order: (1) "New Concepts of Science and Advanced Industrial Techniques", by Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research; (2) "The Training of Technicians for the Automatic Age", by Dr. J. E. Richardson, principal, Northampton Polytechnic, London; (3) "Automation and Education", by Mr. H. A. Rée, headmaster of Watford Grammar School.

Sir Ben Lockspeiser said that automation has come along because fundamentally "People turn to machines to save themselves trouble, and as few want to do more arithmetic than they must, they have always been on the lookout for devices to make arithmetic easier". He surveyed the development of computers from the days of Charles Babbage to the elaborate electronic machines of to-day which have been given the label of 'electronic brains'. He sees some justification for the label though it can be misleading, and spoke of their very reliable memories, built-in facilities of judgment and fantastic speeds. The applications of these machines are far-reaching in their consequences and already include: passenger reservations at La Guardia Airport, New York; mail-order business in an American firm, where with its aid ten clerks handle 80,000 orders a day covering 12,000 different items; commercial operations at Messrs. J. Lyons and Co., Ltd., in preparing the pay-roll for 10,000 employees as well as a large variety of other requirements.

Sir Ben foresees an end to the vast and otherwise increasing volume of paper-work which has been the bane of large business houses; in its place will come the automatic routing of information, resulting in the replacement of intelligent guessing by exact information, and the bringing in of efficiency in direction and economy of practice.

Turning from computers to production, Sir Ben sees the counterpart of the automatic control of fluids in the oil, chemical and food industries in the new handling machines for transferring work from one operation to another. These techniques, introduced by Morris Motors so far back as 1923, have now been developed considerably, not only in the United States but also in Britain and on the Continent, especially in connexion with the automobile industry.

As a digression, it may be mentioned that on the previous day, Mr. Alec Rodger, of Birkbeck College, London, had told Section J (Psychology) that in a Moscow factory making pistons for the whole of the Russian light-car industry, only nine men were employed per shift.

Sir Ben concluded by saying that the fruits of fully automatic production will only be gathered by a population substantially upgraded in skill and intellect. There would be a need for many more scientists and technologists than are available at present. In Great Britain, this involves a sufficient number of good-quality teachers of mathematics and science for the schools of the country.

Dr. Richardson's paper covered the much narrower field of the resources of the technical colleges of Britain to cope with the training of technicians for the automatic age. He sounded a note of optimism based on the following factors:

(1) Automation is neither new nor sudden in its appearance.

(2) The first industrial revolution saw both mechanization and automation (for example, mule spinning and jacquard weaving) without the aid of technical colleges as we now know them. The second industrial revolution, as some are naming the present phase, will, however, be served by a nation-wide system of colleges second to none in any other country.

(3) The present numbers of B.Sc. degrees, Higher National Certificates and City and Guilds of London Institute certificates gained in the technical colleges of Britain are most impressive. Of perhaps even greater significance in the present context is the large number and variety of short courses in advanced studies designed to take well-qualified men to higher levels of study in subjects already covered, or into new subjects not previously studied. Many of these subjects are concerned with electronics, computers, automatic process control, servo-mechanisms, and the like.

On the question of the numbers of technicians required, Dr. Richardson believes that they will preponderate over other grades of employee, but he does not think the total numbers will be alarmingly great. If automation were to reduce the number of workers needed as drastically as many claim, the total numbers could scarcely increase. The electrical industry, it is said, uses personnel in the ratio of 1 : 5 : 8 for professional engineers, technicians and craftsmen respectively. Dr. Richardson hazarded the opinion that the ratio might become 1 : 3 : 2.

Despite the reasonably satisfactory state of affairs in the technical colleges of Britain, Dr. Richardson mentioned six essential requirements for the changing emphasis brought in by automation. These are: large laboratories for pilot plant; smaller laboratories adequately equipped with the latest gadgets; closer integration with industry in the planning and running of courses; generous financial provision which would take as normal a piece of equipment costing £25,000 such as the computer he hopes to instal in the Northampton Polytechnic in the near future; abolition of restrictive practices by boundary-conscious local education authorities; adequate salary scales for staffs.

Mr. Harry Rée's contribution was entirely different from the preceding in that philosophical and humanistic considerations replaced scientific and technical factors. Dealing with the contribution of the schools, he wondered in the first place where all the extra technicians are to come from. From the grammar and public schools, he said, they can only come by decreasing the number of arts students. From the modern secondary schools, in which are to be found some 80 per cent of the nation's children, only a mere trickle can be expected of those capable of reaching graduate or Higher National Certificate level. Maybe on the short-term issue, British parents had anticipated the need by the increased birth-rate in early 1940's.

After expressing the fear that technical colleges are not educational institutions but teaching shops, he emphasized that "in building a world where machines do the work which used to be done by men, it is not good enough to build men who can only work like machines. It is not enough to produce managers who know *how* to increase production; of far greater importance is it to produce managers who know *why* they should increase production, or even *whether* they should".

To the recognized "deeply humanizing, deep moral importance of liberal studies", Mr. Rée added the less recognized importance of planned and wisely used leisure. He warned that "To an ever increasing extent we have handed over the organization of our spare time to those who can make money out of us, to the purveyors of entertainment, to those who can offer us diversion without exertion, and hour after hour we are content to watch, to listen and to consume".

He concluded by envisaging the great contribution educational institutions could make by a counter attack on the creeping disease of passive pleasures which is eating away the soul of modern man. "If we could make the effort, all these things (commercial entertainment, ostentatious expenditure, slot machines and cinemascopes) could be swept away and we should look upon automatic factories and computing machines as our benefactors enabling us and our children to taste to the full the real joys of life."

In the discussion which followed, the suggestion was made that we may have to look to women to swell the force of technicians. Sir Ben Lockspeiser disagreed with Dr. Richardson's complacency on numbers; he emphasized that every technical industry, including government departments, is crying out increasingly for more and more technicians. He concluded by warning his audience that automation is not before us as a choice—it is a sheer necessity. Without automation we cannot increase production, without increased production we cannot remain competitive, without trade we shall perish.

J. E. RICHARDSON

# THIRD INTERNATIONAL CONGRESS OF BIOCHEMISTRY

THE Third International Congress of Biochemistry was held in Brussels during August 1–6, under the presidency of Prof. E. J. Bigwood, and was attended by more than seventeen hundred delegates from all parts of the world. The official opening on August 1 was followed by the inaugural lecture, given at the Palais des Beaux-Arts by C. Martius, of Würtzburg, his subject being "Thyroxin und oxidative Phosphorylierung". On the evening of the same day the official reception was held at the Musées Royaux d'Art et d'Histoire du Cinquantenaire, and was preceded by a tour of the exhibits.

Besides the opening and closing lectures, formal lectures were given by P. S. Sarma (India) on biochemical aspects of *Corcyra* nutrition; R. H. S. Thompson (Great Britain) on biochemical disorders in peripheral neuritis; N. M. Sissakian (U.S.S.R.) on biochemical properties of plastids; P. H. Bell and R. G. Shepherd (United States) on purification and structure of β-corticotrophin and its active degradation products; P. Grabar (France) on the study of mixtures of proteins by electrophoretic and immunoelectrophoretic analysis in gels; and L. Seekles (Holland) on the role of the trace elements in nutrition. F. B. Straub (Hungary), who was also due to speak, was unable to attend.

The remainder of the scientific programme was divided into two classes of communications which were concurrent. These were, first, report sessions, which consisted of reviews given by workers in the various fields, and which were followed by prepared discussions by invited speakers who had been provided with advance copies of the talks; and, secondly, the scientific communications proper, which were short papers dealing with recent research.

The reports, most of which were printed and circulated to members of the Congress beforehand in the form of a most useful booklet, covered a wide field ranging from pure chemistry, on one hand, to pure biology on the other. The subjects discussed included the biosynthesis of peptides (H. Borsook), photosynthesis (M. Calvin), transmethylation (G. L. Cantoni), formation of organic acids in moulds (E. B. Chain), growth stimulation by antibiotics (M. E. Coates and S. K. Kon), antibiotic polypeptides (L. C. Craig), proteolytic enzymes (P. Desnuelle and M. Rovery), hexose monophosphate oxidation (F. Dickens), physical chemistry of deoxyribonucleic acid (P. Doty and N. Simmons; C. Sadron), structure of polypeptides and proteins (A. Elliot), genetic function of deoxyribonucleic acid (H. Ephrussi-Taylor; O. Maaloe), incorporation of amino-acids in the presence of ribonucleic acid fragments (E. F. Gale), amino-aciduria (H. Harris), effects of ionizing radiation (G. Hevesy and A. Forssberg), antimetabolites related to purines (G. H. Hitchings and G. B. Elion), mucopolysaccharides (R. W. Jeanloz), carbamyl phosphate (M. E. Jones, L. Spector and F. Lipmann), energetic coupling (H. Lardy), uridine coenzymes (L. F. Leloir), metalloflavoproteins (H. R. Mahler), ribonucleic acids (R. Markham), determination of steroids (G. F. Marrian), biochemistry of the nucleus (A. E. Mirsky), brain biochemistry (A. V. Palladine; A. J. Rosenberg), skeletal muscle metabolism (S. V. Perry), antibiotics and intestinal flora (L. Y. Quinn), biochemistry of anæsthesia (J. H. Quastel), aseptic breeding of rats (J. Reyniers), bacterial cell structure (M. R. J. Salton), cell structure and metabolism (W. C. Schneider), porphyrin biosynthesis (D. Shemin), respiratory chain phosphorylation (E. C. Slater), respiratory adaptation (P. Slonimski), enzymic adaptation (S. Spiegelman), antibiotics and nutrition (E. L. R. Stokstad), hormonal regulatory mechanisms (E. W. Sutherland), ion transport (H. H. Ussing and B. Andersen), nitrogen fixation (A. I. Virtanen), muscle and cell contraction (H. H. Weber) and the chemistry of nerve activity (I. B. Wilson).

The original communications, which numbered more than eight hundred in all, were given in seventeen sections: organic chemistry of substances of biological interest; chemistry and physical chemistry of proteins and polypeptides; chemistry and physical chemistry of nucleoproteins and nucleic acids; enzymology; intermediary metabolism; cellular oxidation and oxidative phosphorylation; biochemical regulation; cellular biochemistry; biochemistry of muscle and the central nervous system; chemical microbiology; plant and soil biochemistry; zoological chemistry; nutrition; pathological chemistry and immunochemistry; pharmacological chemistry; clinical chemistry; and industrial biochemistry. Such a division into sections is somewhat arbitrary and, consequently, related papers were to be found in several different sections. A gallant and partly successful attempt to overcome this deficiency was made by the organizers, who provided the delegates with a timetable for each day and who enforced a most rigid control over the time taken by each speaker. However, on occasion, as many as twenty choices were afforded at any one time, in as many different places, and it is unlikely that anyone managed to attend all the papers which he wished to hear.

An excellent item of organization, and one which can be recommended to organizers of future congresses of this size, was the provision of ample space for informal meetings between delegates, both at the Congress headquarters at the University of Brussels and in the adjacent Cité Universitaire, where all manner of facilities were provided.

In addition to the opening reception a number of social activities were arranged, the main one being a concert given by the Belgian National Orchestra at the Palais des Beaux-Arts. There was no formal Congress banquet, but some informal sectional dinners were given, and the International Association of Clinical Chemistry arranged a banquet open to all members of the Congress. Both the Russian and the Polish delegations gave receptions at their respective embassies, and these were attended by guests from both sides of the Atlantic. An exhibition of scientific equipment was given at the Congress headquarters, and a number of British scientific equipment manufacturers were represented. The closing lecture was given by V. du Vigneaud (New York) on the isolation and proof of structure of the vasopressins and the synthesis of octapeptide amides with pressor-antidiuretic activity.

The next Congress will be held in Vienna in 1958.

# RADIATIVE BALANCE IN THE ATMOSPHERE

## ROYAL SOCIETY DISCUSSION

It is appropriate, in view of the forthcoming intensification of atmospheric research during the International Geophysical Year of 1957–58, to examine the present state of research in such a subject as radiative balance in the atmosphere, and a one-day discussion meeting on this subject was held in London at the Royal Society on June 9. In such a short period it was clearly out of the question to attempt any comprehensive survey, and attention was concentrated instead on subjects in which research is being actively pursued. Many of those who took part are contributors to the Gassiot Committee programme of research on photochemical equilibrium in the atmosphere. Two invited speakers from abroad, Dr. F. Möller (University of Mainz) and Dr. M. V. Migeotte (Institut d'Astrophysique, Liège), made interesting contributions. The programme was arranged so that the morning and early afternoon were mainly devoted to the lower atmosphere, up to and including the stratosphere, and the late afternoon to the higher levels of the atmosphere.

The discussion was introduced by Prof. H. S. W. Massey (University College, London), who first outlined the general nature of the radiation balance in the atmosphere and indicated the importance of the different absorption, emission and scattering processes which are involved. The second part of his talk was concerned with the temperature and pressure distribution in the atmosphere. These may be directly studied up to altitudes of 150 km. by means of instruments transported by rockets. Methods of measurement of pressure, temperature and density were outlined, and the interrelation of these three quantities was pointed out as a useful check on the results obtained. Special attention was directed by Prof. Massey to the way in which the rocket observations of pressure, taken above White Sands, New Mexico, agree well with results obtained by balloon flights up to altitudes of 24 km. The importance of further rocket measurements in different geographical locations was stressed.

Dr. Moller next discussed the pattern of radiative heating and cooling in the troposphere and lower stratosphere. After describing the distribution of temperature and of the cooling-rate by water vapour in some characteristic atmospheres at different latitudes, he directed attention to systematic differences from this characteristic behaviour which have been observed in the last year. These differences he ascribes to the effect of cloud layers, and the remainder of his contribution was concerned with these effects. Statistical studies of the frequency and thickness of clouds over Germany during the period 1930–40 are now proceeding at the Meteorologisch-Geophysikalisches Institut at Mainz, these being based on the observations of the Wetterflugstellen. Using these data, radiation fluxes and mean cooling water characteristics of cyclonic warm air have been computed and show that at every height the cooling is slightly increased by the cloud. Further work on these lines is proceeding.

Dr. A. R. Curtis (University of Sheffield) described the elaborate computations which he is carrying out on radiative heating-rates in the atmosphere. The starting-point is the derivation from the equation of radiative transfer of an expression for the rate of heating at any height in a plane-stratified atmosphere due to interaction of molecules of a single absorbing constituent with radiation. Even in this simplified case the expression is quite formidable. Knowledge of line frequencies and intensities and of line shape as a function of height is required. To make the calculations tractable, it is assumed that the line intensities are distributed according to a probability function. Approximate calculations for the 15-$\mu$ carbon dioxide band have been made, but further work will be carried out using electronic computation.

Dr. Migeotte described the results of high-resolution spectroscopic investigation of minor atmospheric constituents—ozone, nitrous oxide, methane, monodeuterated water and carbon monoxide. Several bands, as they appeared on solar spectrograms taken at the International Scientific Station on the Jungfraujoch at an altitude of 3,850 m., were shown; they were obtained using the prism-grating infra-red spectrograph of the University of Liège. Attention was directed by Dr. Migeotte to the presence of the 9-$\mu$ band of ozone and the 17-$\mu$ band of nitrous oxide in the solar spectrum. An atlas of the solar spectrum containing reproductions of the Jungfraujoch records is now ready for publication.

The afternoon session of the meeting began with a discussion by Dr. G. D. Robinson (Kew Observatory) of the scope of observations of solar and terrestrial radiation at the earth's surface. This included a critical survey of recent measurements of quantities important in determining the radiative balance at the latitude of Kew. In addition, Dr. Robinson discussed the contribution that can be made to the solution of the meteorological problem by the programme of measurements proposed for the International Geophysical Year. He concluded that, although these measurements must of necessity be limited for economic reasons, useful results can be obtained with existing equipment. The importance, both during and after the International Geophysical Year, of observations on solar radiation at a high level, such as those made by the Meteorological Research Flight, was stressed. He also said that, in order that separate estimates of albedo in the infra-red and visible plus ultra-violet can be made, as many stations as possible should make measurements of solar radiation in the infra-red.

Three papers followed on the important subject of the use of high-altitude aircraft as laboratories from which measurements of radiant intensities and infra-red spectroscopic studies can be made. The opening paper was by Dr. F. E. Jones (Royal Aircraft Establishment, Farnborough), who described the design of an infra-red spectrometer for use in a Canberra aircraft, with which it is hoped to record the solar spectrum out into the far infra-red from heights up to 50,000 ft. Initial measurements from a Lincoln aircraft at 30,000 ft. have permitted observation of the $\nu_3$ band of methane (this being the first observation of methane as a constituent of the atmosphere over England) and the complete nitrous oxide doublet at 4·5 μ. Next, Dr. J. Yarnell (de Havilland Propeller Co.) gave an account of the promising experiments undertaken in collaboration with Dr. R. M. Goody with an aircraft of the Meteorological Office Research Flight. Although these experiments did not lead ultimately to definite results, they were of interest and importance in providing design data and experience for the work which is now projected. The final paper on this subject was read by Dr. J. Houghton (University of Oxford), who described work carried out with Dr. A. W. Brewer on the measurement of the water vapour and ozone in the troposphere and lower stratosphere from aircraft. The technique used has proved successful in obtaining important results over Britain. At the time of the discussion, Dr. Brewer was in Norway carrying out similar measurements with the collaboration of the Norwegian Air Force; this work has also proved very successful.

The origin and distribution of the polyatomic gases in the atmosphere was next discussed by Prof. G. M. B. Dobson (University of Oxford), special attention being paid to water vapour and ozone. The water vapour concentration usually decreases rapidly with increasing height, particularly in the lower stratosphere, and this leads to a very low concentration at an altitude of about 15 km. Ozone, on the other hand, has a maximum concentration at an altitude of about 30 km. and diffuses downwards. Data were presented on the water vapour content of the lower stratosphere and on the average values of the ozone/air ratio in the upper troposphere and lower stratosphere (obtained largely from flights over southern England by the Meteorological Office Research Flight). The difficulties encountered in attempting to interpret these results were pointed out.

The next paper to be presented, by Dr. R. M. Goody (Imperial College of Science and Technology, London), was an account of work carried out with Dr. A. R. Curtis on thermal equilibrium in the upper atmosphere. Dr. Goody pointed out that the assumption of a Boltzmann distribution of molecules among the vibrational and rotational levels, which is usually assumed in atmospheric radiation calculations, must break down at sufficiently high altitudes when the pressure is inadequate to maintain a sufficiently high collision-rate. An equation of transfer was derived for a vibration-rotation band which does not assume a Boltzmann distribution among the vibrational levels. From this in turn was derived an equation for the heating-rate due to the band in a plane-stratified atmosphere. Departure from a Boltzmann distribution becomes serious above about 75 km. For the rotational levels the effect is unimportant for vibration-rotation bands, but it limits computation in the rotation bands of water vapour to heights less than about 90 km.

The temperature distribution at higher altitudes (200 km. and above) was the subject of a paper by Prof. D. R. Bates (The Queen's University, Belfast), which was concerned primarily with the importance of thermal conductivity in relation to the temperature distribution at these high altitudes. Prof. Bates argued that the temperature gradient, instead of remaining almost constant up to great altitudes, as commonly assumed, must fall off above the base of the $F_1$-layer. Rocket and radio measurements suggest that the temperature near the 250-km. level is only about 800° K.; and the usual theory of the apparent escape of atmospheric helium into interplanetary space requires that the temperature in the exosphere is at least 1,500° K. According to Prof. Bates, the temperature rise of about 700 deg. K. that is thus indicated is an order of magnitude greater than can be accepted. It would necessitate that the local rate of gain of thermal energy by absorption at the 250-km. level be some $10^4$ eV./cm.$^3$ sec. Little plausibility can be attached to the existence of such a potent heat source.

The important new data now being obtained in the solar spectrum in wave-length regions previously unobservable because of atmospheric absorption were described by Dr. R. L. F. Boyd (University College, London). The results have been obtained in the United States using apparatus carried by rockets to altitudes greater than 100 km. A variety of techniques have been used employing photon counters, photographic plates, thermoluminescent phosphors and spectrographs as observing devices. More than forty flights have been made. At the height of the $E$-layer, solar X-radiation has been detected, of sufficient intensity to produce the $E$-layer ionization. Lyman α-radiation concentrated in a narrow line has been observed down to altitudes of 74 km. It has also been found that the intensity of the solar spectrum falls off in the ultra-violet at a faster rate than for a black body at 6,000° K.; thus at 2000 A. the intensity corresponds more nearly to that from a black body at 4500° K. The importance of these results was discussed.

The concluding paper was given by Prof. R. W. Ditchburn (University of Reading) on the absorption of ultra-violet radiation by the atmospheric gases. He discussed the order of magnitude of the absorption coefficients for photoionization and photodissociation continua and their relation to absorption lines and bands. A summary was given of measurements and calculations on nitrogen, or molecular and atomic nitrogen and oxygen and ozone. Using these data and the model atmosphere assumed by the United States Rocket Panel on the basis of its observations, effective depths of penetration of radiation into the atmosphere were obtained. Data available on the absorption by minor atmospheric constituents were also presented in tabular form.

# CHEMISTRY OF NATURALLY OCCURRING PYRONES

## SYMPOSIUM IN DUBLIN

A SYMPOSIUM on recent advances in the "Chemistry of Naturally Occurring Pyrones" was held in the Department of Chemistry, University College, Dublin, during July 12–14. The symposium was organized by the College and the Institute of Chemistry of Ireland to mark the fortieth anniversary of the first paper on flavones published by Prof. Hugh Ryan, who was professor of chemistry in University College during 1899–1931. This branch of chemistry has been systematically studied in Dublin since 1915, and a number of useful syntheses of flavonoids have been devised. The meeting was opened by Prof. T. S. Wheeler on behalf of Dr. Michael Tierney, president of University College, Dublin. Some one hundred and thirty chemists from twelve countries took part in the proceedings.

Prof. W. Cocker (Trinity College, Dublin) was chairman of the first of five half-day sessions. Prof. J. Algar (University College, Dublin) gave a brief account of the researches of Prof. Hugh Ryan. He was followed by Prof. Gertrud Woker (University of Berne), who assessed the pioneering work of Kostanecki in the flavone field.

Prof. T. R. Seshadri (University of Delhi) reported some new results on the occurrence of chalkones and flavanones in plant products. The presence of a 5-hydroxyl group in flavanones makes the structure so stable that the corresponding chalkones do not occur in the plant. This effect is attributable to chelation. Detailed work on the flowers of *Butea frondosa*, on the bark of *Prunus puddum*, and on carthamin, the pigment of the safflower, was described.

Prof. F. E. King (University of Nottingham) discussed the constitution and synthesis of leucoanthocyanidins. The identification of melacacidin (from *Acacia melanoxylon*) as 7 : 8 : 3′ : 4′-tetrahydroxyflavan-3 : 4-diol and the nature of the products obtained from its treatment with hot mineral acid afford conclusive evidence that the flavan-3 : 4-diol structure is typical of the majority of the ill-defined natural products known collectively as leucoanthocyanidins. The (±)-tetramethoxyflavandiol—one of four theoretically possible racemates—which is formed by the catalytic reduction of 7 : 8 : 3′ : 4′-tetramethoxyflavonol is believed to be *dl-O*-tetramethylmelacacidin. The probable conformational structure of this product was discussed.

In the second session, over which Dr. V. C. Barry (Medical Research Council of Ireland) presided, Prof. K. Venkataraman (University of Bombay) gave an account of some naturally occurring γ-pyrone derivatives. He discussed the synthesis of muningin (6 : 4′-dihydroxy-5 : 7-dimethoxy*iso*flavone). Pinoquercetin and pinomyricetin, which occur in *Ponderosa* pine bark, have been shown to be, respectively, 6-methylquercetin and 6-methylmyricetin. The structure of a new, yellow, colouring matter (artocarpin) from the heartwood of *Artocarpus integrifolia* and of morellin (from the seeds of *Garcinia morella*) were discussed.

Dr. W. B. Whalley (University of Liverpool) suggested that the abnormal resinification of 2′-methoxy*iso*flavones when demethylated by hydriodic and hydrobromic acids (Whalley, *J. Amer. Chem. Soc.*, 75, 1059 ; 1953 ; and Baker *et al.*, *J. Chem. Soc.*, 1853 ; 1953) could be explained by postulating a rearrangement of 2′-hydroxy*iso*flavones to the acid-sensitive 2-unsubstituted-3-aroylbenzofurans, under the influence of the demethylating reagent. A series of such 3-aroylbenzofurans has now been synthesized and the properties, including various transformation reactions, examined. Several other potential routes to these benzofurans have been explored. It has been found that 2′-hydroxydeoxybenzoins (prepared from *iso*flavones) undergo spontaneous cyclization to the corresponding 2-arylbenzofurans. Cognate reactions were discussed in the light of these and other transformations.

Dr. T. H. Simpson (Torry Research Station, Aberdeen) spoke on the use of *iso*propyl groups for protection of phenolic hydroxyl groups in the synthesis of flavones by selenium oxidation of the appropriate chalkones. The use of the *iso*propyl group permits the synthesis of compounds such as acacetin, diosmetin, chrysoeriol, oroxylin-A, pectolinearigenin, in excellent yield.

The second morning session (chairman, Prof. P. O'Colla, University College, Galway) was opened by Prof. Wilson Baker (University of Bristol), who outlined recent developments in the synthesis of *iso*flavones. A method evolved in Bristol in recent years employs the reaction of 2-hydroxydeoxybenzoins with ethoxalyl chloride in pyridine to yield 2-carbethoxy*iso*flavones. Mild alkaline hydrolysis of these esters, followed by thermal decarboxylation of the resulting acids, gives *iso*flavones. Good yields are obtained and it is unnecessary to protect hydroxyl groups.

Prof. H. Erdtman (Royal Institute of Technology, Stockholm) described studies on the flavones and flavanones present in the heartwood of conifers, especially the genus *Pinus*. These studies were undertaken as part of a systematic investigation of the conifer group to obtain chemical evidence relating to the phylogeny of the class Coniferae. About 75–80 per cent of the pines have been examined by preparative or chromatographic methods, and ten flavonoids and three stilbenes have been isolated. These compounds have one unsubstituted phenyl nucleus, so that it is possible that these nuclei are ontogenetically identical. The botanical subdivision of the genus *Pinus* into two sections, *Diploxylon* and *Haploxylon*, is favoured by the chemical results. Flavone derivatives have also been isolated from the heartwood of some conifers botanically related to the pines. Together with other chemical evidence, the flavone derivatives provide useful indications of taxonomic relations between various conifers, especially those belonging to the natural order *Pinales*. In other orders other compounds appear to be equally significant as 'taxonomic tracers'. Examples are terpenic and tropolonoid constituents in the natural order *Cupressales*.

Prof. S. Hattori (University of Tokyo) spoke on the seasonal changes of flavone and flavanone glycosides in the leaves and fruits of *Poncirus trifoliata*. The leaves in the middle of May when in full development contain approximately equal quantities of poncirin (7-rhamnoglucoside of 5 : 7-dihydroxy-4′-methoxyflavanone) and rhoifolin (7-rhamnoglucoside of 5 : 7 : 4′-trihydroxyflavone). At the end of the month only a small quantity of poncirin remains. Poncirin predominates in the middle of April when the leaves are just developed from the buds. The percentage of poncirin in the fruits falls during the summer and autumn.

The fourth session, which was held on the morning of July 14, had Dr. R. G. R. Bacon (The Queen's

University, Belfast) as chairman. Prof. H. Schmid (University of Zurich) surveyed the components of *Ammi visnaga*. He discussed the chemistry of visamminol, a chromone present in the plant. The structure of athamantine, which is present in *Athamanta oreoselinium* L., and which is related to compounds in *Ammi visnaga*, was described. Prof. Schmid also spoke on other compounds from tropical plants.

Prof. K. Freudenberg (University of Heidelberg) gave an address on catechins and related compounds. The number of known catechins has been enlarged, by syntheses, and by the discovery of new naturally occurring members of the series. The explanation of the sensitivity of catechins towards acids lies in the presence of hydroxyl groups in both the 4′- and 7- positions. The possibility of acid polymerization was discussed, as was the relation of catechins to the phlobatannins and to the flavylium salts.

Dr. W. D. Ollis (University of Bristol) described work relating to the synthesis of diploicin. This compound is a member of the group of natural products termed depsidones and, as yet, no synthesis of a member of this group has been reported. Depsidones may be regarded as lactones derived from various 2-carboxy-2′-hydroxydiphenyl ethers, and the dehydration of this acid and related acids was discussed. An interesting feature of these reactions is an effect of hydrogen bonding which promotes intermolecular reaction and inhibits intramolecular reaction. This intermolecular reaction leads to certain macrocyclic compounds the formation of which is facilitated by the presence of rigid assemblies of atoms in the reactant molecules. The synthesis of depsidone and progress towards the synthesis of diploicin were discussed.

Prof. Joseph Algar (University College, Dublin) was chairman of the final session, which was held on the afternoon of July 14. Dr. E. C. Bate-Smith (Low Temperature Laboratory, Cambridge) discussed the chromatographic identification of phenolic constituents of plants and their systematic distribution. Phenolic substances occur in living plant cells almost exclusively in the form of glycosides or esters. As a first step in the recognition of these compounds, it is necessary to ascertain the nature of the phenolic residues. Practically every commonly occurring phenolic residue can be recognized by chromatography employing four or five solvent systems. Using such procedures, a systematic survey is being made of the phenolic constituents of the leaves of vascular plants. Particular phenolic compounds tend to be associated with particular systematic groups, and a number of such associations was discussed.

Dr. R. G. R. Bacon (The Queen's University, Belfast) reported the results of investigations on the Elbs persulphate reaction, which has been widely used in the preparation of hydroxyflavones. He presented data for the process to illustrate the effects of varying the nature and the relative proportions of the reactants. Reaction-rates were discussed and examples were given of the competition which occurs in the reaction between the desired effect, namely, nuclear sulphation, and other modes of oxidation.

Prof. T. S. Wheeler (University College, Dublin) described studies in the synthesis of γ-pyrones. For many years the Auwers method of synthesizing flavonols from aurone dibromides provided the only known example of ring expansion of an aurone to a flavone derivative. Recently two further methods of effecting this ring enlargement have been developed in Dublin. Treatment of certain aurones with ethanolic potassium cyanide gives the corresponding flavones. Oxidative ring enlargement of aurones to flavonols is obtained with hydrogen peroxide. This latter reaction was independently observed by Prof. T. A. Geissman, of the University of California, Los Angeles. A new synthesis of flavonols involving the action of an aromatic aldehyde on an ω-chloro-*o*-hydroxyacetophenone was discussed.

At an evening meeting during the symposium, under the chairmanship of Prof. T. Dillon, president of the Institute of Chemistry of Ireland, Dr. W. D. Ollis lectured on the total synthesis of strychnine. He described this recent achievement of the Harvard group, who worked under the direction of Prof. R. B. Woodward, and of which Dr. Ollis was a member. During the symposium receptions were given by Their Excellencies the President of Ireland and Mrs. O'Kelly, and by the President of University College, Dublin, and Mrs. Tierney. A successful symposium dinner was also held.

This symposium was probably the first to be devoted mainly to the chemistry of flavonoids and related compounds. The papers and discussions covered both the chemical and biochemical sections of the subject and showed the increasing interest which since the War has been taken in this field of chemistry. The development of the method of paper chromatography has greatly increased our knowledge of the occurrence of these substances in plants. Apart from their importance as natural products, flavonoids are of therapeutic interest. They are effective in treating capillary fragility and may have value in rheumatic fever and poliomyelitis. They are, of course, no longer used as dyestuffs.

T. S. WHEELER

---

# AMERICAN PHYSICAL SOCIETY AND AMERICAN ASSOCIATION OF PHYSICS TEACHERS

## ANNUAL MEETINGS

THE 1955 annual meeting of the American Physical Society and the twenty-fourth annual meeting of the American Association of Physics Teachers were held simultaneously in New York City, during January 27–29, but not, as formerly, in the buildings of Columbia University. The various scientific sessions of the Society's meeting were distributed over several centres, including the Hotel New Yorker, the Hotel McAlpin, the Manhattan Center and the Vanderbilt Hall of New York University. Not all of the halls proved adequate; nevertheless the regrettable but inevitable dispersal was not, on the whole, unsatisfactory. The registration for the meetings was 1,987, about 5 per cent less than for the 1954 meetings, but the number of contributed papers presented to the Physical Society was about 10 per cent higher.

At the joint ceremonial session of the two bodies during January 28 in the great theatre of the Manhattan Center, the retiring presidential address of the Physical Society was delivered by Prof. H. A. Bethe (Cornell University), who took as his subject "Pi-Mesons and Nucleons"; the Oersted Medal of the Association was presented to Prof. V. E. Eaton (Wesleyan University), who responded by discussing physics as an art; and the thirteenth Richtmyer Memorial Lecture was delivered by Prof. E. P. Wigner (Princeton University), who spoke on "The

Development of the Compound-nucleus Model". The after-dinner speakers at the joint banquet which followed, held in the ballroom of the Hotel New Yorker, were Prof. H. D. Smyth, and Mr. G. Bell, who gave an interesting description, illustrated by a film, of the 1954 expedition up the Himalayan peak, K-2. The banquet was also the occasion of the presentation of the third O. E. Buckley Solid-State Physics Prize to Dr. LeRoy Apker.

Twenty-four invited papers, in addition to the three hundred and thirty ten-minute papers, were contributed to the scientific sessions of the Physical Society. There were also two symposia: one of the Division of Fluid Dynamics, on fluid-dynamics problems in astrophysics; and the other of the Division of Electron Physics, in which three papers were read by R. E. Fox, M. G. Inghram and J. Kaplan, respectively, on measurements of ionization probabilities of mono-energetic electrons, mass-spectrometric analysis of ions produced in the field ion microscope, and upper-atmospheric studies during the International Geophysical Year. A group of four invited papers was devoted to hyperons and heavy mesons, in which investigations of the Bristol (England), Indian and Italian schools were described by M. G. K. Menon (University of Bristol), Y. Pal (Tata Research Institute, Bombay) and N. Dallaporta (University of Padua), respectively; and E. O. Salant (Brookhaven National Laboratory) discussed heavy mesons produced in the interactions of 2–3 BeV. particles. There were two papers on nuclear polarization, given by E. Segrè (University of California) and B. Rose (Atomic Energy Research Establishment, Harwell), and three papers on nuclear instrumentation, including one by D. A. Glaser (University of Michigan) on bubble chambers for use in experiments in high-energy nuclear physics. Papers on nuclear physics predominated, but there were sessions devoted also to discharges and ions in gases, metals, the liquid state and cryogenics. The complete list of papers, together with abstracts and minutes of the Physical Society meeting, are given in the May 15 issue of the *Physical Review* (98, 1144; 1955), where it is also reported that at the business meeting of the Society, the following were elected to hold office for 1955: *President*, R. T. Birge; *Vice-President*, E. P. Wigner; *Secretary*, K. K. Darrow; and *Treasurer*, G. B. Pegram.

The programme of the meeting of the American Association of Physics Teachers (*Amer. J. Phys.*, 23, 306; 1955) consisted of a conference on the role of physics in engineering education; a symposium on visual aids, including an address by Lynn Poole (Johns Hopkins University) on science demonstrations on television; a film session in which two films, one on the properties of liquid helium near the transition point and the other on superconductivity, produced by the United States Bureau of Standards, were shown; a session, consisting of five speakers, devoted to the problem of physics in the secondary school curriculum; a business meeting; and the joint sessions, already mentioned, with the Physical Society. There were nineteen contributed papers. At the business meeting, citations for meritorious service to the Association were voted to W. S. Webb and M. W. Zemansky, and it was reported that a new directory of the Association is to be compiled and distributed this year. The following were elected to hold office for 1955: *President*, R. R. Palmer; *President-elect*, W. C. Michaels; *Treasurer*, F. W. Sears; and *Secretary*, F. Verbrugge.

# COLONIAL TERRITORIES OF THE BRITISH COMMONWEALTH

## REPORT FOR 1954–55

A RECENT Colonial Office report, "The Colonial Territories 1954–55"*, retains its general title of previous years, although, as from October 1, 1954, effect was given to the proposals of the White Paper, "Reorganization of the Colonial Service", and existing unified branches of the Colonial Service became merged in H.M. Oversea Civil Service. During the year, thirty new appointments were made to the Research Branch of the Oversea Civil Service, and thirteen research studentships were awarded to train candidates for research appointments, while two research Fellows are making investigations on behalf of the Colonial territories. The total number of appointments to Colonial territories made through the Colonial Office again decreased, from 1,227 in 1953 to 1,135 in 1954, due to a reduced demand for recruits for some of the smaller branches and special types of appointment. The demand for recruits for administrative appointments was considerably higher. During the year 2,081 men and women employed by Colonial Governments went to the United Kingdom, as against 2,090 in 1953 and 2,013 in 1952, and 673 of them were of Colonial domicile.

The report follows the pattern of previous surveys; it provides an admirable conspectus of political, economic, financial and social developments in the Colonial territories and, apart altogether from the chapter on research and surveys, gives the man of science the essential background against which the achievements recorded in greater detail in another report, "Colonial Research 1954–55", are to be considered. In like manner it provides the essential background for discussion of other particular topics such as the provision of technical assistance to these under-developed areas, the development of higher education, and the recommendations of the East Africa Commission; while its clear presentation, the diary of outstanding events and summary of events and developments in individual territories, with the list of Parliamentary and non-Parliamentary papers of Colonial interest published in 1954–55, go far to make it an indispensable reference work for all interested in Colonial affairs. Indeed, all the essential information seems to be collected here for that popular exposition required to remove the alarming indifference and ignorance among the British people of their Colonial territories upon which Political and Economic Planning commented so strongly in its recent inquiry into Colonial students in Britain.

Nor is matter of scientific interest confined to the chapter on research and surveys. That headed "Constitutional and Administrative" refers to the expansion of the activities of the Falkland Islands Dependencies Survey at bases in the Dependencies in the Antarctic to include *inter alia* geophysical observations at the most southerly base, and for the year 1954–55 a grant of £85,650 was made from United Kingdom funds. The account of economic and financial developments, which reports a more favourable financial year than was expected, as the forecast drop in revenue did not occur, records a rise in expenditure of Colonial Development and Welfare Funds from £14 million in 1953–54 to £15·6 million in 1954–55. Colonial Governments have continued efforts to improve agricultural efficiency by surveys, research, development work, and especially by spreading a knowledge of modern techniques among their peasant farmers. The staffs of Departments of Agriculture are being steadily strengthened, and in territories such as Cyprus, Nigeria, Nyasaland and Zanzibar research work has reached the point where definite recommendations for the use of fertilizers by farms can be made and schemes to encourage their use have been initiated. Much, however, remains to be learned about the best use of fertilizers and of trace elements, and research work continues in all territories. Much attention is also being given to the development of water supplies and of irrigation, where possible. Both in the Gold Coast and in Nigeria the campaign against swollen-shoot disease continued. Staff shortages were no longer a limiting-factor, and good progress was made with cutting-out and with the periodic re-inspection of the affected areas. In Nigeria the sealing-off policy continued to be only partly successful, with new foci of infections being discovered in the disease-free belt around the area of mass infection. It has been decided to inspect all cocoa farms in Western Nigeria once every six months, and the establishment of field overseers has been increased from 143 to 603. Increasing attention is also being paid to the depredations of the capsid bug and of the fungus disease known as black pod, which between them are estimated to destroy up to 20 per cent of the crop each year. In Nigeria, the control of epizootic diseases, such as rinderpest and pleuro-pneumonia, has been most effective, and more than 4·5 million vaccinations were carried out during the year. In the north some 250,000 cattle were treated for trypanosomiasis. Rinderpest control has been a major duty in East Africa, and production of rinderpest vaccines for the East African territories has been transferred to the East African Veterinary Research Organization Laboratories in Kenya. Effective disease-control measures in Uganda gave the main stock-rearing areas an exceptionally productive year in 1954. Interest in fish farming is growing. The preservation of fish is of prime importance in tropical areas. The usual techniques of smoking, drying and salting are practised, and successful pilot experiments in the production of edible fish-meal have been conducted in the Gold Coast and Uganda. Uganda has also been experimenting with killing of 'weed' trees by spraying with hormone preparations instead of the toxic sodium arsenite.

---

* Colonial Office. The Colonial Territories 1954–55. (Cmd. 9489.) Pp. ix+186. (London: H.M.S.O., 1955.) 6s. net.

There was an appreciable increase in the assistance given to Colonial Governments under the Expanded Programme of Technical Assistance: in 1954 the Technical Assistance Board approved projects in fourteen territories providing sixty-four experts and twenty-three fellowships at an estimated cost of 528,000 dollars. Technical assistance from the United States included American specialists giving technical assistance to British Guiana and a programme of grassland and pasture research in West, Central and East Africa. Under the 1953–54 Mutual Security Act, a sterling sum not exceeding the equivalent of five million dollars has been set aside for financing projects for economic development in British territories in Africa. Experts provided by the Food and Agriculture Organization of the United Nations have been working during the year on surveys of the Rufiji Basin in Tanganyika and the Accra Plains in the Gold Coast, while other experts from the Organization are engaged on livestock research in British Guiana and on irrigation problems in Trinidad and Jamaica. Projects initiated or carried forward during the year in co-operation with the regional offices of the World Health Organization include malaria control in Northern Nigeria, North Borneo, Dominica and East Africa, insect control in St. Vincent, yaws control in Jamaica, Grenada, St. Vincent and Fiji, and tuberculosis control in the Somaliland Protectorate.

In December the International Federation of Workers' Educational Associations, in conjunction with Unesco, held a seminar on "Adult Education in a Changing Africa" at the University College of the Gold Coast, while under the Expanded Programme for Technical Assistance Unesco provided the Government of Trinidad with the services of a principal for the San Fernando Technical Institute and the Government of Sierra Leone with an expert on teacher-training. The Commission for Technical Co-operation in Africa South of the Sahara set up a new Inter-African Committee for Social Sciences and convened during August 1954 the second session of the Inter-African Soils Conference at Leopoldville, Belgian Congo. Under the Colombo Plan, thirty-six experts were provided in 1954 and a hundred and seventy traineeships, while requests for forty-eight more experts and seventy-seven more traineeships were under negotiation. Progress in the international co-ordination of the campaign against the desert locust (*Schistocerca gregaria*) in the Arabian peninsula was much slower than expected, and locust swarms produced in Arabia spread to East Africa and reached Nigeria in the west. By the end of 1954 Kenya and Tanganyika were very heavily invaded, the resources of the Desert Locust Control Organization and of the local administration were strained to the utmost, and the further outlook was very grave. The African migratory locust and the red locust continued to be kept under control in their outbreak areas.

Under social services the report records encouraging academic progress in the four Colonial university colleges, the opening of new library accommodation at the Royal University of Malta and an increase in university students from 3,639 to 4,010. Contracts were signed for the erection of most of the major buildings of the Nigerian College of Arts, Science and Technology at its headquarters at Zaria, while the third branch was being built at Enugu in the Eastern Region. Good progress was also made towards the completion in Nairobi of the new buildings of the Royal Technical College of East Africa. In Malaya a six-year programme of controlled expansion of education is expected to bring expenditure to £16,800,000 by 1960, when there will be more than a million children in all types of school; and a second training college for Malayan teachers in the United Kingdom was being established at Brinsford Lodge in Staffordshire. The most spectacular event of the year in education was the provision of primary education for all who desire it in Western Nigeria, and some four hundred thousand children were registered; a large number of secondary schools was also opened in January. In the Gold Coast the emphasis of expansion is now on secondary rather than on primary education, while large-scale educational development in Uganda included the expansion of technical education as well as of primary and secondary schools. Educational exchanges under the Fulbright Act included two lecturers, six research scholars and one graduate student from the United

States to institutions in Colonial territories, while five awards to teachers from the United States working at schools in the Colonial territories were renewed.

Generally, there is evidence of growing mastery in the Colonies over preventable diseases and of increased public understanding of their causes and the logical basis of measures taken against them; but the freedom from major epidemics was marred by outbreaks of acute anterior poliomyelitis in Jamaica and Trinidad, both of which have also had to combat typhoid in endemic form. Abnormal social conditions caused by overcrowding increased the incidence of communicable disease in Hong Kong, and falling infantile mortality and general death-rate, together with a high birth-rate, make it difficult to provide a medical service in Singapore adequate for the needs of a rapidly increasing population. Famine conditions were again present in the Mayoni, Dodoma and Mpapwa districts of Tanganyika, an invasion of the army worm destroying crops which had survived the drought. A striking feature of the year was the extent to which large-scale operations of the health departments was assisted and promoted by the World Health Organization and the United Nations Children's Fund, the scientific backing, financial support and material aid of which permitted many schemes to be carried out that would have been beyond the unaided resources of the territories. Malaria has ceased to be a public health problem in Cyprus and Mauritius, and for the first time the total number of deaths from malaria in the Federation of Malaya fell below a thousand, attributable to the protection in rural areas alone of more than half a million persons by house spraying. The death-rate from malaria in Trinidad is also steadily falling, but the hyperendemic areas of tropical Africa still constitute a great challenge. Research and experiment have continued extensively, and in western Sokoto in Northern Nigeria control is being attempted in an area of six hundred square miles containing a population of 124,000, with a controlled residual spraying technique which has already been used in eighty thousand huts and houses. Recruitment of nursing sisters from the United Kingdom and Commonwealth countries remained difficult; but many more Colonial student nurses are now in training in hospitals in the United Kingdom, and the training of nurses in the Colonial territories is developing rapidly.

The chapter on research and surveys deals with work and investigations which are covered more fully in "Colonial Research 1954–55", and it is unnecessary here to refer to more than a few outstanding features of the year. It is expected that some £8 million will be available for expenditure on research during the period 1955–60; but there is still a shortage of scientific staff both in the United Kingdom and in the Colonial territories, and a very definite improvement in recruitment will be needed if the new annual ceiling of expenditure is to be approached. During the year fifty-two research schemes, estimated to cost £533,548, were approved, and increased assistance to Colonial research projects was also given by extending the arrangements for visits overseas by specialists from the United Kingdom and by strengthening the pools of entomologists, plant pathologists and soil surveyors whose members are available for short-term assignments. The East African Agriculture and Forestry Organization is well established, and its investigations into maize rust-resistance promise early control of this disease. The work is closely linked with that of the Maize Rust Research Unit in West Africa. The second of a series of Anglo-French Research Conferences was held at Bambey, Senegal, to discuss work on groundnuts and millets. The research team of the Joint Fisheries Research Organization for Northern Rhodesia and Nyasaland continued the survey of Lake Nyasa from the Nkata Bay base and has revealed remarkable formations on the lake floor. A site in Malacca was selected for the Fish Culture Research and Training Institute, and it is hoped that the building will be complete by the end of 1956. In the Federation of Malaya intensive investigations into filariasis were in progress in the State of Pahang, and heavy doses of dieldrin were effective for six months against the *mansonia* species of mosquitoes, the main vectors in this region. Notable progress was made by the Regional Virus Laboratory, Trinidad, in the study of the viruses of the East Caribbean region. The Central Trypanosomiasis Laboratory at Sukulu, Uganda, was completed and partly occupied, and at Mariakani in Kenya cattle exposed to attack from tsetse but treated with injections of 'Antrycide' pro-salt every two months for more than two years acquired and maintained resistance to strains of *T. congolense*. The review includes some strong criticism of the attempts at the United Nations General Assembly to discredit the work of the Trusteeship Council and castigate the administering authorities, and its clear factual statements amply indicate the unrealistic nature of such attempts.

# ROYAL GREENWICH OBSERVATORY

## ANNUAL REPORT FOR 1954–55

THE annual report of the Astronomer Royal for the period May 1, 1954–March 31, 1955*, deals with the Royal Greenwich Observatory under the headings of Greenwich, Abinger, Herstmonceux and Hartland.

The main mirror of the Yapp 36-in. reflector was removed during the winter and sent to Messrs. Cox, Hargreaves and Thomson for a test of its figure, but none of the suspected 'patchy errors of figure' or astigmatism was found. If, however, colour-temperature work is resumed, re-figuring would be an advantage.

The instruments and equipment of the Physics and Optics Laboratory at Abinger are in course of transfer to Herstmonceux. The Admiralty Civilian Hospital at Feldemore, Holmbury St. Mary, which provided accommodation during the past nine years for many of the Abinger staff, was closed on February 13. It is intended to use some of the rooms for stores and other official purposes.

At Herstmonceux, repairs to the west tower of the south gateway are nearing completion, and portions of the stonework which had been badly weathered have been rebuilt. The unsafe upper portion of the tower was dismantled and has been rebuilt. In the Meridian Group of buildings, the painting of the Cooke reversible transit circle building is completed and entrance steps have been provided. The small pavilion to house the Bamberg small transit and the pavilion for the photographic zenith tube have been erected. A new pavilion for the Melbourne reversible transit circle is to be erected, and will be generally similar in design and dimensions to the Cooke building. In the construction of the equatorial group, the steel frameworks of the domes of the 30-in. reflector, the Schmidt reflector and the 26-in. refractor have been erected, and, as soon as the domes have been completed, it is planned to commence the erection of the telescopes.

---

* Report of the Astronomer Royal to the Board of Visitors of the Royal Greenwich Observatory. Pp. 33. (Herstmonceux: Royal Greenwich Observatory, 1955.)

The ground at Hartland, North Devon, the future site of the Magnetic Observatory, has been purchased, and the civil engineer-in-chief has prepared detailed drawings of the buildings which, it is expected, will be completed in time for observations to be commenced before the beginning of the International Geophysical Year (July 1957–December 1958). One of the buildings to be used for testing magnetic instruments will contain a system of large coils designed to provide artificial horizontal and vertical fields, comparable with those at any point upon the surface of the earth.

Cosmic-ray recording with the Clintel apparatus was continued until February 9, 1955, when one-half of the sensitive area was modified. This was done in accordance with the recommendations of the Cosmic Ray Commission of the International Union of Pure and Applied Physics, with the object of detecting only the flux of mesons capable of penetrating 10 cm. of lead, and entering from a smaller solid angle around the zenith than the previous arrangement would accept. The other half will soon be similarly modified. These modifications are required to make the data comparable with those obtained by many other stations, thereby facilitating the study of world-wide distribution and changes of this flux.

Full-scale meteorological observations have been maintained on a routine basis, and monthly reports have been submitted to the Meteorological Office. Those who remember the conditions last summer will not be surprised to learn that, during the four months May–August 1954, there was a deficiency of sunshine of about two hundred hours as compared with the mean of the preceding four years. The total amount of clear sky at night during the same period was also well below the totals for the preceding years, but the cloudiness was less marked at night than during the day-time. Unbroken trails of δ Ursae Minoris were recorded on twenty nights, while no records were shown on seventy-nine nights.

It was mentioned in the report for 1953–54 and is again referred to in the present report, that the first part of the "Nautical Almanac" for 1960 has been re-designed to meet the recommendations of the International Astronomical Union. Beginning with the 1960 editions, "the American Ephemeris and the Nautical Almanac shall be, apart from a few introductory pages, identical publications". H.M. Nautical Almanac Office will be responsible for the first part of the "Almanac", and the U.S. Nautical Almanac Office for the second part. While no substantial change of content or arrangement will be involved, there will not only be a considerable reduction in price, but the scheme should also lead to wider international co-operation in the field of astronomical ephemerides.

Further tests of the figure of the 98-in. disk of the Isaac Newton telescope were made by Prof. R. O. Redman at the works of Sir Howard Grubb, Parsons and Co. during the works holiday period in August. While the figure was found to be appreciably free from astigmatism, the tests showed some differences from those previously made, and the mirror has been put aside for further tests, for which there is ample time as the telescope will not be constructed for some years.

At the end of the report reference is made to the participation of the Observatory in the general programme of work to be undertaken during the International Geophysical Year, which will require additional staff at the Observatory. The removal from Greenwich to Herstmonceux has reached a stage at which full observing programmes can shortly be commenced, and for these the present staff of the Observatory is seriously inadequate. In a separate memorandum proposals for the adequate staffing of the Observatory will be submitted to the Board of Visitors. If the Board of Admiralty approves, the additional staff required for the special programmes during the International Geophysical Year can be provided for this increase and afterwards absorbed into other observational programmes.

---

# WORK STUDY AND SOME RESULTS

Work study methods are quite common in American industry and have proved their efficacy. In Britain, industrial organizations have been slow in introducing these techniques, and this is one of the reasons why productivity lags so much behind that of the United States. Were it not for chemical manufacturers in Britain, the rate of introducing work study would have been even slower than it has been. Once more they have placed the whole of British industry in their debt by producing two most practical booklets (Association of British Chemical Manufacturers. 2*s*. 6*d*. each). The first describes effective ways of introducing work study into individual firms, and the second gives an account of some of the results which have been achieved.

The first booklet describes the nature of work and the benefits accruing from it; the kind of man who should be appointed as work study officer and the way in which he should be trained; the organization and content of work study appreciation courses for senior, middle and junior management; the means of obtaining co-operation with the trade unions; the kind of jobs which should first be investigated; and the employment of consultants.

The results obtained by using work study methods in fourteen chemical firms differing in size, complexity and the goods they produce are described in the second booklet and form a valuable series of case histories which should encourage the lagging and give succour to the faint-hearted. In the case of Hardman and Holden, Ltd., for example, the labour cost of one product was reduced by 50 per cent; output in one plant increased by 40 per cent by a change in procedure, with an increase in labour force of 12 per cent over the original. In one process there were seventeen handling operations in the finishing stage of the product. These have now been reduced to one—with a resultant saving of 30 per cent in man-power and the elimination of the use of two machines. Because of the building up of intermediate stocks between two processing operations it was originally thought it would be necessary to increase the capacity of the second plant; work study demonstrated that by a change in operation the second unit could deal with the whole of the output of the first unit—and this has been effected.

In Imperial Chemical Industries, Ltd., four examples testify to the improvements which have been made by the introduction of work study. Thus, a drum washing plant team was reduced from five to three men and the total output increased by 50 per cent, representing a saving of £1,200 a year.

A procedure for bagging powder had been operated for several years, during which time there had been minor changes in the requirements of sieving and blending, and the material of the bags had changed. No obvious improvement of the long-established method appeared possible, but careful study of method indicated the possibility for a better flow of materials. As a result, the distance the powder was moved was reduced by almost 60 per cent and the distance the operator moved for each bag of powder was reduced by nearly 50 per cent. With no change in the level of production, it was possible to reduce from two operators to one. In the third example, cast-iron cooling-water pipes have to be tested under pressure and checked for straightness. By the original method used, two men could test 180 pipes in a day. Method study showed various possible improvements, and the one selected involved changes in equipment which cost only £25. One man can now test two hundred pipes in a day, and no incentives are involved in this case.

In another works, the inspection and servicing of cars and lorries was changed to a carefully worked out basis of incentive. As a result, the four shift operatives increased their output by 48 per cent and earned 26 per cent more, with a reduction in labour cost per unit of output of more than 15 per cent.

---

# IMMUNOLOGICAL DISCRIMINATION BETWEEN THE BLOOD OF NORMAL AND OF TUMOUR-BEARING RATS

By Dr. D. A. DARCY

Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), London, S.W.3

USING the gel diffusion technique of Ouchterlony[1], it has been found possible to distinguish the blood plasma (or serum) of rats bearing transplanted or induced tumours from the plasma of normal rats or rats bearing homografts of normal tissues.

The method was, first, to prepare antisera of high precipitin titre in rabbits by injecting them with the plasma or serum of (*a*) normal rats or (*b*) rats bearing the transplanted Walker tumour. Other rabbits were inoculated with the cells of the Walker tumour; but the antisera so obtained had only very weak discriminatory power, no more than would be expected from the incidental contamination of the inoculated cells with plasma. When antisera of satisfactory strength had been obtained, they were allowed to diffuse through an agar gel to meet and react with the antigens (rat plasma) diffusing in the opposite direction. In this way a series of bands or lines of precipitate was formed in the gel giving a 'spectrum' characteristic of the antigenic structure of the plasma in question, the antigen structure being determined by the proteins, and possibly other soluble substances. It was found that the precipitin spectrum of the cancer plasma differed from the normal in a characteristic way.

A variety of transplantable rat tumours was employed, namely, the Walker tumour, the Yoshida sarcoma, the *R*48 sarcoma, the *GD*-1 tumour, the August tumour and a sarcoma induced by means of xanthine. The induced tumours were a series of sarcomas of various sizes arising at the site of implanted pellets of benzpyrene, and one hepatoma induced by feeding butter yellow. The rats used throughout both for controls and for tumour-bearing were from a colony of non-inbred white rats originally derived from the Wistar strain, the only exceptions being that the August tumour and the Yoshida tumour were grown in the August and *BD*-1 strains, respectively. The control plasmas came from rats which were either untreated or which bore homografts of normal tissue (liver and skin) at various stages of evolution.

Agar diffusion plates were prepared with three wells as shown in Figs. 1 and 2. The bottom well was charged with antiserum and the left and right wells with cancer and normal plasma, respectively. The lines of precipitate are composed of the various antigenic components in combination with their corresponding antibodies. When a line on one side fuses with one on the other side to form an arc, the antigenic components in question are identical[1]. When an arc is displaced to one side, this indicates a lower concentration of the antigen on that side. When a line crosses to the opposite side without fusing or without deviating, the substance in question is either absent or in negligibly low concentration on that side.

The antiserum prepared against normal rat plasma (A.N.P.) was used in a large number of plate tests to compare the different cancer plasmas with the plasmas of the normal or grafted controls. Both pooled and single control plasmas were tested. It was found that the cancer plasmas differed from the controls in having a group of rather faint lines (labelled *K* in Fig. 1) advancing towards the antiserum in front of the strong line which is the leading line (*A*, Fig. 1) of the normal spectrum. The *K* group was composed of two lines at first, but later others which may be 'immunological artifacts'[2] appeared among them. The *K* lines were shown most strongly by the blood of animals bearing advanced tumours; but the antigens were clearly demonstrable in the blood as early as six days after implantation of the Walker tumour. The lines appeared to fuse with an unidentified group in the normal spectrum; the simple interpretation of them would be that they represent substances which are in higher concentration in the cancer blood than in the normal. However, it was found that a similar group of *K* lines could be produced by autolysed whole normal rat blood, and occasionally by normal rat plasma that had been stored for a very long time. It is suggested, therefore, that the *K* lines may represent partially broken-down substances (probably protein) which can diffuse faster than the parent substances

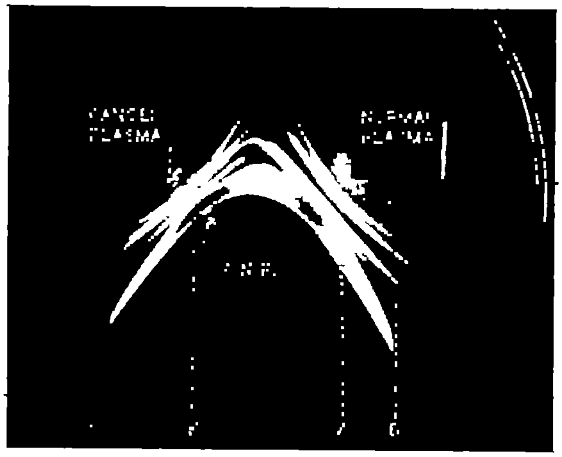

Fig. 1. A plate after nine days diffusion at room temperature. The cancer plasma comes from a rat bearing a 13-day old Walker tumour. The normal plasma was a pooled mixture from untreated controls. Both plasmas were diluted one part in ten with citrated saline. The antiserum (A.N.P.) had been prepared against normal rat plasma

while retaining their original antigenicity. Atypical single *K* lines were also occasionally found in the plasmas of control rats described as 'bandaged and fed' (see below). A second difference observed was that the line *A* was actually farther from the antibody well in the cancer plasma than in the normal, indicating a lower concentration of the antigen in question in the cancer blood. Certain other antigens in the cancer plasma appeared to be in lower concentration, often to a striking degree (for example, line *B*, Fig. 1) than in the normal. The reverse was also found, namely, an antigen or antigens in the cancer spectrum much stronger than in the control.

When the antiserum employed in the gel plates was that prepared against the plasma of animals bearing the Walker tumour, a more striking distinction was obtained. In addition to a *K* group and a weaker *A* antigen, the cancer plasmas now showed a line which was absent entirely from the pooled normal plasma (Fig. 2). If the antiserum was then absorbed to exhaustion with normal plasma, it still reacted with the cancer plasma either in the 'ring' test in glass tubes, or in the gel plates to give a band of precipitate. The blood plasmas of all animals bearing well-established tumours, including most six-day old Walker tumours, were found to give strongly positive ring tests with the absorbed antiserum, whereas the great majority of controls were negative. Blood plasmas of other species (man, mouse, hamster) bearing induced or spontaneous tumours were also negative.

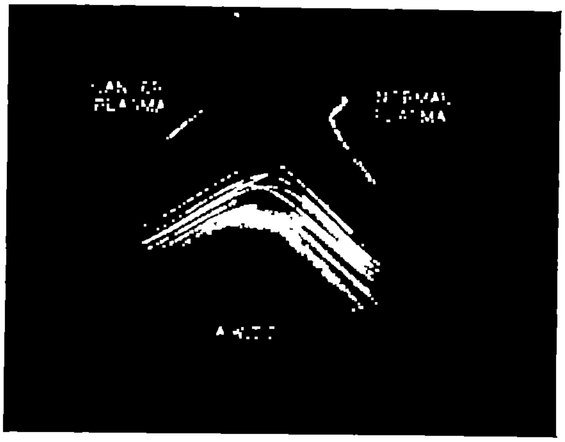

Fig. 2. A plate after ten days at room temperature. The cancer plasma was from a rat bearing a 12-day old Walker tumour. The normal plasma was a pooled mixture from untreated controls. Both plasmas were diluted one part in fifteen with citrated saline. The antiserum (A.W.T.P.) had been prepared against the plasma of animals bearing Walker tumours

A small percentage of control plasmas, all coming from a group of rats which had received skin homografts, however, was positive. Further investigation of this point showed that the skin grafting itself was not responsible, but that the effect was caused by the tight plaster bandage on chest and upper abdomen (such as is commonly used for skin grafting in rats and mice[3]) acting in conjunction with insufficient fasting of the rats before bleeding. The bandage alone had no effect, and complete lack of fasting produced, at best, faint or doubtful positives. The two acting together produced strong positives. This antigen, therefore, cannot be regarded as cancer-specific; but it is interesting that it should be absent from blood of normal fasting rats. It was present in the blood of tumour-bearing animals even when they were starved for a day before bleeding, and even when the tumour was inoculated in the hind leg so as to avoid any possible 'corset' effect such as might occur when the tumour was grown in the usual way in the animal's side.

From this evidence it seems likely that the antigen in question is a lipid or lipoprotein. Lipids are found in relatively high concentration in the blood of tumour-bearing rats[4]. It was an easy matter to distinguish the plasma of the rats which had been bandaged and fed before bleeding from true cancer plasmas by means of the characteristic *K* antigens and the weaker *A* antigen of the latter.

None of the above antigen-lines has been identified chemically. However, special methods are becoming available for this purpose[5], so that a complete characterization of the precipitin spectrum should eventually be possible. It may be speculated, for example, that the line labelled *A* in the spectrum represents serum albumin; this protein has a smaller molecule than the globulins and would be expected to diffuse ahead of them; it is, furthermore, reported to occur in lower concentration in cancer blood than in normal[6].

In conclusion, it may be said that while the present results represent only a preliminary survey, the determination of the precipitin 'spectrum' of blood and other body fluids offers interesting possibilities clinically for diagnostic and other purposes, and experimentally in a wide variety of fields.

This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

## Ferroverdin, a Green Pigment containing Iron produced by a Streptomycete

DURING a search for antifungal antibiotics, a streptomycete was isolated from a sample of soil from Leopoldsville (Belgian Congo) which produced an intense green non-diffusible pigment on yeast agar. The streptomycete producing this pigment is not identical with any of the following species stated to produce green pigments: *S. verne*, *S. viridans*, *S. virgatus*, *S. flavovirens*, *S. viridis*, *S. viridochromogenes*. Its morphological and cultural characteristics indicate that it may be a new species.

The green pigment can be produced in submerged culture in shake flasks and in stirred fermenters on a medium containing 0·5 per cent yeast autolysate and 1 per cent glucose, *p*H 7; good aeration is essential for its production.

The pigment is extracted into ethanol from the wet mycelium, transferred into butyl acetate and the butyl acetate solution percolated through a column of alumina (Merck). The column, which retains the pigment adsorbed at the top, is developed with 95 per cent ethanol followed by absolute ethanol.

Three green bands separate, one remaining immobile at the top, one moving quickly down the column and one, representing the main fraction, following the fast-moving band. The pigment from the main fraction has been obtained in the crystalline state after repeating the chromatographic procedure and concentrating the final ethanolic solution. The yield of the crude crystalline product is about 100–200 mgm. per kgm. (wet weight) of mycelium. After recrystallization from methanol, elementary analysis showed a composition in good agreement with the formula $C_{30}H_{24}O_8N_2Fe$ (found: C, 60·0; H, 4·1; N, 4·7; Fe, 9·3 per cent; calculated: C, 59·8; H, 4·05; N, 4·73; Fe, 9·3 per cent). In view of its colour and its iron content, the pigment has been named 'ferroverdin'.

Ferroverdin is insoluble in water, benzene, petroleum ether, chloroform and carbon tetrachloride, but is soluble in methanol (about 5 mgm./ml.), ethanol (about 2 mgm./ml.), acetone (about 15 mgm./ml.) and glacial acetic acid (about 15 mgm./ml.). It is readily reduced by hydrogen gas, in the presence of a palladium – barium sulphate catalyst, absorbing 6 mol. of hydrogen. The reduced solution is colourless and does not develop colour on shaking with air.

In the visible spectrum ferroverdin absorbs at 4300 and 6700 A. ($\varepsilon_{4300} = 1·10 \times 10^4$, $\varepsilon_{6700} = 1·10 \times 10^4$; it also absorbs strongly in the ultra-violet region with peaks at 2765 and 3000 A. ($\varepsilon_{2765} = 6·18 \times 10^4$; $\varepsilon_{3000} = 5·12 \times 10^4$. After reduction it shows peaks at 2340, 2710 and 3125 A. ($\varepsilon_{2340} = 3·33 \times 10^4$, $\varepsilon_{2710} = 1·37 \times 10^4$, $\varepsilon_{3125} = 7·2 \times 10^3$ (solvent methanol).

The iron is firmly bound in ferroverdin, but appears in ionic form after catalytic reduction. It is gradually released by hydrolysis at 100° C. in 2 *N* hydrochloric acid and in 2 *N* sulphuric acid. Investigations of its chemical structure are in progress.

We thank Dr. G. Gualandi and G. Serlupi for the spectrophotometric measurements and acknowledge with thanks the collaboration of Dr. A. Ballio in the initial stages of this work. We also thank Mr. F. Zanchi and the staff of the fermentation pilot plant of this Institute for their co-operation in the production of ferroverdin, and Mr. J. Daymond for technical assistance.

## A Brain Factor influencing the Viability of Neurotropic Rift Valley Fever

DURING experiments on the viability of Rift Valley fever it was noticed that crude extracts of virus-infected brain tissue in 10 per cent rabbit, sheep or human serum were less stable than the virus partially purified by differential ultra-centrifugation and suspended in the same diluents. In Fig. 1 this difference in viabilities is shown. Curve (*a*) shows the survival at 37° C. of virus in a crude or unpurified suspension of four virus-infected adult mouse brains in 40 ml. of 10 per cent rabbit serum saline. Curve (*b*) shows the survival of partially purified virus stored under the same conditions. It will be noticed that the disappearance of the virus in the partially purified material followed the exponential law, whereas the unpurified material showed an increasing rate of inactivation with time.

The factor responsible for the rapid inactivation of the virus is present not only in emulsions of virus-infected tissues but also in 10 per cent serum saline extracts of uninfected or normal mouse brain. In Fig. 2, viability curves are shown of purified virus suspended in normal brain extracts (4 brains in 40 c.c. rabbit serum saline) in two separate experiments (*a*), and that of purified virus in 10 per cent rabbit serum saline (*b*).

The factor is probably not a protein as no fraction capable of inactivating the virus was precipitable from brain emulsions by ammonium sulphate between 0 and 100 per cent saturation.

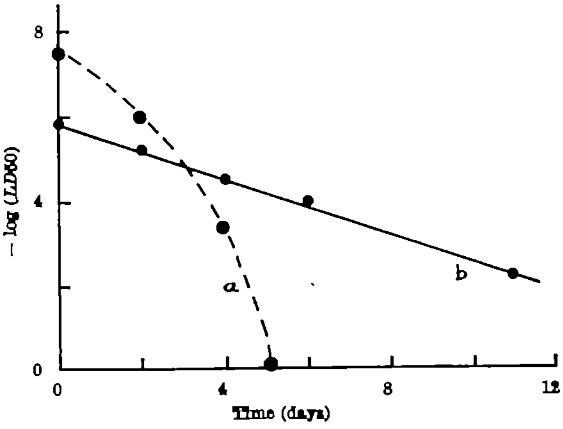

Fig. 1. Survival or viability curves of neurotropic Rift Valley fever at 37° C. (*a*) Crude infected brain suspension in 10 per cent serum saline; (*b*) partially purified virus in 10 per cent serum saline

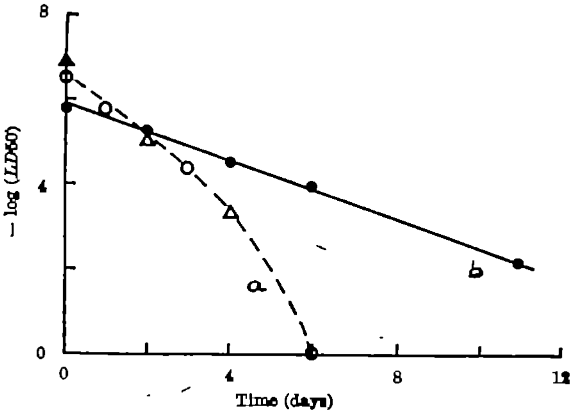

Fig. 2. Survival or viability curves of neurotropic Rift Valley fever at 37° C. (*a*) Partially purified virus in normal brain extracts in 10 per cent serum saline; (*b*) partially purified virus in 10 per cent serum saline

The virus-inactivating factor could be separated from brain emulsions by dialysis through 'Cellophane' membranes. In a typical experiment thirty-two normal brains were emulsified in 32 ml. 10 per cent rabbit serum saline and dialysed for six days at 37° C. against 32 ml. 10 per cent rabbit serum saline in the presence of penicillin and streptomycin. At the end of this period both the contents of the 'Cellophane' bag as well as the dialysate were free of aerobic and anaerobic bacteria. Virus purified by differential centrifugation was mixed with the dialysate, and the period of survival at 37° C. determined. Purified virus in 10 per cent rabbit serum saline stored in the same incubator served as control. The results are recorded in Fig. 3; ($a_1$) and ($a_2$) are the viability curves for the virus in brain dialysate in two experiments, and (*b*) that for the purified virus in serum saline. The rapid inactivation of the virus suspended in the dialysate indicated that the factor responsible is of low molecular weight and dialysable.

Because of the non-linear relationship between the titres expressed as negative log $LD_{50}$ and time of incubation in the cases where the inactivation factor is present, it would appear that either this factor was produced during autolyses of the brain tissue, or it was a substance that becomes more toxic for Rift Valley fever on storage at 37° C.

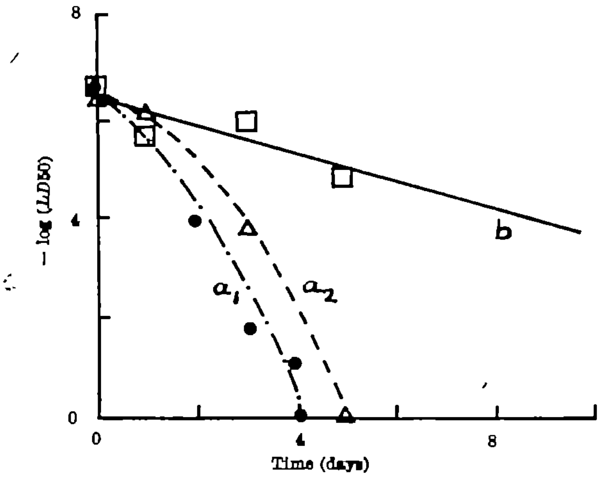

Fig. 3. Survival or viability curves of neurotropic Rift Valley fever at 37° C. ($a_1$) and ($a_2$) Partially purified virus in dialysate from normal brain emulsion in 10 per cent serum saline; (*b*) partially purified virus in 10 per cent serum saline

This factor might also play a part in determining the viability of such unstable neurotropic viruses as rabies and yellow fever. It is probably different from the antiviral substance or substances extracted with organic solvents by Casals and Olitsky[1] from normal mouse and sheep brains, as tests have shown that it is insoluble in chloroform.

We would like to thank Prof. M. van den Ende for his interest in this work and Dr. R. A. Alexander for generous supply of virus.

## Ramnacin: a New Antibiotic from a *Streptomyces* sp.

In the course of an investigation on antibiotics from micro-organisms of East Pakistan soils, a *Streptomyces* sp. producing a new antibiotic was isolated. The cultural and other characteristics of the organism are being described elsewhere[1]. The organism was surface-cultured on the medium shown in Table 1; 500-ml. quantities of the medium were used in 1,000-ml. fermentation flasks and sterilized at 15 lb./sq. in. steam pressure for 20 min.

Table 1

| | | | |
|---|---|---|---|
| Glycerine | 30 00 gm. | KCl | 0 50 gm. |
| Gram extract (chick pea) | 2·50 ,, | $CaCl_2$ (anhydrous) | 0 30 ,, |
| $MgSO_4.7H_2O$ | 0·50 ,, | $FeSO_4.7H_2O$ | Trace |
| $K_2HPO_4$ | 1·00 ,, | Agar | 1·50 gm. |

The above was dissolved in tap water and the calculated amounts of KI, $MnSO_4$, $ZnSO_4.7H_2O$ were added to supply 2 p.p.m. of iodide, manganese and zinc in the medium, which was made up to 1,000 ml. The *p*H was adjusted to 7·4.

The medium was then inoculated with spores from test-tube slants (Czapek–Dox medium, *p*H 7) and incubated at room temperature, 21–25° C. The maximum antibiotic activity was found after 30 days incubation. The activity was measured in terms of inhibition zones in the usual cup plate assay[2] with *Bacillus subtilis* N.C.I.B. 3610 as the test organism.

When the maximum activity had been obtained, the culture fluid was filtered through a wire net (as used in filtering tea). The *p*H of the filtrate was adjusted to *p*H 8 and then it was extracted with an equal volume of ether. The mycelia, which held most of the antibiotic, were crushed with mortar and pestle under sand and extracted several times with ethanol. The latter was removed *in vacuo* and the residue suspended in water adjusted to *p*H 8 and extracted with ether with a little alcohol to break down an emulsion that formed occasionally. There was little antibiotic left in the aqueous suspension after extraction with ether. The ether extract was then added to that already obtained from the culture filtrate. The combined ether extract was evaporated to dryness on a water-bath and the residue chromatographed in chloroform on activated alumina (B.D.H.). The active material moved almost with the solvent front, accompanied by a small amount of colouring matter which was, however, easily eliminated during crystallization of the antibiotic from petroleum ether–alcohol mixture. It melted at 235° C. (Kofler hot stage) and contained only carbon, hydrogen and oxygen (analysis[3]: C, 64·51; H, 8·97 per cent; molecular weight, 499 (Rast, camphor)). The molecular formula as calculated on this basis is $C_{26}H_{44}O_{8}$.

The crystalline material is sparingly soluble in water. It is highly soluble in alcohol, acetic acid, ethyl acetate, chloroform, ether and to a lesser extent in benzene and petroleum ether (80–100° C.). It does not decolorize bromine in carbon tetrachloride, and gives a positive test for benzenoid structure[4]. Paper chromatography of the combined extract of culture filtrate and mycelia with *n*-butyl alcohol/acetic acid/water (4 : 1 : 5) revealed only one active substance with an $R_F$ value of 0·92. The position of the active material in the paper was determined by plating on a nutrient agar medium seeded with the test organism and developed after overnight refrigeration. Counter-current distribution analysis with an improvized apparatus made of twenty separating funnels using petroleum ether (b.p. 80°–90° C.), 95 per cent alcohol and water (4 : 3 : 1) gave only one peak of activity.

The antibiotic is highly stable. Autoclaving at 15 lb./sq. in. steam pressure for 20 min. at *p*H 2–10 left all activity practically unimpaired. The melted substance (m.p. 235° C.) also retained its activity. It is, however, destroyed, presumably by contaminant micro-organisms, if the culture broth is left exposed.

The antibiotic was tested for activity against a number of micro-organisms, with the results shown in Table 2.

Table 2. ANTIMICROBIAL SPECTRUM OF 'RAMNACIN'

| Organism | Activity |
|---|---|
| Bacteriae: | |

## Tetrazolium Salts as Viability Indicators: Radiation-catalysed Reactions

TETRAZOLIUM salts have found various uses in both plant and animal tissues, and in the past six years more than seventy papers as well as several reviews[1] have appeared. But one of the most commonly used of these salts, 2,3,5-triphenyl tetrazolium chloride, can be reduced in various ways, as, for example, by certain naturally occurring compounds carrying —SH groups, if the *p*H[2] is greater than 9, by glucose[3] at temperatures exceeding 40° C. and by water[4] if exposed to strong radiant energy of wavelengths shorter than 450 mμ, especially at high *p*H[5]. Also extracted dehydrogenases and oxidases have caused reduction of triphenyl tetrazolium chloride *in vitro* (see, for example, ref. 6), and reducing agents like sodium hydrosulphite reduce it readily. Radiation can also cause some other curious effects, which I wish to report briefly.

I have verified the findings of Brown[7], namely, that suspensions of various oils could catalyse the light-induced reduction of triphenyl tetrazolium chloride, some oils being more active than others. Linseed oil and cedar wood oil, for example, were more effective than mineral oil (paraffin oil). A 750-watt mercury-vapour lamp was used and the suspensions, buffered to *p*H 7, were kept 1 ft. away in glass vials immersed in a 'Lucite'-walled water-bath maintained at 16° C. However, these reductions did not occur in the dark, and this is of considerable importance to seed testing and cytological work, a point to which Brown does not refer.

Brown also inferred that the results of Dyar[8] with blue tetrazolium (a ditetrazolium salt with 2-methoxy groups) were at fault in view of Brown's results with triphenyltetrazolium chloride. But I found blue tetrazolium was not affected by radiant energy including ultra-violet radiation, whether in aqueous solutions or in the presence of oil suspensions, even at *p*H up to 9. This seems to strengthen Dyar's conclusion that blue tetrazolium may be taking part in the Hill reaction in the presence of illuminated chloroplasts.

I also found that yeast (*Saccharomyces cerevisiae*) could further catalyse radiation-catalysed reduction of triphenyl tetrazolium chloride, so that this radiation-induced reaction was more rapid than with yeast in the dark or radiated aqueous solutions of the salt. In fact, even weak light from the window accomplished this acceleration of reduction in yeast–water suspensions to which equal amounts of 0·5 per cent triphenyl tetrazolium chloride buffered to *p*H 7 and 3 per cent glucose had been added. This proved to be a property of the cells themselves and not the substrate. However, dead cells (boiled), which would not reduce triphenyl tetrazolium chloride in the dark, did further catalyse the radiation-catalysed reduction of that salt, although not to such an extent as living yeast cells. It was also found that ground-up cells from which an extract was obtained by filtering through a bacterial filter could also further catalyse this radiation-catalysed reduction of triphenyl tetrazolium chloride. This reaction was largely inhibited by monoiodoacetate or sodium fluoride at $1 \times 10^{-3}$ *M*.

Perhaps this helps to explain the rapid reduction noted by Gunz[9] in yeast with triphenyl tetrazolium chloride, since he did not mention light. Gunz states that yeast was not inactivated [would still reduce the salt] by suspension in acetone or absolute alcohol for two periods of half an hour and subsequent drying, or air drying. Also, according to his table, air-dried yeast did not cause fermentation but did reduce triphenyl tetrazolium chloride. These results are rather puzzling. Drying yeast in the air and then re-suspending it in water with substrate may result in no fermentation at first, but there is nothing to prevent the yeast from growing from a spore stage and eventually causing fermentation. Also I found that soaking yeast in either acetone or ethyl alcohol solutions of more than 50 per cent concentration for 1 hr. with subsequent drying and re-suspension in water resulted in complete inactivation of the reduction of triphenyl tetrazolium chloride, while soaking the cells in 16 per cent acetone or alcohol for 24 hr., followed by drying and re-suspension, did not inactivate them. Cells of onions soaked in concentrated acetone for 1 hr. with subsequent washing and immersion in 0·5 per cent triphenyl tetrazolium chloride did not show the reduction reaction in the dark.

It appears, therefore, that although reduction of triphenyl tetrazolium chloride may not always be a good indication of viability in the sense that the entire respiratory mechanism is still functional, the lack of reduction in cells normally reducing it is a fairly certain sign that death has occurred. Avoidance of light is especially important in the case of triphenyl tetrazolium chloride, but not in that of blue tetrazolium. Oxygen tension must not be excessive.

## Maximum Likelihood Calculation of *Rh* Gene Frequencies in Pacific Populations

In general, the calculation of maximum likelihood[1,2] estimates of gene frequencies requires the preliminary calculation of trial values, followed by the computation of corrections to the trial values, by a method which is essentially Newton's method of successive approximations for getting a root of an equation. In many Pacific populations (Gilbertese, Fijians, etc.), only four or five *Rh* types $CDe/C$ ($R_1R_1$), $CDe/c$ ($R_1r$), $CDE/c$ ($R_1R_2$), $cDE$ ($R_2$), and occasionally a little $cDe$ ($R_0$) are present[3], and the composition of the population can be explained by assuming that only three genes, $R_1$, $R_2$, and $R_0$, are present. For such cases the maximum likelihood equations can be solved explicitly, and the best estimates of the gene frequencies obtained without any process of successive approximations. If we designate the frequencies of the five phenotypes, in the order just mentioned, as $\overline{H}$, $\overline{K}$, $\overline{P}$, $\overline{T}$ and $\overline{Q}$, the solution of the maximum likelihood equations gives the following formulæ:

$$R_1 = \overline{H} + \overline{K}/2 + \overline{P}/2$$

$$R_2 = \frac{4(1-R_1) + \overline{P} - \sqrt{[4(1-R_1)+\overline{P}]^2 - 16(\overline{P}+\overline{T})(1-R_1)}}{4}$$

$$R_0 = 1 - R_1 - R_2$$

If desired, standard errors can be calculated in the usual way.

The derivation of these formulæ, and illustrative calculations, will be published elsewhere.

If the gene $R_z$ is present, as in Indonesians[4], an additional phenotype, $CDE/C$ ($R_1R_z$), whose frequency we may designate as $\overline{J}$, is present, and the above formulæ will not work. Williams[5] has published a modification of Fisher's method of free parameters which is applicable to such data. The same results can be obtained a good deal more simply by using the formulæ published[6] for dealing with the *MNS* system, to which this particular *Rh* system is exactly similar. It is only necessary to make use of the following equivalences:

| Short symbol | Phenotype | Equivalent *MNS* phenotype |
|---|---|---|
| *H* | *CDe/C* | *M* |
| *J* | *CDE/C* | *MS* |
| *K* | *CDe/c* | *MN* |
| *P* | *CDE/c* | *MNS* |
| *Q* | *cDe* | *N* |
| *T* | *cDE* | *NS* |

Taking $R_z = m_S$, $R_1 = m_s$, $R_2 = n_S$ and $R_0 = n_s$, trial frequencies which may be found by Mourant's methods[3] may now be inserted into the formulæ given for the *MNS* system and corrections found so as to obtain the maximum likelihood estimates.

## Release of Histamine in Hepatectomized Dogs during Anaphylactic, Peptone and Tryptic Shock

It is well known that in dogs the liver is the main source of the histamine released during certain types of shock, such as anaphylactic and peptone shock[1]. However, shock can be obtained in hepatectomized dogs[2] and some evidence, particularly recent work by Feldberg and Schachter[3], indicates that under certain conditions tissues other than the liver release relatively large amounts of histamine.

I have found that histamine occurs in the blood of hepatectomized dogs during anaphylactic, peptone and tryptic shock. Studies have also been made of the blood coagulation time, the amount of platelets and the hæmatocrit during shock.

The histamine in blood was estimated according to Code's method. Hepatectomy was carried out by

Table 1. HISTAMINE RELEASE DURING SHOCK IN HEPATECTOMIZED DOGS

| Dog No. | Type of shock | Time (min.) | Blood clotting time (min.) | Hæmatocrit | Histamine (μgm./ml.) | Platelets* | Observations |

| 9 | Trypsin | 0<br>3 | 4·0<br>incoag. | 32<br>24 | 0·000<br>0·000 | 0·10<br>0·00 | Death 60 min. after injection |

* Given as c.c./100 ml. of blood. † 300 mgm./kgm. of Witte peptone. ‡ 3 mgm./kgm. of crystalline trypsin.

the Firor technique. Dogs were sensitized with horse serum by the Waters and Markowitz potassium alum method. Blood samples were taken from the carotid artery after hepatectomy and at 2–10 min. after the beginning of shock. Platelet volume was measured by the Van Allen thrombocytocrit. Table 1 summarizes the results of typical experiments for each type of shock.

In hepatectomized dogs, histamine is released in great amounts during peptone and anaphylactic shock. Considering Code's[4] observations for normal dogs, extra-hepatic release of histamine can explain the observed fall of blood pressure in hepatectomized animals during shock, although other depressor substances may be liberated as well. A rise of histamine in the blood was obtained in two out of eight hepatectomized dogs during tryptic shock. Death occurred frequently as a result of massive intravascular coagulation.

Hæmodilution was observed in almost all experiments during the first minutes of shock, in contrast to the classical hæmoconcentration observed during shock in normal animals. Hæmoconcentration occurred, however, in some hepatectomized animals after 30–60 min.

Increase of the blood-clotting time was the rule. In confirmation of other workers[5], fibrinolysis following blood coagulation was observed also in hepatectomized, shocked dogs, and the platelets decreased or disappeared from the blood.

## The Photonuclear Effect and the Complex Potential-Well Nuclear Model

THE recent success of the complex potential-well nuclear model applied to neutron and proton scattering from complex nuclei[1–3] led me to investigate this model for the photonuclear process.

The so-called 'giant resonance' for the photonuclear effect has long been known; however, of the most successful models[4–6] to date, that of Goldhaber and Teller[4], while explaining many of the general features of the $(\gamma,n)$ cross-section, fails to account in any detailed manner for the width of the resonance. On the other hand, the more detailed treatment of this general hydrodynamical model by Steinwedel and Jensen[5] does give the large resonance width only at the expense of the *ad hoc* introduction of a 'coefficient of viscosity' or damping coefficient. (A more serious defect of all these hydrodynamic, harmonic oscillator models is the theoretical prediction of similar 'giant resonances' at higher energies which, of course, have not been observed.)

The present work assumes that the incident photon is absorbed by one nucleon giving rise to one of two effects. In one of these the nucleon leaves the nucleus directly, carrying with it all the available energy (and angular momentum)—this can be termed the 'direct' effect. In the other, or 'indirect', effect, the nucleon is unable to escape with the total energy available and some sort of compound nucleus results which decays in the usual fashion. It is this latter process which may be thought of as being caused by the imaginary part of the potential, as this part represents the nuclear absorption.

Since the 'square' potential-well lends itself best to numerical computations, use has been made of it in which the potential is

$$\begin{aligned} V &= -V_0(1 + i\epsilon) \quad & r < R \\ &= 0 & r > R. \end{aligned}$$

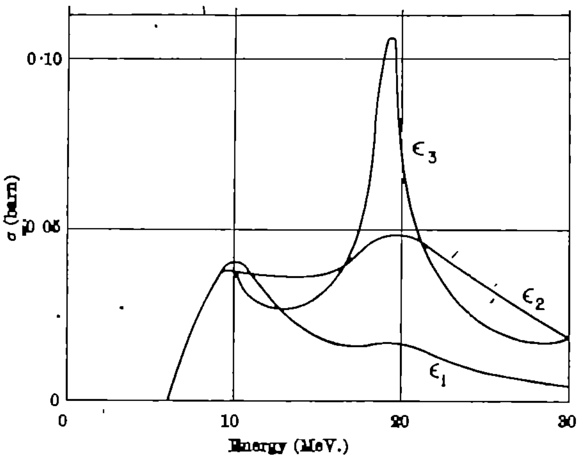

Fig. 1. The total photonuclear cross-section as a function of energy for three different forms of ε, the imaginary part of the square-well potential. For $\varepsilon_1$, $\varepsilon_2$, $\varepsilon_3$, ε is a constant (0·05), Gaussian, and linear with energy respectively

Feshback, Porter and Weisskopf[2] obtain a striking fit for neutron scattering of incident energy less than about 3 MeV. with ε constant and equal to 3 per cent; for 18-MeV. protons[3] ε is of the order of 25 per cent; while for high-energy neutron scattering ($\gtrsim$ 90 MeV.) values of 100 per cent or even higher seem necessary[7]. It thus seemed advisable to investigate the dependence of the (γ,*n*) cross-section on the form[8] of ε, and in this preliminary calculation three different forms of ε have been used:

$$\varepsilon = 0{\cdot}05 \qquad (1)$$

$$\varepsilon = 0{\cdot}330 \exp -(2{\cdot}473 - \hbar\omega/10)^2 \qquad (2)$$

$$\varepsilon = (1{\cdot}05\hbar\omega - 6{\cdot}58) \times 10^{-2} \qquad (3)$$

with $V_0 = 40$ MeV.; $R = 1{\cdot}40\ A^{1/3} \times 10^{-13}$ cm.; and $\hbar\omega$, the incident photon energy in MeV. The constants in (2) and (3) have been obtained by requiring ε to fit the values used in the initial neutron-scattering calculation[1] and in the proton-scattering calculations[3].

The results of a calculation of the total cross-section ($\sigma_d + \sigma_{ind}$) assuming an average nucleon binding-energy of 8 MeV. and with $A = 125$ are shown in Fig. 1. Only for the case where ε is linear with energy (labelled $\varepsilon_3$ in Fig. 1) does a marked resonance appear; however, none of the curves bears very close resemblance to the experimental photonuclear cross-sections in the neighbourhood of antimony.

Table 1 presents a comparison of the various parameters of the photonuclear cross-section curves for the different forms of ε, and also the experimental results of Montelbetti, Katz and Goldemberg[9] for antimony. Examination of the table also shows that the case of ε linear with energy most nearly approximates to the experimental values, even though the integrated cross-section is almost an order of magnitude too low. However, no further resonances appear at higher energies, as is shown by calculations above 30 MeV. (not shown in Fig. 1).

Table 1. COMPARISON OF SEVERAL PARAMETERS OF THE GIANT PHOTON RESONANCE FOR SEVERAL FORMS OF THE IMAGINARY PART OF THE SQUARE-WELL POTENTIAL, ε, WITH EXPERIMENTAL VALUES

| ε | Γ (MeV.) | $E_m$ (MeV.) | $\sigma_m$ (barn) | $\int_0^\infty \sigma dE$ (MeV.-barn) |
|---|---|---|---|---|
| Constant ($\varepsilon_1$) | 5·10 | 10·0 | 0·040 | 0·204 |
| Gaussian ($\varepsilon_2$) | 8·65 | 19·7 | 0·048 | 0·415 |
| Linear ($\varepsilon_3$) | 3·80 | 19·3 | 0·105 | 0·408 |
| Experimental (ref. 9) | 7·2 | 15·2 | 0·44 | 3·1* |

* Cross-section integrated to 23 MeV.

Further calculations are in progress and a detailed discussion of this model will be submitted for publication shortly.

This work was supported in part by the Campanha Nacional de Aperfeiçoamento de Pessoal de Nível Superior, and a summary of the results was presented before the VI Reunião Anual do Sociedade Brasileira para o Progresso da Ciência, Ribeirão Preto, S.P.

## Quantal Nature of the End-plate Potential

THE liberation of acetylcholine from the motor nerve endings in skeletal muscle is believed to take place in a quantal manner. The arrival of the action potential at the nerve terminals elicits the release of a number of packets of acetylcholine molecules of fairly uniform size, each of them producing a unit of depolarization in the post-synaptic membrane. This view is derived from the statistical analysis of the random step-wise fluctuations in the amplitude of successive end-plate potentials recorded from single neuromuscular junctions blocked by excess magnesium ions or lack of calcium ions[1]. The average magnitude of the steps was found to be identical with the mean size of the miniature end-plate potentials recorded from the same junction and due to the spontaneous extrusion of single acetylcholine quanta from the resting nerve endings.

At ordinary room temperature all the acetylcholine packets released by one nerve impulse act practically simultaneously on the end-plate membrane. Therefore the end-plate potential resulting from the sum of a number of units has usually a smooth rising phase, even in preparations blocked by magnesium ions, where the quantum content of the response has been considerably decreased. Sometimes, however, the rising phase shows notches that indicate a small degree of asynchronism in the liberation of the units (cf. Fig. 3, $C_1$ of ref. 1). It has been found that lowering the temperature greatly accentuates these discontinuities. In extreme cases the leading edge of the end-plate potential is made up of a number of steps arising with slightly different, and apparently random, latencies after the stimulus artefact. This is clear in the records shown in Fig. 1. They illustrate in a simple way the quantal nature of the process of neuromuscular transmission.

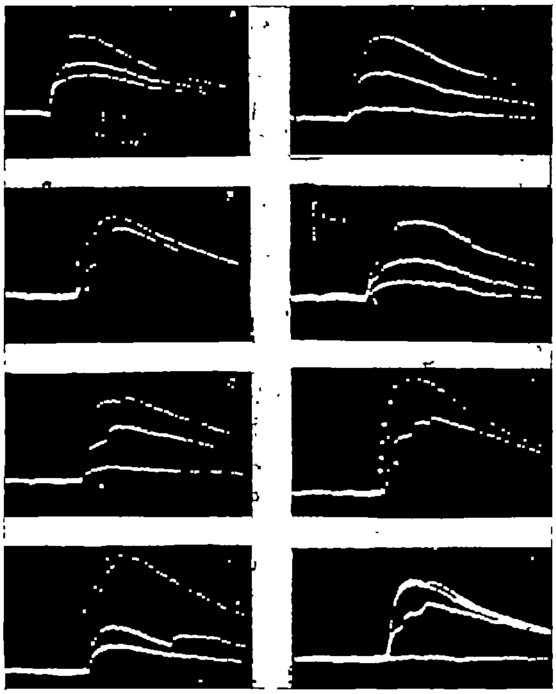

Fig. 1. End-plate responses of single neuromuscular junctions of the M. ext. l. dig. IV of the frog recorded with intracellular micro-electrodes. The Ringer's fluid contained 15 m.mole/l. of magnesium in order to block transmission and $10^{-6}$ prostigmine to increase the size of the unit response. All the records were taken at 6·3° C., except *B* (5° C.) and *F* (9·4° C.). The voltage calibration of *A* applies to all records but *F*. Time calibration is the same for all the records. The rising phase of the end-plate potential, normally smooth, is made up by steps the positions of which are marked by arrows in some of the records

Below about 10° C. some degree of asynchronism was observed in most of the end-plates examined. As the release of acetylcholine is caused in some way by the nerve action potential, the time course of which lengthens as the temperature is lowered, one may assume that the period during which transmitter quanta can leave the nerve terminals would also become longer at lower temperatures. The chances of observing random delays between the release of different units would, therefore, become greater.

The differences existing among end-plates of the same muscle examined at constant temperature seem to indicate that morphological or 'geometrical' factors have some influence on the asynchronism of the end-plate response. For example, one might expect small differences in the time of arrival of the action potential at different spots of the nerve terminals at which the release of the transmitter can take place.

The possibility had to be considered that the steps in the end-plate potentials might be due to a multiple innervation of the end-plate. It is known that end-plates of the frog muscle may receive innervation from two or more axons[2]. If these fibres have different diameters, and in consequence different thresholds and conduction rates, the end-plate potential may show two or more steps depending on the stimulus strength (Castillo and Katz, unpublished observations). In the present experiments, however, no evidence of such multiple innervation could be obtained when the intensity of the nerve stimulus was varied.

## An Interference Optical Alinement Method

An interference method for the centring of optical systems with one and two surfaces has been described by Harle[1]. In the same paper, a number of principles applicable to more general alinement problems were enunciated. In the present communication, the extension of these principles to the alinement of co-axial optical systems with a large number of surfaces is discussed.

In applying interferometry to the alinement of co-axial optical systems, the spatial distribution of non-localized interference patterns is utilized. Thus the necessity of image location is eliminated and a technique combining the advantages of aperture sight and image alinement methods is provided.

The general optical arrangement is shown in Fig. 1. Light from a coherent source *A* forms an interference pattern distributed spatially in the axial direction of the components to be alined, *C*. Observation of the fringe pattern is made in one of an infinite number of planes of observation *B*. Then, since the interference pattern observed is, in effect, an image of the fringe pattern, real or virtual, formed in a plane conjugate to *B*, alinement may be achieved by arranging the components *C* in turn, in a selected order, until the centres of the direct and the secondary fringe patterns, as observed with the viewing microscope *D*, are coincident in the plane *B*. For alinement by reflexion, the transmission arrangement is modified as shown in the dotted portion of Fig. 1. Here, a reflecting surface is included as a component of *C*, and light from a half-reflecting mirror *E*, designed to give no displacement of the transmitted light-path, is directed to a new plane of observation $B^1$.

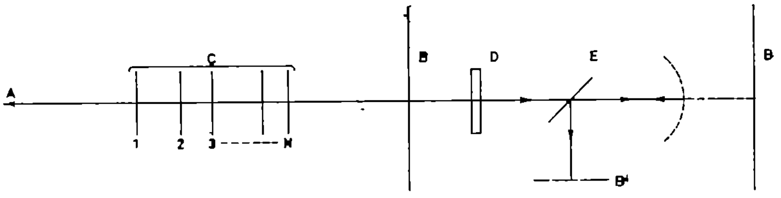

Fig. 1

For each class of observation, the interferometer requirements are in principle the same. In the first instance, the fringes must be distributed spatially in the direction of alinement. Secondly, the intensity distribution of the fringe pattern must be sufficiently sharp to permit precise detection of the centre fringe displacement.

Several interferometers, which are adaptations of well-known interferometer arrangements, have been developed for this purpose. The first of these utilizes a bi-prism and slit. The components of *A* thus produced are displaced laterally with regard to the axis of alinement and straight-line fringes result. For alinement in two dimensions, rotational methods or a double bi-prism having two individual prisms crossed at right angles and a cross-shaped slit of the same orientation are used. The resultant fringe pattern appears in the form of a series of cross-shaped fringes. For both arrangements a white-light source is required to identify the centre fringe. A second instrument employs a point source and the Michelson interferometer with its mirrors adjusted for parallelism. The components of $A$ are now displaced in the axial direction of the system, and the resultant fringes are circular in nature with an intensity distribution resembling that of similarly shaped localized Michelson fringes. This arrangement eliminates the necessity of identifying the centre fringe. In an improved version of the apparatus, the Michelson interferometer is dispensed with and a Fabry–Perot étalon substituted. The fringes produced, which are now much sharper and of the multiple-beam variety described by Tolansky[2], permit increased precision of alinement.

The theory of the method is similar to that of the image alinement method, in which an object is moved to a series of mechanically alined positions in planes conjugate to $B$. Now, however, the errors due to mechanical alinement are eliminated. The interference method therefore yields, as well as a high operational convenience, a previously unattained precision when any reasonable number of components are alined. In the experiments performed, alinements of as many as twenty components to a common axis have been made. Moreover, the component surfaces need not be surfaces of revolution and may include asymmetrical arrangements such as sphero-cylinders and torics. Such cases are characterized by different fringe magnifications in different meridional planes.

Details of this work will be published in full elsewhere. Accounts of applications of the method in a number of related fields of investigation will also appear in due course.

## Brightening of the Solar Limb in the Far Ultra-Violet

DURING an eclipse of the Sun, the obscuration of the disk causes a corresponding fall in the electron density in the lower layers of the ionosphere. This fall, and the subsequent recovery, have recently been used to locate the sources of ionizing radiation which were responsible for the electron production in the *E*- and *F*1-layers during the eclipse of February 25, 1952, in Central Africa[1]. At this epoch the level of solar activity was fairly high, and it was found that 36 per cent of the total ionizing radiation was emitted near the east and west limbs from well-defined sources which were additional to the uniform background radiation from the disk. These sources coincided in position quite closely with areas from which the coronal line at 5303 A. was emitted strongly, and they were assumed to be associated with short-lived centres of chromospheric activity. Their intensities were so great that any permanent limb brightening which may have existed at the time would have been masked unless it was very pronounced.

The eclipse of June 30, 1954, coincided with a period of extremely low solar activity, and the astronomical data suggest that the Sun's disk was almost completely devoid of any features indicating the existence of even local centres of activity. Measurements of electron density were made at Inverness and Slough, about 700 km. apart, and the detailed correlation between the changes which were observed in the *E*- and *F*1-layers strongly suggests that the locations of the respective sources of ionizing radiation must have been the same for both layers. Methods of analysis similar to those described earlier[1] have been used; but, in spite of the absence of any visible centres of solar activity, only 92 per cent of the ionizing radiation can be accounted for in terms of a uniformly radiating disk.

The locations and relative intensities of the residual sources cannot be determined very accurately because of small anomalies in the behaviour of the ionosphere and also because the recombination coefficients of the layers are not accurately known. However, for both the *E*- and *F*1-layers at Inverness and at Slough, the experimental evidence points to the existence of brightening of the limb near the equator and darkening of the limb at the poles, extending in both cases over arcs of 40°–60°. It is also necessary to assume the existence of a small bright spot at $P = 255°$, $r = 0 \cdot 95\, R_{\odot}$, and in this connexion it is interesting to note that faint coronal radiation at 5303 A. was observed on the same day by Müller[2] in the arc $P = 232°–247°$.

The provisional locations and relative intensities of the sources controlling the *E*- and *F*1-layers are given in Table 1. Although the radiation in question is in the far ultra-violet, it may be significant that a similar intensity distribution has been reported recently by Christiansen and Warburton[3] for solar radio noise on 21 cm.

Table 1. SOURCES OF *E*- AND *F*1-LAYER IONIZING RADIATION, JUNE 30, 1954

| Source | Position angle ($P$) | | Intensity (per cent) both stations |
|---|---|---|---|
| | Inverness | Slough | |
| Disk | — | — | +92 |
| W. limb | 240–280 | 240–300 | + 6 |
| E. limb | 60–120 | 60–120 | + 4 |
| N. pole | 330– 30 | 330– 30 | − 2 |
| S. pole | 150–210 | 150–210 | − 4 |
| Spot | 252<br>$r = 1 \cdot 0\, R_{\odot}$ | 258<br>$r = 0 \cdot 9\, R_{\odot}$ | + 4 |
| | | Total | 100 |

$P$ = degrees east from the north point; $R_{\odot}$ = radius of photosphere

In view of the unusual quietness of the Sun during this eclipse, it seems possible that the observed departures from a uniformly radiating disk may be a permanent feature and that they indicate brightening of the limb near the equator equal to about + 5 per cent and darkening of the limb near the poles equal to about − 3 per cent of the total radiation. If the isolated bright spot is assumed to be a temporary feature, the permanent uniform disk radiation contributes 96 per cent of the total.

## Sensitivity of Alpha- and Beta- Lead Azide

LEAD azide, $PbN_6$, exists in two allotropic forms[1,2], one (α) orthorhombic and the other (β) monoclinic. α-Lead azide is readily prepared by mixing in the normal way solutions containing azide and lead ions; β-lead azide crystallizes as needles when aqueous solutions of sodium azide and lead nitrate inter-diffuse slowly[1]. Table 1 summarizes the crystallographic relations[1,3]. Both forms are explosive and α-lead azide is in common use as a detonator. It is said[1,2] that β-lead azide is much more sensitive and dangerous than α-lead azide.

Table 1. PROPERTIES OF THE TWO CRYSTALLINE MODIFICATIONS OF LEAD AZIDE, $PbN_6$

| Species | Unit cell size and shape (A.) *a* | *b* | *c* | No. of molecules in unit cell | Enthalpy of formation $\Delta H_f$ (kcal. gm.mole$^{-1}$) |
|---|---|---|---|---|---|
| Orthorhombic α-$PbN_6$ | 6·628 | 11·312 | 16·246 | 12 | 115·5 |
| Monoclinic ($\varphi = 90° 10'$) β-$PbN_6$ | 5·090 | 8·844 | 17·508 | 8 | 115·8 |

In the course of extensive studies of azide thermochemistry (to be published), the standard heats of formation of both explosive and non-explosive azides have been measured. A strong correlation between the heats liberated on explosive decomposition on one hand, and both sensitiveness to impact or friction and speed of detonation[4] on the other, has been found[5]; there is no similar correlation of heats of decomposition with speed or ease of slow thermal decomposition. Although it has not been possible to assess sensitiveness to impact or friction in completely satisfactory terms, and although true detonation velocities have still to be measured with precision, the principal reason why this simple correlation has not been stressed hitherto is the very unreliable nature of previous thermochemical data.

It was thought interesting to examine the thermochemistry of the two forms of lead azide and to ascertain whether β-lead azide is thermodynamically less stable than α-lead azide. The standard enthalpy of formation of crystalline α-lead azide was found to be + 115·5 kcal. mole⁻¹ from a precipitation experiment[5]. Determination of the heat of formation of β-lead azide in this way is not possible. To derive this quantity an electrical method was devised in which the changes of the thermodynamic functions in the reaction (1) could be measured:

$$\alpha\text{-PbN}_6(\text{cryst}) \rightarrow \beta\text{-PbN}_6(\text{cryst}) \qquad (1)$$

Two cells, *A* and *B*, were constructed with lead amalgam – lead azide electrodes and sodium azide electrolyte. The reproducibility of metal–metal azide (including both Pb-$PbN_6$ and Ag-$AgN_3$) electrodes has been well established[6]. In cell *A* the two electrodes lead-α-lead azide, lead-β-lead azide were connected by a sodium azide (*M*/10) salt bridge; in cell *B*, by a pair of silver–silver azide electrodes back-to-back:

Cell *A*: $\overset{-}{\text{Pb}} \mid \alpha\text{-PbN}_6 \mid \text{NaN}_3 \mid \beta\text{-PbN}_6 \mid \overset{+}{\text{Pb}}$.

Cell *B*: $\overset{-}{\text{Pb}} \mid \alpha\text{-PbN}_6 \mid \text{NaN}_3 \mid \text{AgN}_3 \mid \text{Ag} \mid \text{AgN}_3 \mid \text{NaN}_3 \mid \beta\text{-PbN}_6 \mid \overset{+}{\text{Pb}}$

At 25° C. both cells gave an electromotive force $E = 0·0136$ V.; thus for reaction (1), $\Delta G = 314$ cal. mole⁻¹. The temperature coefficient of the electromotive force was zero within the limit of experimental error ($dE/dT$) $< 10^{-5}$ V. deg.⁻¹, corresponding to $\Delta S < 0·23$ cal. deg.⁻¹. These values lead to an enthalpy change for reaction (1) of $\Delta H \sim 0·30 \pm 0·05$ kcal. mole⁻¹, and the value 115·8 kcal. mole⁻¹ for the enthalpy of formation of β-lead azide. Over a period of several days, especially at higher temperatures, the e.m.f. of the cells at 25° C. diminished slowly from the initial value, probably owing to the slow growth of α-$PbN_6$ at the β-electrode. For this reason very precise values of $dE/dT$ and $\Delta H$ were difficult to obtain.

The difference, 0·3 in 115·5 kcal. mole⁻¹, in enthalpies of formation is very small compared with the differences between other azides of differing sensitivity[5]. This result, together with the fact that β-lead azide gave no trouble in manipulation, raises doubts about the much greater sensitiveness it is said[1,2] to possess. A re-examination of its behaviour during mechanical initiation of explosion, and a redetermination of its detonation velocity would be valuable.

## Unit-Cell Dimensions of γ-Lauric and γ-Myristic Acids

Thibaud and Dupré La Tour[1] discovered the polymorphism of the fatty acids and observed that only in the case of myristic acid did the γ-form appear, and that infrequently after recrystallization of this acid at 0° C. This form was characterized by a 'long spacing' of 37 A., and could be converted to the more common α-form by heating to within a few degrees of its melting point.

Samples of α-lauric acid and α-myristic acid were stored in this laboratory for a period of two years at room temperature and were then ground prior to taking their X-ray powder diffraction photographs. The lauric acid had changed to a different form but the myristic acid was still in the α-form. However, after standing for a further few days in the ground state, the myristic acid also had become transformed to a new structure giving a diffraction pattern almost identical to that of the transformed lauric acid. This new form is thus the stable one at room temperature, although the α-form is normally obtained on recrystallization both from solvents at room temperature and from the melt.

The diffraction patterns of the new form are unusual in that no 'long spacings' are immediately apparent, as they are on the diffraction patterns of all long-chain aliphatic compounds previously studied. The absence of these spacings makes the interpretation of the powder patterns difficult but, by a slight modification of Vand's[2] method, the photographs were indexed and the unit cell dimensions determined. For lauric acid $a = 22·1 \pm 0·1$, $b = 5·24 \pm 0·05$, $c = 32·0 \pm 0·1$ A., $\beta = 99° 58'$, $\alpha = \gamma = 90°$, observed density $= 1·09 \pm 0·01$ gm./cm.$^{-3}$, calculated density 1·09 gm./cm.$^{-3}$ (assuming twelve molecules per unit cell). For myristic acid $a = 22·2 \pm 0·1$, $b = 5·14 \pm 0·05$, $c = 37·2 \pm 0·1$ A., $\beta = 100° 50'$, $\alpha = \gamma = 90°$, calculated density 1·09 gm./cm.$^{-3}$ (assuming twelve molecules per unit cell). The transformed myristic acid has a 'long spacing' ($c \sin \beta$) of 36·5 A. and is easily reconverted to the α-form by heating to within a few degrees of its melting point, and so is identified with Thibaud and Dupré La Tour's γ-form.

The distance between alternate carbon atoms in the plane zig-zag hydrocarbon chain in α-lauric acid is 2·52 A.[3], while the corresponding distance in potassium laurate is 2·59 A.[4]. It is thus to be expected that a myristic acid molecule will be longer than a lauric acid molecule by between 5·0 and 5·2 A., depending on its crystallographic environment. The difference in length of the $c$-axis in the two acids is 5·20 A. and the difference in long spacing is 5·00 A., so that in the γ-form the molecules must lie approximately parallel to the $c$-axis of the cell, that is, approximately perpendicular to the (001) plane. With such large unit cells, the indexing of the powder photographs is ambiguous except for a relatively small number of reflexions, so that the detection of systematic absences is difficult and uncertain. However, on both photographs it appears that $\{h\,0\,l\}$ reflexions with $(h + l)$ odd are absent. The probable space group of the γ-form is thus either $Pn$, $P2/n$ or $P2_1/n$.

## Rainfall and Biennial Bearing in Tung (*Aleurites montana*)

Examination of past records of yields of tung trees and rainfall in corresponding periods has given rise to a hypothesis to explain the cause of biennial bearing, to which this crop is prone.

Harvesting of the tung crop in Nyasaland begins about May of each year, and for six consecutive harvests up to 1954, an alternating rhythm of high and low yields was produced. Had the biennial rhythm been maintained, the tung crop due to be harvested in 1955 would have been low; but field observation on immature fruit predicts that the crop will in fact be on the high side and the rhythm broken.

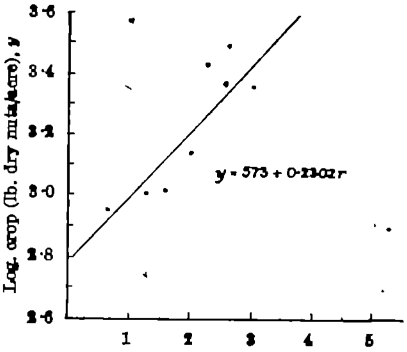

Fig. 1. Response of subsequent yield per acre to rainfall at flower primordial stage. Correlation coefficient, rain/yield, is + 0·8421 ($P = 0·01$, $P = 0·001$)

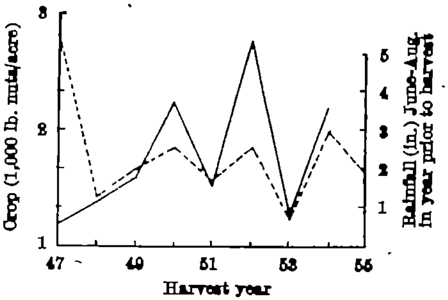

Fig. 2. Seasonal sequence of rainfall at flower primordial stage and subsequent crop. ———, yield; – – – –, rainfall

An examination of rainfall totals coinciding with various stages of the growth sequence, and subsequent crop data taken from one field at the Tung Experimental Station, yielded no significant correlation coefficients for any of the following stages: (*a*) rainfall for the sixteen months period from initiation of flower primordials to fruit maturation; (*b*) rainfall for the period of flower opening and pollination correlated with the resulting crop; (*c*) rainfall during period of fruit-set and the resulting crop; and (*d*) rainfall during fruit maturation period correlated with the resulting crop.

However, a positive correlation coefficient of + 0·8421 between total rainfall for the months June–August and crop for the following year reaches significance between $P = 0·01$ and $P = 0·001$. The rainfall for this period refers to the time at which flower primordials are being formed and is between nine and twelve months before the resulting crop is harvested. The correlation is illustrated in Figs. 1 and 2.

The poor correlation with the 1946 rain and 1947 crop can probably be explained by the fact that the tung had not yet come into full bearing. The rainfall for June–August 1954 totalled 1·93 in., which is the mean for the period under review; thus the crop to be harvested in 1955 may be expected to be rather more than the mean for previous years, taking into account the increased age and size of the trees.

## Photo-reactivation of *Botrytis fabae* Sardiña measured by a Local-lesion Technique

WHEN leaves of broad bean (*Vicia faba* L.) are sprayed with suspensions of spores of *Botrytis fabae* Sardiña they develop chocolate-coloured lesions[1]. By rubbing suitably diluted spore suspensions over the upper surfaces of leaves of the variety Seville Longpod with the forefinger, and then keeping the inoculated plants at about 20° C. in a saturated atmosphere, we find that the discrete lesions are uniformly distributed and, after 24 hr., can be easily counted. The lesions provide an assay method comparable with counting the local lesions that are produced in plants by many viruses, and we have used them to measure how ultra-violet radiation affects the infective capacity of the spores.

Ultra-violet radiation, more than 95 per cent of wave-length 2537 A., was provided by a Hanovia XII lamp. Spore suspensions (0·3 ml. samples contained in cavity slides) were exposed at 40 cm. from the lamp, where the radiation intensity was 173 μW. per sq. cm. After exposure for various times, the irradiated suspensions were inoculated to halves of bean leaves, the opposite halves of which were inoculated with unirradiated spores, and the plants were then placed in a saturated atmosphere and kept in darkness for 24 hr. In these conditions, about 90 per cent of the original infectivity of the spore suspensions was destroyed by exposure for 3½ min. to the radiation. The spores of *B. fabae* are multinucleate and the rate of inactivation did not correspond to a first-order reaction (that is, it is a so-called 'multiple-hit' curve).

In studying the rate of inactivation, inoculated plants were kept in the dark because the effects of ultra-violet radiation on some biological systems can be mitigated if the systems are later exposed to visible light, a phenomenon that has been called photo-reactivation[2]. For example, when irradiated suspensions of bacteria or some fungi are cultured on agar in the light, more grow than if the cultures are kept dark. Similarly, irradiated preparations of some viruses[3,4] can be photo-reactivated; but with these the phenomenon does not occur if the viruses are exposed to light *in vitro*, but only when infected host cells are illuminated. No previous tests seem to have been made to see whether the pathogenicity of irradiated fungi is influenced by visible light, and we have therefore made some with *B. fabae*. Table 1 records the results of two experiments in which spores were irradiated for 3½ min., and then exposed to light for 0, 2, 4 or 8 hr., before all lots were inoculated to plants 8 hr. after irradiation. Plants with four sets of paired leaves were inoculated, and the different treatments were arranged on half-leaves in a 4 × 4 latin square design. Half the inoculated plants were then placed in daylight and half in darkness.

The half-leaves inoculated with spores exposed to visible light produced more lesions than those inoculated with spores kept for 8 hr. in the dark, and the magnitude of the difference usually increased with increases in the length of time the spores were exposed to light. Regardless of the time of exposure to light before inoculation to plants, plants kept in daylight after inoculation always produced significantly more lesions ($P > 0{\cdot}01$) than those kept in darkness (for statistical analyses[5], the numbers of lesions, $n$, were transformed to $\log (n + 10)$). As plants inoculated with unirradiated spore suspensions produce the same numbers of lesions whether they are kept in the light or dark, this increase with irradiated suspensions when inoculated plants were in the light is again attributable to photo-reactivation. The results show that some spores can still be photo-reactivated after 8 hr. in darkness, and they suggest that spores on the leaves of a host respond more readily to light than when they are *in vitro*, for the inoculated plants were in daylight for only about three hours.

Table 1. EFFECTS OF DIFFERENT LENGTHS OF DAYLIGHT ON THE INFECTIVITY OF ULTRA-VIOLET IRRADIATED SPORE SUSPENSIONS OF *Botrytis fabae* (SARDIÑA)

| Post-inoculation treatment (hr. in daylight after ultra-violet treatment) | Mean lesion count/half-leaf | | | | |
|---|---|---|---|---|---|
| | 0 | 2 | 4 | 8 | Mean |
| Exp. 25 | | | | | |
| Plant in darkness | 20 | 105 | 204 | 185 | 100 |
| Plant in daylight | 214 | 426 | 407 | 480 | 362 |
| Exp. 27 | | | | | |
| Plant in darkness | 25 | 46 | 105 | 194 | 93 |
| Plant in daylight | 50 | 145 | 241 | 397 | 208 |

As with other biological systems, the amount of photo-reactivation increases with increasing amounts of exposure to ultra-violet radiation. After exposure for 4½ min., the ratio of numbers of lesions on plants in the light to those in dark was 1½ times as great as after exposures for 3½ min.

## Physiological Races of *Puccinia polysora* Underw.

OUR early studies on the resistance of maize seedlings to this rust in East Africa led to the hypothesis that a dominant major gene controls the hypersensitive type of resistance[1]. During the past two years, we have bred many lines of maize that are pure for this gene, by selfing resistant plants selected from Central American types and by selfing first crosses between resistant Central American types and East African susceptible types. In seedling-inoculation experiments, variation occurs in the manifestation of the hypersensitive reaction, from necrotic lesions without development of sori (up to eighteen days) to necrotic lesions with well-developed small sori. On a system of recording based on, but modified from, that employed by the wheat breeders (see ref. 2), we have classed the former as 01 (no sori) and the latter as 1 (small sori), the fully susceptible reaction, with large sori and little or no surrounding chlorosis, being class 4.

From the start of this work we had in mind the possibility that more than one physiological race of *P. polysora* might exist in East Africa. Collections of uredospores were made in three separate regions—

Zanzibar, Northern Tanganyika and Uganda. Each was established in a separate glasshouse and has been so maintained since; although owing to the great production of spores and the movement of attendants between houses we cannot be sure that contamination has not occurred. Every maize family tested in the course of our breeding studies has been inoculated in two and usually all three houses. Through nearly two years and 1,600 family tests, the reaction of each individual maize family was identical, within the expected errors of experiment, in each house.

The position at the end of 1954 was therefore that we had no reason for thinking that more than one physiological race of *P. polysora* had become established in East Africa. This was supported by observations on our maize lines when tested during 1953 and 1954 in the field, in such widely separated sites as southern Tanganyika and Uganda; in general, the field behaviour corresponded with the juvenile reactions recorded in our glasshouses.

Table 1

| Origin of maize lines | No. of separate families tested | Juvenile reaction to original race | Juvenile reaction to new race |
|---|---|---|---|
| Selfs of AFRO 29 (Colombia 2) | 3 | Class 01 | Class 4 |
| Second selfs from cross, AFRO 29 × Katumbili | 2 | Class 01 | Class 1 |
| Second selfs from cross, AFRO 29 × Durum | 2 | Class 01 | Class 4 |
| Self of AFRO 250 (Amarillo Caryotepe ex Nicaragua) | 1 | Class 01 | Class 4 |

In January 1955, however, during routine testing of certain maize lines in our glasshouses, we obtained a reaction strongly suggesting a mixture of two physiological races of the fungus; the expected hypersensitive lesions were interspersed with a few large sori characteristic of full susceptibility. Isolations were made from the large sori and the suspected new race established. The new race was then inoculated to a number of maize lines known to behave uniformly to the original race; and simultaneous control inoculations with original-race spores were made.

In the course of these experiments we encountered some anomalies that require further study. A number of pure lines gave identical reactions to both races of the fungus. In Table 1 are shown results of experiments in which a clear differential reaction has been recorded.

The conclusion that a new race of *P. polysora* has appeared in our glasshouses seems inescapable. How it has arisen cannot be decided; but since the nearest known field occurrence of this rust is more than a hundred miles from Muguga and no newly collected material has been introduced into our houses for more than two years, it is unlikely that the new race has accidentally entered our houses from outside.

## A New Method for counting Live and Dead Bull Spermatozoa

When bull semen is diluted in a buffered (pH 7·0) solution of sodium chloride which is isotonic with bull seminal plasma (Δ, − 0·54° C.) and is filtered through a layer of small glass balls, the dead spermatozoa are retained by the filter while live ones pass through; it is therefore possible to estimate the percentage dead spermatozoa in bull semen by comparing the opacity of diluted semen before and after filtration.

Estimations were made on twenty-six untreated samples of bull semen and on three samples which contained different proportions of killed spermatozoa. The spermatozoa were killed by rapidly pipetting semen at 37° C. into tubes pre-cooled to 5°, 0° and − 10° C.

For filtration, the semen was diluted by adding a few drops (0·1–0·2 ml.) of semen to 20 ml. buffered saline. In the test, 10 ml. of the suspension was pipetted gently on to the dry filter bed and the entire filtrate used for measurement. The filter bed consisted of 1·0 ml. dried acid-washed glass balls ('Ballotini', Chance Bros.; mean diameter, 200μ); these were held in place in a 1½-in. filter funnel by a single large glass ball (5 mm. diameter). The upper surface of the filter bed was protected by a thin layer of large glass balls (3 mm. diameter) so that the bed was not disturbed when the suspension was poured on to it. The optical density of the suspensions before and after filtration was measured in a Spekker photometer (Hilger and Son) in 1-cm. cuvettes.

Estimates of the proportions of dead spermatozoa in undiluted semen were made by counting the number of eosinophil spermatozoa in a total of a hundred spermatozoa from each of two smears stained with nigrosin-eosin[1].

Statistical analysis shows a highly significant correlation ($r = 0·7$; $p < 0·001$) between the percentage eosinophil spermatozoa and the percentage difference in opacity between filtered and unfiltered portions of the same sample of semen; the analysis was made by Dr. R. C. Campbell, A.R.C. Unit of Reproductive Physiology and Biochemistry, Cambridge.

Further, microscopical examination showed that the proportion of motile spermatozoa was uniformly greater in the filtrates than in the unfiltered suspensions.

Because a relationship is known to exist between the proportion of dead spermatozoa in bull semen and its fertility[2], we believe that the technique we have described may form the basis of a practical test for the evaluation of bull semen used for artificial insemination.

We are grateful to Mr. L. E. A. Rowson, Cambridge Cattle Breeders, Ltd., for supplies of bull semen.

## Lunar Rhythm in the Emergence of an Ephemeropteran

In a paper published in 1927, Hora[1] suggests that the swarming of some Ephemeroptera is related to the lunar cycle. Evidence has been obtained which suggests that *Povilla adusta* Navas, a mayfly widely distributed in Central and Southern Africa, shows uch a rhythm of emergence in Uganda. The interest of this lies in the fact that very few examples are known of lunar rhythms in non-marine animals (see Caspers[2]).

It was suspected late in 1953 that adults (subimagines and imagines) of *Povilla adusta* appeared in large numbers only at about the period of full moon, and analysis of the dates of twenty-two swarms observed between March 1953 and April 1955 at Kaazi (twelve miles from Kampala) and Jinja, both on Lake Victoria, and on Lake Albert, shows that such swarms only occurred within five days of full moon, with the greatest number of swarms on the second night after full moon Fig. 1). On three occasions swarms were recorded simultaneously at Jinja and Kaazi, which are fifty miles apart.

The adults come to light between 7.30 and 9.30 p.m. (East African Standard Time) and are not seen at other times: individuals only live for about one hour. A light-trap technique was therefore used when sampling at Kaazi during August 10–21, 1954. Of the 1,521 specimens obtained on these twelve nights, 680 (44 per cent) came on the second night after full moon (Fig. 2).

Examination of the specimens in the British Museum (Natural History) showed that fourteen specimens (some dating from 1900) were labelled with the date. Analysis of these dates and of the dates of three specimens recorded by Navas[3] relative to full moon showed a different distribution in which there was no marked peak, which may perhaps be attributed to the following circumstances: (1) The records are of single specimens (except for one record from Lake Albert which relates to a swarm on the fourth night after full moon), and thus do not necessarily correspond to the peak emergence period. (2) The specimens are from localities ranging from 17° S. to 11° N.: it is possible that a lunar rhythm is only maintained near the equator, where the annual variation in day-length and temperature is low. The evidence for this is very meagre but, of the eight specimens the dates of which fall outside the full-moon emergence period of eleven days, only one was caught in the field within 5° of the equator.

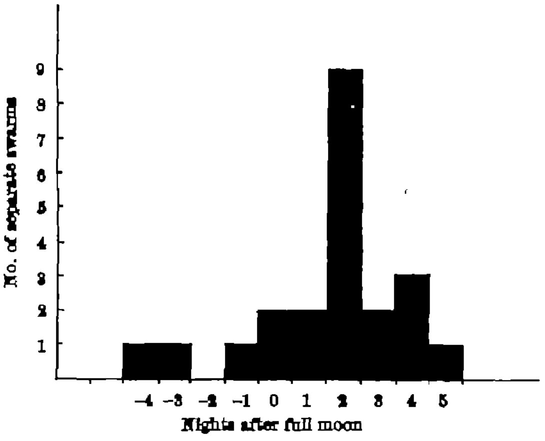

Fig. 1. Dates of twenty-two *Povilla* swarms relative to full moon

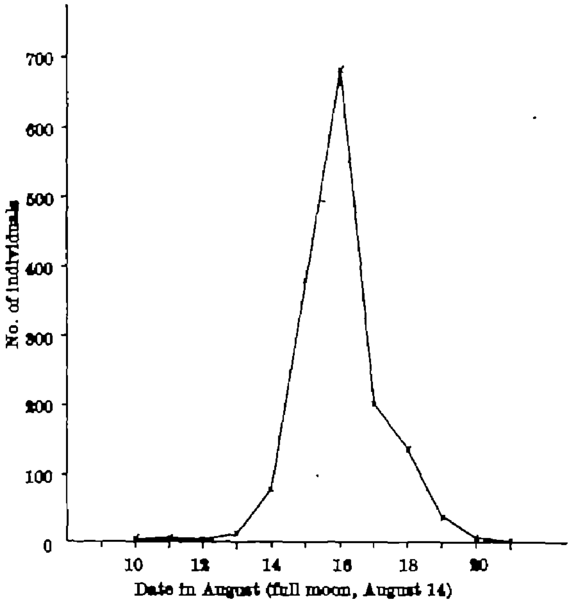

Fig. 2. Numbers of *Povilla* adults caught at Kaazi relative to full moon

Experimental work has been limited by the difficulty of keeping larvæ in the laboratory for more than two or three weeks, but some interesting results have been obtained and further work is in progress.

It has been found that the larvæ show a marked diurnal rhythm, remaining in their burrows during the day and swimming freely at night. This rhythm is maintained in darkness for at least two weeks.

Twelve adults have emerged in the laboratory from larvæ kept under various lighting conditions. Eight of these emerged within three days of full moon. Two emerged seven days before full moon when the aeration supply broke down. The remaining two individuals emerged eleven days before full moon, possibly having been influenced by being collected in the field the previous day.

I am indebted to Dr. P. S. Corbet, of the East African Fisheries Laboratory, Jinja, for his observations made on Lake Albert and at Jinja, some of the latter in conjunction with Mr. A. Tjönneland, of the Zoological Laboratory, University of Bergen.

## Placentation in the Adder, *Vipera berus*

Placentation has been described in a number of viviparous lizards and snakes, but has not been previously reported in the adder.

The relationships between the extra-embryonic membranes and the maternal tissues have been studied in five adders taken in the later stages of pregnancy. In each case the histological appearances suggest that a placenta is present. The chorio-allantois, which contains large patches of vacuolated tissue, is thrown into numerous villi. The oviduct is also villous, and the maternal and fœtal villi interdigitate. Both contain capillaries. The oviducal epithelium is thinner at the placental site than elsewhere; it is also thinner than it is in non-pregnant specimens. Between the fœtal and maternal tissue there is a thin fibrous membrane which is probably an egg-membrane, for it completely surrounds the embryonic and extra-embryonic structures.

From this preliminary survey it appears that the condition in the adder agrees fairly closely with that described by Weekes[1] as her type III of reptilian chorio-allantoic placentæ.

Little critical work has been done on the functions of the placentæ of reptiles. Weekes suggested that certain types of reptilian placentæ are mainly respiratory organs, others supply water to the embryo, whereas the most specialized (type III) have a nutritive function. More recently, Clark *et al.*[2] have suggested that some amino-acids pass across the placenta to the embryo in the snake *Thamnophis sirtalis*.

Weekes claimed that chorio-allantoic placentæ in reptiles are invariably associated with relatively small-yolked eggs. This, however, is not the case in the adder, where the amount of yolk is large, being comparable with that in the oviparous grass snake, *Natrix natrix*. Furthermore, all the yolk in the adder is not utilized during development, since the yolk-sac is still substantial at the time of parturition, representing some 8 per cent of the body-weight of the embryo.

Work in progress shows that the yolk-sac, which is retracted into the body-cavity at birth, provides a source of energy for the young adder during its first eight months or so of life. After birth in the early autumn, the young snakes undergo about four weeks of activity followed by hibernation until the spring. They can, and probably always do, survive for the whole of this period without feeding. Indeed, it has been shown experimentally (Griffiths, I., and Smith, M. A., work in progress) that the yolk-sac can provide enough nourishment for up to seven months of continuous activity.

It seems, therefore, that in the adder the yolk-sac has taken on a post-partum function. It is suggested that this has been rendered possible by the transfer of some of the prenatal functions of the yolk-sac to the chorio-allantoic placenta. The relative roles of the yolk-sac and placenta during embryonic life are now being investigated.

## Skull Development in Chick Embryos after Ablation of One Eye

THERE is in birds a thin vertical plate of bon between the eyes known as the interorbital septum In the chick embryo this originates from the fusion c two pairs of cartilaginous primordia (the orbita cartilages above and the trabeculæ cranii below) with each other and with a median cartilaginous bar, th intertrabecula. At around seven to eight days o incubation, these structures lose their identities and merge into one another to form the high thin septum of the fully formed chondrocranium. At about th same time the lateral unfused parts of the anterio orbital cartilages regress and disappear almos completely.

The skull in animals such as the chick, where th trabeculæ fuse between the orbits and contribute t an interorbital septum, are termed tropitrabic. This condition, at least as it is seen in birds, has been correlated with the relative proportions of the eyes and brain at mid-orbital level, and especially with the large size of the former[1]. It therefore seemed possible that the developing eyes might exert some influence, mechanical or otherwise, on the form of the cartilaginous skull.

Ablation of one eye was carried out through a window in the egg-shell after two or three days incubation, either by dissection or by the use of a hot needle. The window was then covered with adhesive cellulose tape and the eggs incubated for varying periods; after this the embryos were fixed and sectioned. The operative mortality was high, but eight specimens developed successfully and were fixed at periods of between five and nine days of incubation. Some regeneration of the ablated eye always took place, but the rudiment so formed never approached the size of the undamaged eye.

Essentially similar conditions were found in all eight specimens. The appearance of the interorbital septum (Fig. 1) was virtually normal and did not differ significantly from that of controls of the same age. It seems, therefore, that the fusion of orbital cartil-

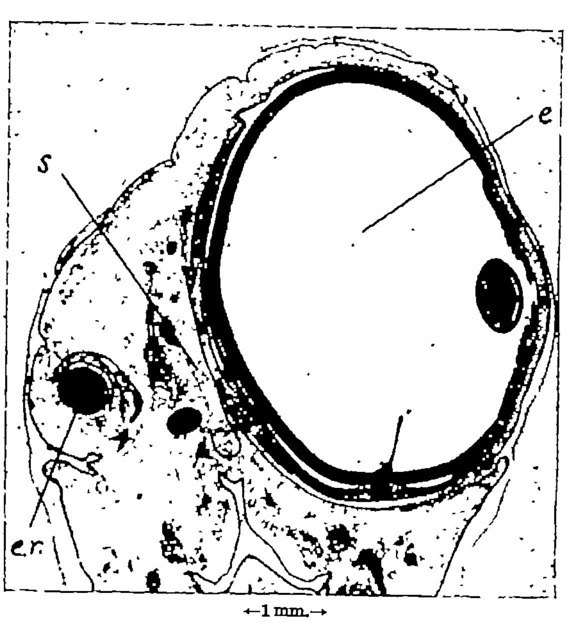

Fig. 1. Transverse section through head of operated 8½-day chick embryo (Masson's trichrome). *e*, normal eye; *e.r.*, regenerated eye rudiment; *s*, interorbital septum

ages, trabeculæ and intertrabecula and the regression of the lateral parts of the orbital cartilages are not affected by severe damage, resulting in drastic reduction of size, to one eye, performed about 48 hr. before the cartilages of the skull become foreshadowed as visible condensations of mesenchyme. The scleral cartilage, on the other hand, conformed to the size and shape of the regenerated eye rudiment, though parts of it were thicker than the cartilage on the undamaged side.

It is of interest that a naturally occurring anomalous chick embryo of seven days simulated the experimental specimens very closely; the left eye was rudimentary and malformed, with a thick but appropriately shaped scleral cartilage. The interorbital septum was essentially normal in appearance, and no abnormalities elsewhere in the head were detected. Comparable conditions have been observed in a microphthalmic embryo of the lizard, *Lacerta vivipara*, another tropitrabic form.

The results of these experiments seem to agree closely with those of Weiss and Amprino[2], and Amprino[3], who were, however, concerned with the effects of eye reduction on the sclera and other accessory orbital structures rather than on the skull proper.

## "Work Study"

The article on "Work Study" in *Nature* of July 23* may, I fear, raise quite unwarranted prejudice in the minds of readers. The term 'work study' is now commonly accepted in British industry as being very much wider in scope than the mere application of financial incentives based on time study.

Work study may be defined as "the systematic and objective examination of all the factors which directly govern the productive or operational efficiency of any specified activity in order to effect improvement". It is thus founded on scientific analysis and measurement in order to determine the facts of the situation and to eliminate guesswork and the dead hand which past custom can exert in the face of changing circumstances.

The first, indeed the most effective, of the techniques involved in work study is method study applied in a strictly logical and scientific manner. From this angle, it may truly be said that work study aims first at improving the efficiency of management, and thereafter, as a result, at obtaining more effective (not necessarily harder) work from all concerned.

In order to carry out method study effectively, and to determine the true facts of any activity which is under examination, it is indeed necessary to apply measurement to all the factors, including machine utilization and human activity. Such work measurement is a means of establishing a realistic basis for costs, for production planning and labour allocation. Experience shows that it is amply justified for these reasons alone by providing data on which efficiency can be improved and progress be measured.

Should it be desired to institute monetary incentives for the operatives in order to encourage the highest reasonable level of individual interest and effort, work measurement does indeed offer an appropriate basis. It must be stressed, however, that incentives of this or any other kind will only be effective if their application is made after full consultation and by arrangement with the trade unions and the operatives directly concerned. It is essential to ensure their understanding of what is proposed and the beneficial results to themselves, to the organization in question, and ultimately to the community as a whole, which should accrue.

If individual incentives are to be offered, it is desirable that these should be founded on careful work measurement with its insistence on finding the facts in an objective manner, rather than an outmoded system, such as the price-list, or even piece-rates, which tend to be based on rule-of-thumb and bargaining methods, with inevitable anomalies and the likelihood of disputes. It is true that work measurement and time studies, like any other technique, may be badly applied; but such cases are due to lack of training or objectivity on the part of those responsible, and not to any fundamental failure of the techniques themselves.

Lord Kelvin truly said, "When you can measure what you are speaking of, and express it in numbers, you know that on which you are discoursing. But when you cannot measure it and express it in numbers, your knowledge is of a very meagre and unsatisfactory kind".

It is surely high time that we attempted to apply the scientific method not only in the laboratory but also in the day-to-day conduct of affairs where it is so desperately needed but is all too often absent.

There is now overwhelming evidence of the benefits which can accrue from the wide application of work study principles, whether or not these include the final step of individual incentives based on measured work. It is clear, too, that where management exercises its function with proper human understanding coupled with a critical scientific approach based on fact-finding and thorough analysis, the psychological atmosphere as well as technical efficiency can be greatly improved.

The British Productivity Council is representative of the national employers' organizations and of the trade unions through the T.U.C. Among its other activities, it has set up a Work Study Unit to act as an interpreter of the best current practices in this field. This Unit is in great demand and is proving highly successful.

For the above reasons, I consider the note in *Nature* to be defeatist and not in accord with the facts. It is also wrong to suggest that work study is so limited in its aims and ineffective in its results.

Experience shows that work study does in fact provide one of the most valuable means of improving production efficiency. Not least, it stresses the community of interest between operative, management and customer alike, and encourages understanding, interest and pride on the part of all concerned in effecting continuous improvement so that all may benefit.

# FORTHCOMING EVENTS

## Monday, October 3

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. Cosler: "Electronics in Industry".

British Ornithologists' Union (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 6 p.m.—Annual Scientific Meeting.

Royal Institute of Chemistry, London Section (joint meeting with the London Section, Society of Chemical Industry, in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. R. Barrington Brook: "The Production of Scientific Apparatus".

## Tuesday, October 4

Institution of Chemical Engineers, and Society of Instrument Technology (in the Assembly Hall, Church House, Great Smith Street, London, S.W.1), at 9.45 a.m.—Joint conference on "Automatic Control in the Process Industries".

Bone and Tooth Society (at the Institute of Orthopaedics, 234 Great Portland Street, London, W.1), at 5 p.m.—Symposium on "Organic Components and Bone and Teeth". Dr. J. E. Eastoe: "Some Chemical Aspects of the Organic Components of Bone"; Dr. Maurice V. Stack: "The Chemical Nature of the Organic Matrix of Dentin and Enamel"; Dr. H. G. B. Slack: "The Turnover of Collagen and Mucopolysaccharide".

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. Dolman: "Radio Aids to Marine Navigation".

## Wednesday, October 5

Society for Analytical Chemistry (in the Meeting Room of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

## Thursday, October 6

Physical Society, Low Temperature Group (in the Lecture Theatre, Royal School of Mines, Prince Consort Road, London, S.W.7), at 3.30 p.m.—Résumé of Papers Read and Discussed at the Ninth Congress of the International Institute of Refrigeration and the International Union of Physics held in Paris. Speakers: Dr. Brewer, Dr. Cooke, Dr. Parkinson, Dr. Din and Dr. Powell.

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Sir George H. Nelson, Bart.: Inaugural Address as President.

## Friday, October 7

Society of Chemical Industry, Fine Chemicals Group (in the Chemistry Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Dr. W. Gerrard: "The Reactions of Alcohols with Halides".

## Friday, October 7—Sunday, October 9

Institute of Personnel Management (at The Royal Hall, Harrogate)—National Conference, 1955.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Advisory Officer (with a degree in agriculture or botany) in the Department of Agricultural Botany (Grassland Section)—Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (October 8).

Chemist (with degree in chemistry or equivalent qualification, with experience of investigational and research work and preferably with knowledge of modern instrumental techniques) at the National Coal Board Central Laboratory, Pendlebury, Manchester—Establishment Officer, National Coal Board, N.W. Division, 40 Portland Street, Manchester 1 (October 8).

Social Development Officer (with a degree or diploma in social science and with experience of community development work) with the Government of Tanganyika, to help initiate development plans and instruct local staff—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.178/8/08 (October 14).

Assistant (with a good qualification in chemistry with some knowledge of biology) in the Chief Engineers' Department, Chemistry and Metallurgy Sub-Branch, Bankside House, London, for administrative and theoretical work concerned with water treatment, effluents, timber degradation and in general with problems in which chemical engineering and chemistry are blended with biology—Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting AB/618 (October 15).

Demonstrator or Tutorial Student (preferably with an interest in organic chemistry, particularly that of natural products) in the Chemistry Department—Registrar, University College of North Staffordshire, Keele, Staffs. (October 15).

Lecturer (with training and experience in the bio-physical aspects of physiology) in Physiology—The Secretary, The University, Aberdeen (October 15).

Assistant Lecturer (with a science degree, with special qualifications and postgraduate experience in entomology or helminthology) in Zoology—Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (October 17).

Lecturer (with good honours degree and preferably with some teaching experience) in Economics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (October 17).

Lecturers (2) (with good honours degree and preferably with teaching experience) in Mathematics at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (October 17).

Mechanical Engineers (2) in the Department of Irrigation, Ceylon—High Commissioner for Ceylon in the U.K., 13 Hyde Park Gardens, London, W.2 (October 17).

Senior Lecturer and Lecturer in Pathology at the Royal Infirmary, Glasgow—The Secretary of University Court, Glasgow (October 17).

Engineer (with degree in civil engineering, membership of the Institution of Civil Engineers or equivalent professional qualification, with ability to formulate technical policies and procedures appropriate to civil engineering design, and to plan, direct and co-ordinate such work) in charge of Civil Engineering Design, Civil Engineering Division of the Snowy Mountains Hydro-Electric Authority, for duties including the final location and design of civil engineering works, including dams, pressure tunnels and shafts, power stations, mostly underground, aqueducts and associated hydraulic structures, mountain roads and buildings, preparation of specifications and co-ordination of design work being carried out by other agencies for the Authority—Chief Administrative Officer, Snowy Mountains Hydro-Electric Authority, P.O. Box 32, Cooma 48, N.S.W., Australia (October 19).

Senior Clinical Psychologist (with honours degree in psychology or equivalent qualification, preferably with psycho-analytic training and experience), for duties mainly in the Department of Child Psychiatry—Chief Psychiatrist, West Middlesex Hospital, Isleworth, Middlesex (October 24).

Lecturer in Soil Science in the Faculty of Agriculture, University of Sydney—Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 28).

Chair of Radiology (Diagnostic) at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (October 31).

Demonstrator in the Department of Chemistry—Registrar, King's College, Newcastle-upon-Tyne (October 31).

Demonstrator (honours graduate in metallurgy, physics or chemistry) in Metallurgy—Registrar, College of Technology, Manchester 1 (October 31).

Biologist (with an honours degree for which an adequate study of zoology or biology was necessary)—Secretary, Salmon Research Trust of Ireland, Inc., c/o St. James's Gate, Dublin (November 1).

Assistant (graduate in metallurgy, chemistry or physics, preferably with foreign language knowledge) in the Information Department, for abstracting, literature searching, editorial work, indexing and translating—Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

Assistant (with a British university degree, preferably in science, able to conduct correspondence and be methodical, dependable and sociable; a knowledge of foreign languages desirable) to the Director of the Ciba Foundation, London—Messrs. Swepstone, Walsh and Son, 3 Pump Court, Temple, London, E.C.4.

Assistant Conservator (with a university degree in forestry) of Forests, Sierra Leone—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.61/15/04.

Assistant Physicist (with good honours degree in physics and preferably with some experience of electronics), to assist in radioisotope and X-ray work, including rotational therapy—The Secretary, Newcastle Regional Hospital Board, Walker Gate Hospital, Newcastle upon Tyne.

Head of the Department of Chemistry and Biology—Registrar, The Technical College, Sunderland.

Lecturer (with teaching experience, and preferably with industrial experience) in Physical Chemistry at the West Ham College of Technology—Chief Education Officer, Education Offices, 95 The Grove, London, E.15.

Lecturer (with high qualifications in the general field of applied chemistry and chemical engineering, and preferably with some experience of teaching, research and industry) in Technical Chemistry—Secretary-Treasurer, Royal Technical College, Glasgow.

Physical Metallurgist (with a university degree or equivalent qualification, preferably with some postgraduate research or industrial experience), for work in a research group concerned with measurements of fundamental properties of iron and steel—Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting M.G.1.

Principal or Senior Scientific Officer (with first- or second-class honours degree in chemistry, with experience in chemical engineering and applied chemistry problems or in chemical engineering with additional research and development experience, or equivalent qualifications), to lead a team concerned with chemical process development and plant design studies—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks., quoting A.573/34.

Research Student (with a good honours degree in physics or metallurgy) in the Department of Physics, for research work on the physical properties of liquid metals—Professor of Physics, The University, Southampton.

Scientific Officer (with first- or second-class honours degree in chemistry, preferably with some research experience of physical chemistry and knowledge of high vacuum techniques as applied to gases and metals, distillation practice and theory, and radio chemistry) for basic research in inorganic and metallurgical chemistry—Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting A.511/34.

PRECISION BS INSTRUMENTS

**Refractometers for Industry and Research**

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

*Full particulars sent on application.*

*We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.*

# EDUCATION AND THE UNIVERSITIES

LOOKING back over the programme of the meeting at Bristol of the British Association, the prominence of educational issues is noteworthy. They were specifically mentioned by Sir Robert Robinson in his presidential address, they were implicit in Prof. H. D. F. Kitto's evening discourse, and also in the presidential addresses of Mr. W. B. Mercer to Section M (Agriculture) and of Mr. Ritchie Calder to the Assembly of Corresponding Societies, and there were discussions on the training of the physicist and the teaching of chemical principles in school and university in which the appropriate section joined forces with Section L (Education). Of the discussions in the Education Section itself, that on "Man and his Machines", like the presidential address of Mr. J. F. Wolfenden and also Dr. J. Bronowski's address "The Educated Man in 1984" at the final session on September 7, were related also to this theme.

Broadly speaking, two main groups of issues were raised. The first relates to the training of the scientist himself, and the supply of trained scientists and technicians in sufficient numbers to meet the changing needs of society. The second relates to the interpretation of science and involves the general education of the scientist and the education of the community as a whole, so that it is competent to appreciate the scientific aspects of a problem when they are reasonably interpreted in non-technical language. The two sets of issues are interrelated, as was well shown in both Mr. Wolfenden's address and by Dr. Bronowski, as well as in the discussion on "Man and his Machines". Sir Ben Lockspeiser was emphatic that many more scientists and technologists are required than are available, as well as many more teachers of mathematics and science in the schools to supply them, and strongly disagreed with Dr. J. E. Richardson's view that no large increase in the number of technicians will be required by automation.

Although, however, we may succeed in attracting into careers in science and technology a sufficient number of those at present leaving school too early in order to enter on other careers, without detriment to the nation's proper requirements elsewhere, it would still appear that the balance between technologist or scientist and technician requires further investigation. It is likely to vary widely in different industries. Dr. J. E. Richardson's estimate could be reasonably correct for the electrical industry but wide of the mark elsewhere. Without, however, some rough idea of the quantitative demand, it is impossible to plan the expansion of technical or of technological education soundly.

At Bristol the qualitative issues, in the main, were discussed. It is true that if the quality of technical education and technological education in Britain is high, problems of adjustment to changes in demand for one category or another will be less acute, and all the more so if due attention is given to human aspects and to those liberal studies which were emphasized by Mr. H. A. Rée and in the recent report "Liberal Education in a Technical Age". None the less, the quantitative aspect requires greater attention than it has yet received, even in respect of university education. To read again in the light of to-day such an address as Mr. H. T. (now Sir Henry) Tizard gave to the Education Section of the British Association twenty years ago—with its reasoned argument that the universities were then too full, that we should concentrate not on increasing the number of university-trained scientists but on raising the standard, and aim at producing chiefly the leaders of the profession—is to be brought face to face with the questions: What is the real purpose of a university education in science, in technology or in any other faculty? And what are the real functions of the university in relation to the training of educated men and women or of the formation of informed opinion in society as a whole? How best and in what ways should a university serve society in the present times?

Sir Henry urged that it should be the function of a university school of engineering to send out from the university resourceful men whose education and outlook would enable them to attack with confidence the new problems perpetually arising in their chosen field. He urged also that science well taught could supply all that is best in the classical tradition, imparting accuracy and exactness and a discipline in clear thinking; that it could brace with its difficulties minds that are not afraid of obstacles and inspire with its beauty minds not insensitive to beauty. To-day, we find Sir Charles Morris, in his Joseph Payne Memorial Lectures at the College of Preceptors on the idea of university education, emphasizing that the primary educational duty of the university is to develop the power and habit of disciplined thinking and encourage the capacity to form good judgments. The most fundamental aim in education, he urges, is the development of the power of good judgment in answering the questions which cannot be answered by science but which must be answered in life—problems which no intensification of scientific training by itself will solve. Unless, however, the student acquires in his undergraduate years not only scientific understanding and skill in scientific method but also learns to practise and develop the powers of non-scientific judgment and decision, the university has failed in its task of producing an educated man or woman. On the other hand, in the measure in which it has developed that capacity and habit, it has largely solved the problem of education for citizenship.

Dr. Eric James put the issue in very much the same terms in his Science and Citizenship Lecture to the Science Masters' Association at King's College, Newcastle upon Tyne, when he argued that the education that produces scientists must be broadened and strengthened in such a way—at any rate for the best of them—as to supply the opportunity that the best arts courses provide of discussing the general questions of social organization and human conduct. If the problems of our present civilization are to be solved, we must produce men of science not only in greater numbers and of great technical skill, but also able and determined to take their place as responsible citizens. They must, he continued, understand the dangers and the opportunities that are provided by the discoveries they themselves are making, and be prepared and equipped to lead mankind to resist the temptations of purely material triumphs and to use science, not as a means of enslavement, but as a force for the liberation and enrichment of the human spirit.

The essence of Dr. Bronowski's lecture to the Education Section at the Bristol meeting of the British Association was that this, though good in itself, is not enough. We would still in the next generation create a slave world unless we make certain that science is a part of the cultural education of all, and that the language of science is understood by the ordinary citizen. It is in this sense that we have to make science a part of our culture, and to ensure that the ordinary citizen has the capacity to see through any kind of nonsense, scientific as well as political, economic or social, and recognize a duty to resist and expose such nonsense.

In large measure that capacity is a condition of the effective functioning of a democracy, as was indeed recognized by de Tocqueville more than a century ago; nor can it be contended that we have gone far towards achieving that objective. Pragmatic educational objectives have indeed been concerned much more with the acquirement of professional or technical skills than with the stability of the whole system, upon which in the end the economic and social and political order really depend. When the Duke of Edinburgh, in his opening address to the Conference of Vice-Chancellors and Rectors of more than a hundred European universities at Cambridge last July, spoke of the great responsibilities of the universities of Western Europe to-day, he emphasized that this task of turning out pupils capable of recognizing and resisting unsound views belongs primarily to the universities rather than to the general educational system.

That in some degree is inevitable, but it can only safely be conceded if the universities interpret their detachment and independence as involving some responsibility for independent criticism and outspoken comment on issues of the day when the people are being misled in matters of fact. For such guidance to be given effectively, there must be some considerable measure of public understanding of the work and purpose of a university, and thus it comes about that the universities can only fulfil their responsibilities to-day if that public understanding exists, just as in Britain their increasing dependence on public funds makes public understanding the final safeguard of their freedom. The very extent to which the British Association meeting focused attentio upon the education of the scientist and the educatio of the public in science suggests that the Associatio and its members are aware of the needs of to-day for the recent meeting has at least clarified some the issues which must be widely understood if th necessary changes in policy are to be made within without the universities.

The discussions at the British Association meetin received the wider publicity; those at the universitie conference, as would be expected, attracted muc less attention but went deeper. Moreover, the Conference in itself directed attention to a furthe function of the universities which Prof. A. Haddo mentions in his contribution to "The Bomb: Challenge and Answer". Scientists, says Prof. Haddow are troubled by doubts as to whether the universitie are using their resources most constructively i discharging their responsibilities not so much to thei countries as to the world. This is, of course, i contradiction to the view expressed by the Inter University Council for Higher Education Overseas which in reviewing recently developments betwee 1946 and 1954 commented that these development had appeared in a period in which the prestige o universities has never been higher, and in which the have been exceptionally responsive to their nationa and international responsibilities.

It was perhaps fitting that Prof. Haddow shoul give expression to any legitimate doubts on thi matter in that particular connexion, for no society o institution can bring men closer together than university; and the contribution which universitie could make in promoting international understanding, while it should not be overstressed, is indispensable It should not be forgotten, however, that though response to the suggestion which Mr. Robert Birley made six years ago in his Reith Lectures has been disappointing, and perhaps the universities migh have made more determined and constructive efforts to fashion a common culture in Europe, the hindrances to the interchange and migration of scholars and students are not of their making. If progress in the task of restoring some of the old international relations between universities and giving them a new significance, broader and more humane, than before, so that each nation is assisted to make its own special contribution to the common stock and absorbs much in return without losing its individual characteristics, the fault has lain rather with governments. The Conference at Cambridge demonstrated that universities are alive to the great importance of encouraging university study abroad in promoting the free exchange of ideas, and Sir Edward Appleton asserted that a university's function is pre-eminently to discover, or perhaps uncover, the spiritual and intellectual needs of society.

The Cambridge Conference at least encourages the hope that the universities will draw closer together not only in support of the free communication of knowledge by interchange of staff and students and by discussion and publication, but also in serving this function. In doing so, however, the universities must be no less careful to maintain their own academic standards of sound learning and scholarship than has been the Inter-University Council for Overseas Education in watching over the development of the Colonial universities and university colleges. Extramural activities must not be pursued in a way or on a scale that leads to the lowering of standards; and this needs to be remembered in considering the universities' contribution to adult education at any level, and in assessing the demands on the universities for particular courses and perhaps especially courses in general education.

Here again Sir Henry Tizard said some wise words in the address already mentioned, and they are as pertinent to-day as when they were uttered. If university authorities complain that students are lacking in general education, it is for them, he urged, to do their best, by altering the conditions of entry or the standard of scholarships, to help schoolmasters to remedy the defects. "If it is really the general view that the school education of a student of science is too narrow, then the best practical step is to reform the University Matriculation examination, and make it appropriate to the normal age of entry. . . . If it is not considered worth while, the criticism of the general education of the science student loses most of its point."

These observations are worth recalling in considering the report on university entrance requirements which has recently come from a sub-committee of the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom, if only as a reminder of the wide background in which such decisions should be taken. They do not affect simply the training to be given to the university student, or the maintenance of university standards. They affect equally the character of secondary education as a whole, even the outlook and attitudes which determine whether or not a student turns towards a career in science or technology. Indirectly, they bear closely on the promotion of public understanding of the work of the universities as well as of the scientist and, if not the way in which the universities must carry out their educational work, very largely the character and extent of that work as a whole. If indeed we ceased to allow sectional views to influence decisions which should be taken primarily in regard to the educational needs and policy of the country as a whole, it might well be found that an appropriate solution of the problems of university selection and of university entrance requirements might so react on the work of the schools and of adult education generally that the demands on the universities for extra-mural work were considerably eased and much more readily confined to those of appropriate academic character. It can at least be said that, without imagination and insight, without more readiness to experiment than has frequently characterized the relations between school and university during the past twenty years, it will be difficult indeed for the universities either to fulfil their full responsibilities to the community, or to ensure the public understanding and support which will safeguard the freedom and trust in which their work is most fruitfully done.

# LITERATURE OF THE SCIENCE OF THE PAST

## Scientific Books, Libraries and Collectors

A Study of Bibliography and the Book Trade in Relation to Science. By John L. Thornton and R. I. J. Tully. Pp. x+288+12 plates. (London: Library Association, 1954.) 24*s*.

It is an ambitious task that the authors of this book have undertaken, to give within 270 pages a well-documented citation of all the chief books in all branches of science from before the days of printing up to the end of the nineteenth century, supplemented by brief accounts of relevant bibliographic matters, such as the growth of scientific periodical literature (illustrated, incidentally, by a reproduction of the title-page of the first volume of *Nature*) and scientific publishing and bookselling. It is pleasant to be able to say that, considering the manifold difficulties, they have succeeded admirably. Where the more important authors are in question, a very short indication of what they accomplished is given, as well as the title, date and place of publication of their chief works; and even the lesser ones are given a few biographical lines. For those who want fuller information, the footnotes and the bibliography at the end give ample guidance as to whither to turn. This bibliography cites some 450 names, many with more than one publication to their credit, and this alone bespeaks long and expert work.

The first chapter, "Scientific Literature before the Invention of Printing", deals with authors, such as the Greeks and Alexandrians, writing in that period, but is chiefly concerned with printed editions of their works. Among the many odd facts that can be gathered in the next chapter, on "Scientific Incunabula", is that, whereas Italy has, according to one list, 1,445 such books to her credit and Germany not many less, England claims 23 only: the figures for incunabula of all kinds in the British Museum give England about a tenth the number set down to Italy. Apparently science was relatively unpopular with our early printers.

The seventeenth century, although not easy, was, perhaps, the simplest task. A grave omission is Guericke, and certain other German writers, such as Schott, might have been mentioned. Papin is another outstanding figure who is absent, as is Savery. The eighteenth century, with increasing publication, obviously demands careful selection: on the whole, the choice is very well made, but static electricity fares rather badly, both in authors and in the fact that one of the chief bibliographies is not cited. McKie's important work on the chemistry of the century is duly acknowledged. With the nineteenth century, the growth of scientific literature becomes, as the authors say, overwhelming. Much is done by citing bibliographies and other works, such as, in chemistry, those of Partington, to help the student without overloading the book. Anyone versed in the subject will note the absence of well-known names, especially in mathematics—Cantor's "Geschichte der Mathematik" is not mentioned—but clearly there is not room for everybody, even every distinguished body. When it is considered that all sciences, including, for example, conchology, are represented, it must be readily admitted that the authors have done well. The final chapter on "Scientific Libraries of To-day" is a valuable guide to the libraries of Great Britain.

This learned and laborious work will be of great use both to librarians and to students of the history of science. When a new edition is called for, no doubt certain omissions, including those to which passing reference has been made and others that have been noted, will be remedied. A citation of English translations, where they exist, of works in foreign tongues might be well. A desirable addition would be a list of the Latin names given to cities in Latin editions of the seventeenth and eighteenth centuries. There are frequent references in this book to editions at "Geneva and also Coloniae Allobrogorum", but Geneva and Colonia Allobrogorum are the same place. It is pleasant to be able to end this notice not with the reviewer's customary complaint of an inadequate index, but with grateful acknowledgment of a full and excellent one, which adds to the value of the book.

E. N. da C. Andrade

# A REFERENCE WORK OF HYDRAULIC ENGINEERING

## Irrigation and Hydraulic Design

By Dr. Serge Leliavsky. Vol. 1: General Principles of Hydraulic Design. Pp. xiii+492+13 plates. (London: Chapman and Hall, Ltd., 1955.) 126s. net.

THIS book is the first of three volumes dealing with the problems of irrigation engineering, and sets out the basic principles of design founded on the author's considerable experience of irrigation and hydroelectric systems of the Dnieper and Nile. The book is intended as a work of reference, and its length and the historical treatment adhered to throughout certainly preclude its use as a handbook.

The book is divided into three chapters. The first treats problems of flow through a pervious soil, as they affect the design of hydraulic structures. Starting from the basic concepts of flow in a homogeneous, porous medium, the author passes to discussions of uplift pressures, potential flow and the analytical methods of computing flow nets and base pressures for various foundation arrangements. This section, which is treated most exhaustively, is followed by a treatment of graphical and experimental methods for determining the flow net, approximate calculation by the method of independent variables, percolation in non-homogeneous soils, piping and finally percolation through earth embankments. In view of the limitation of the analytical methods to foundations, in which the geometry is fairly simple, more space might with advantage have been devoted to the more general, if less precise, methods.

The arrangement of the discussion of the theories of piping and uplift pressure is rather confusing. The Bligh creep-head theory is presented together with the earlier Terzaghi liquefaction theory, while Lane's weighted creep theory is reserved for a later section. Although he states that Lane's theory is but an extension of the earlier Bligh theory, the author fails to warn the reader of the dangers of their application to design. Modern practice in soil mechanics only admits the application of empirical design procedures when a more rational scientific approach is not available. Methods based on average soil coefficients must always be treated with suspicion. Also, the general problem of stability of weirs and failure due to shearing of the subsoil under conditions of upward seepage has unfortunately not been touched; neither has the potential instability at the toe due to vibration of the apron.

The second chapter deals with design methods for preventing or reducing scour downstream of hydraulic works. Early designs relied largely on a protecting apron downstream, and formulæ for the extent of the apron and the depth of scour to be expected were produced by Bligh and Khosla from an examination of existing weirs in India. The author shows that data for the depth of scour downstream of several barrages on the Nile confirm Khosla's findings, despite the approximate nature of the coefficients used. Later designs have been based almost exclusively on tests made with small-scale models, and a discussion of the underlying principles and the results occupies a large part of the chapter. As far as the motion of the water is concerned, the guiding principle of such tests is the conservation of the Froude number; but the parameter which controls the movement of bed material, and so is of paramount importance when relating scour in model and full scale, has not yet been settled. The author mentions the conflicting views of various authorities on the subject, without coming to any definite conclusion.

Apart from this question, models have been useful in revealing the flow patterns likely to occur in specific designs and have contributed largely to an understanding of the methods by which the standing wave can be used to reduce scour. One of the latest developments of this work referred to in the chapter is the production of a set of rules for the design of stilling basins to dissipate energy behind the wave in as short a distance as possible.

The last chapter consists of two sections. The first deals with uniform flow and traces the historical development of the subject from the early ideas of Galileo to the modern advances of Prandtl and his collaborators. The latter have succeeded in placing the subject on a rational basis, and the forms of the friction formulæ so deduced are rapidly supplanting the earlier purely empirical formulæ of Bazin, Ganguillet-Kutter and Manning. The second section is taken up with steady non-uniform flow and gives in considerable detail the various methods which have been used for integrating the basic flow equations, together with complete numerical tables and charts for their application.

The book is well illustrated and lucidly written and includes a good supply of references.

# ASPECTS OF THE ANIMAL CELL

## International Review of Cytology

Vol. 3. Edited by G. H. Bourne and J. F. Danielli. Pp. x+530. (London: Academic Books, Ltd.; New York: Academic Press, Inc., 1954.) 9.50 dollars; 76s.

THE thirteen articles which make up the third "International Review of Cytology" have in common a concern with some aspect or other of contemporary cell biology, the technical quality of their production, and the price one must pay to possess one or more of them. The first needs no comment, the second is good, and the third, by present-day standards, is not excessive. For the rest, each article should, but in a short space cannot, be treated separately on its merits. It would not be right, even were the reproach just, to complain of a lack of balance in the choice of articles in what is only one volume of a continuing series. In fact, however, the editors have ranged widely over the field of animal cytology, and one's only fear is that the plant cell, which had a foothold in the first two volumes, has been deliberately excluded and not simply temporarily overlooked.

In no other field of biology does the worker lean so heavily upon his techniques or have to use such care in assessing their reliability. Hence most of these articles are to some extent critical surveys of the technical procedures relevant to their problems, and three of them (Chr. de Duve and J. Berthet, on differential centrifugation in the study of tissue enzymes; A. G. Everson Pearse, on azo dye methods in enzyme histochemistry; Roy G. Williams, on transparent chamber methods for work on living mammals) have the results of particular techniques as their main theme. Three others take a particular tissue element (G. Asboe-Hansen, the mast cell; E. W. Dempsey and A. I. Lansing, the elastic tissue; S.-O. Brattgard and H. Hyden, the nerve cell) and survey the knowledge of its composition, structure and function revealed by classical and by recent methods of research.

The behaviour of living cells or of cell populations is treated by Charity Waymouth in a review of the nutritional requirements of cells in culture, by T. Gustafson in a survey of enzymatic aspects of embryonic differentiation, and by I. Cornman in a brief discussion of the action of urethane on mitotic division. The nucleus alone is the hero of the remaining four articles. O. Bucher reports the measurements, made in his laboratory, of nuclear and nucleolar size of cells in tissue culture, M. Alfert discusses the structure and composition of giant chromosomes, and R. A. Beatty variations in chromosome numbers in mammalian somatic cells. Finally, A. L. Dounce presents a critical survey of recent studies of the enzyme content of cell nuclei isolated by chemical means.

The reviewer of Vol. 1 pleaded for titles of papers to be given in the lists of references. If a reminder will strengthen the editors' hands in forcing this reform upon unwilling authors, it is gladly given.

D. R. Newth

# ADMINISTRATIVE CLASS OF THE CIVIL SERVICE

## Higher Civil Servants in Britain from 1870 to the Present Day

By R. K. Kelsall. (International Library of Sociology and Social Reconstruction.) Pp. xvi+233. (London: Routledge and Kegan Paul, Ltd., 1955.) 25s. net.

The scope and nature of this book are better indicated by the title of the article in the October–December, 1954, number of the *Political Quarterly*, in which Mr. R. K. Kelsall discussed the data obtained in a study of the social origins of members of the administrative class of the Civil Service above the rank of assistant secretary in three selected years at roughly ten-year intervals—1929, 1939 and 1950. It is concerned solely with the social origins of these senior Civil servants and, as a secondary issue, with promotion within the Service. It is not accordingly a book about the Higher Civil Service in the sense of Mr. H. E. Dale's earlier book. It is much more limited but contains an immense amount of data on the social background of the senior Civil servant from 1870 to the present day, covering the several routes of entry, the pattern of representation of schools and universities and the occupation of the fathers of the groups examined. There are also a brief review of the position of women in the Administrative Class and a comparison of the social characteristics of the heads of six departments in 1888, 1912, 1929 and 1950.

Mr. Kelsall's treatment of the data he has collected so carefully does not, however, match the assiduity with which it was assembled. His discussion is subjective rather than objective, and appears to be dominated, first, by the assumption that access to a post in the Administrative Class of the Service is a natural right of every citizen, and, second, that promotion from the ranks is intrinsically superior to examination entry as a method of recruitment. These assumptions are nowhere discussed, nor are their implications considered; but they colour Mr. Kelsall's discussion of the nature of the profession and thus rob it of any claims to be a serious contribution to the discussion of the adequacy of the Higher Civil Service to-day and what measures of reform are required.

These preconceived ideas prevent Mr. Kelsall from pausing to consider either the nature and limitation of the duties of the Administrative Class and the relation of such Civil servants to their Minister, or whether social background and traditions of certain groups may not give them certain inherent qualifications as public servants which are as much to the public advantage as to their own. That the Civil Service should be widely representative of the different sections of the community is all to the good. It is egalitarianism run mad, however, to suggest that the different sections should all be proportionally represented and to ignore the fact that a tradition of public service and political sense, at least as much as the resources to acquire a university education, have been responsible for generation after generation of certain classes or professions sending their sons into the Civil Service or Armed Services, just as it still supplies the great bulk of voluntary service.

In his essay in the *Political Quarterly*, Mr. Kelsall showed himself aware that recruits from certain classes might have their own faults and suffer from inherent disadvantages, but his obsession with egalitarianism and his conception of the ideal Civil servant as an imaginative, intelligent, forceful reformer, preferably trained in the social sciences, leads him to overlook the fact that if a Civil Service of high character and appropriate to the needs of to-day is to be recruited widely, the corollary to opportunity is a gradual raising of educational and cultural standards generally throughout the community which will even out not so much differences in wealth as in cultural outlook and standards. When the working class begins to provide voluntary workers in the way that the middle class has done for generations, we may expect it also to provide recruits for the Civil Service of the same calibre as the middle class has long been doing. The problem is not so much one of educational opportunity as of general education; nor has Mr. Kelsall really faced the difficulties inherent in the expanded promotion policy he advocates, and particularly the recruitment of the scientist to the Administrative Class.

R. Brightman

# THE GLASGOW 340-MeV. SYNCHROTRON

By DR. W. McFARLANE, S. E. BARDEN and DR. D. L. OLDROYD
Department of Natural Philosophy, University of Glasgow

THE electron synchrotron housed in the recent extension of the Natural Philosophy Department of the University of Glasgow was first operated at its maximum energy of 340 MeV. in April 1954. By the end of that year the gamma-ray output had been built up to a very satisfactory level, and the machine is now being employed for experiments on the photo-disintegration of nuclei and meson physics. A general view of the machine is shown in Fig. 1.

The magnet, a side view of which is shown in Fig. 2, was designed and constructed by Metropolitan-Vickers Electrical Co., Ltd., Manchester. It consists of a circular arrangement of twenty C-shaped units providing an annular gap of mean radius 125 cm., radial width 18 cm. and mean height 10·16 cm., within which the vertical guide field is established. Each unit is constructed from five parts: one vertical and two horizontal blocks of laminations, and two pole-shoes with a profile calculated to give the required field gradient. Two of the units have extended horizontal members in order to provide an air-gap for the passage of the gamma-ray beam. The magnet top, comprising the twenty upper horizontal members of the C-units, their attached pole-shoes and one of the exciting coils can, by means of a mobile crane, be raised in one piece weighing about 40 tons in order to provide access to the vacuum chamber. Induction acceleration is provided by twenty saturable flux bars placed within the electron orbit and clamped by means of wedges to the inner faces of the C-units.

The betatron flux and guide field are produced by the oscillatory current arising from the discharge of a condenser bank (860 μF.) through the twenty-turn coil situated within the C-units. One complete oscillatory cycle takes place during each pulse, the frequency of pulsing being adjustable up to five times per second. The original condenser bank failed to withstand the above operating cycle at the maximum potential of 17 kV., and almost a year was lost in the development of the project while new condensers of higher tolerance were manufactured. The switching is performed by an ignitron switch built by British Thomson-Houston Co., Ltd. This employs eight *BK* 56 ignitrons, four in parallel carrying each half-cycle of current. The ignitrons which conduct the first half-cycle are triggered by a pulse synchronized to a sub-multiple of the 50 c./s. mains, while those which conduct the second half-cycle are triggered by pulses from a biased peaking transformer in such a way

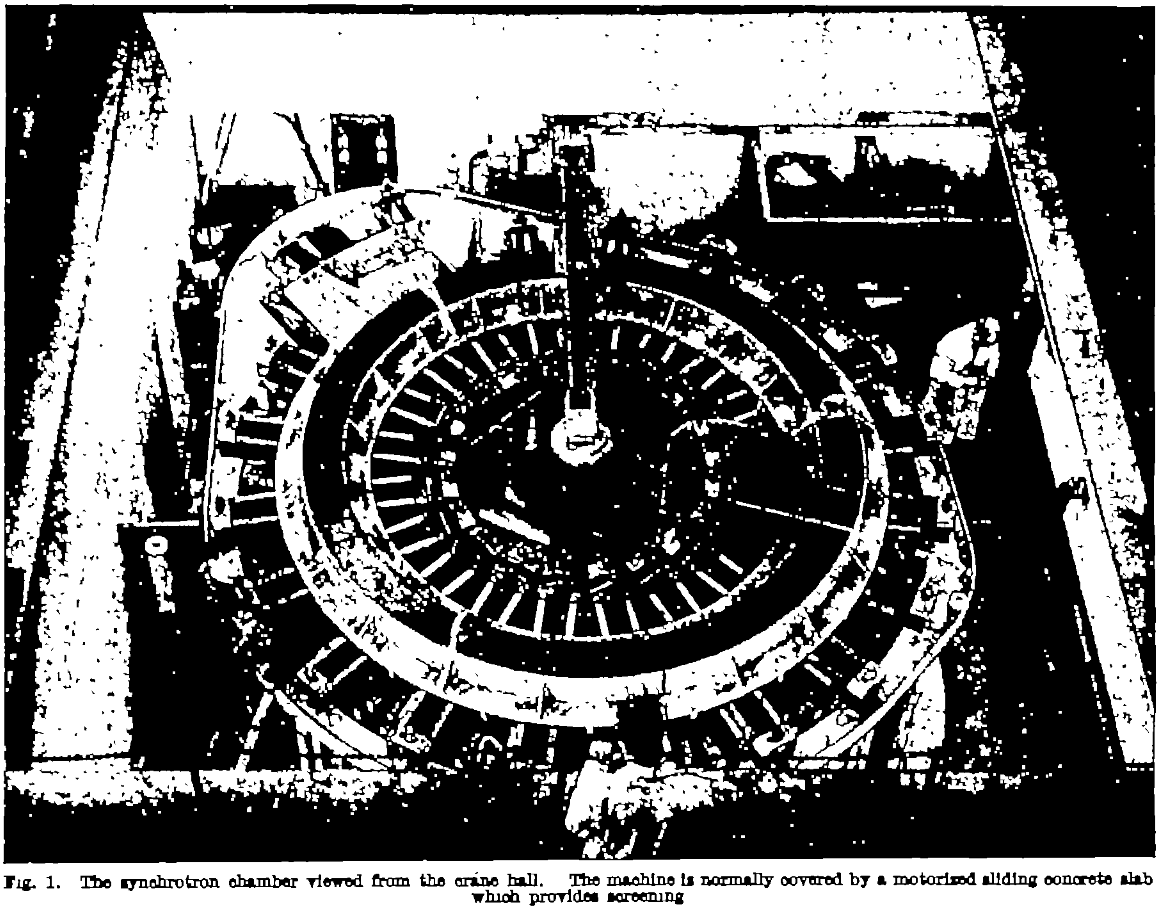

Fig. 1. The synchrotron chamber viewed from the crane hall. The machine is normally covered by a motorized sliding concrete slab which provides screening

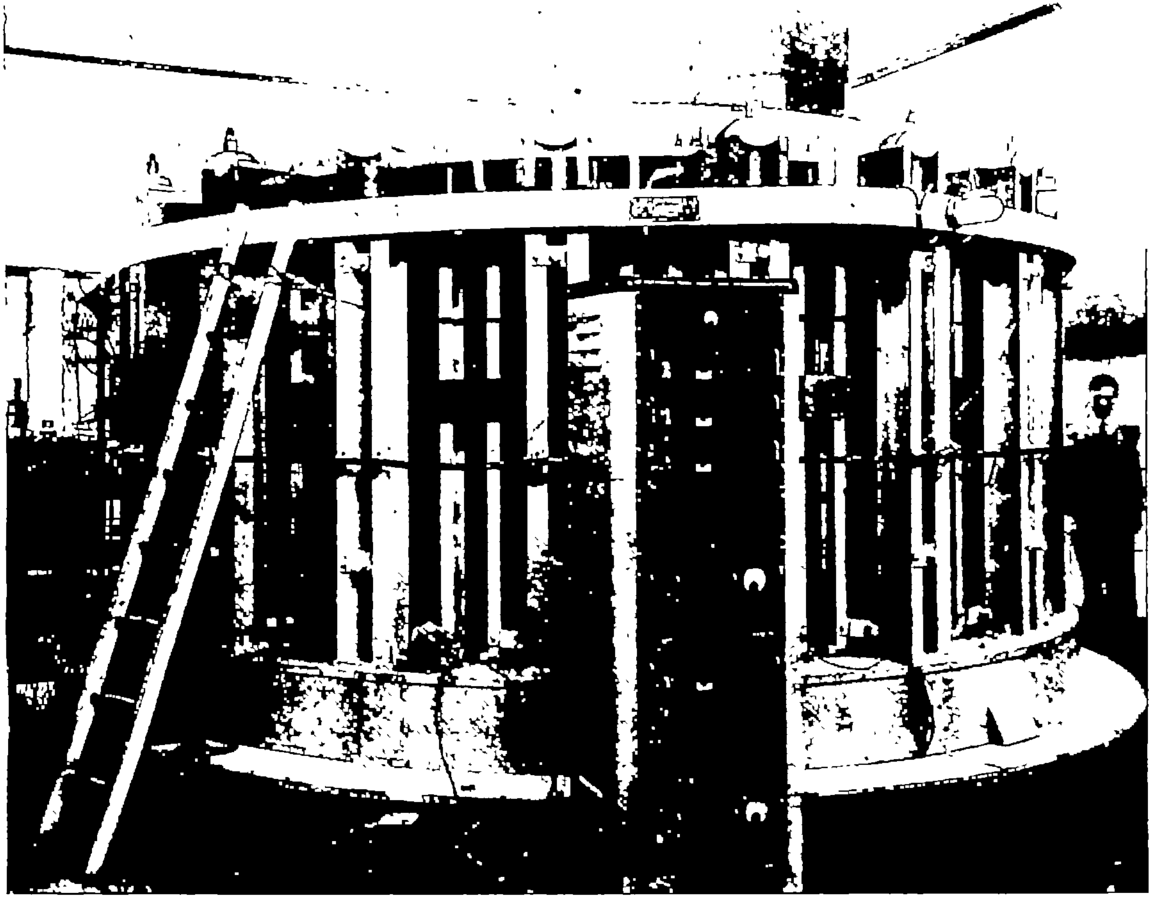

Fig. 2. Side view of magnet

that the magnet current passes smoothly through zero between the two half-cycles. At present the third quarter-cycle is the period during which electrons are accelerated. The average reactive power stored is 33 MV.amp., and the mean power-loss during pulsed operation is about 60 kW. The only cooling employed in the magnet is by forced air-draught upwards through the centre.

The charging current for the condensers is provided by a conventional three-phase hard-valve rectifier and passes through a series pentode valve (*E* 1807) which is used as a voltage stabilizer ; the maximum voltage permissible is 17 kV. Operation at 16·4 kV. provides a peak magnet current of 3,750 amp., which gives the guide field of 9,000 gauss necessary for electrons of energy 340 MeV. to move in a circle of radius 125 cm. The magnet inductance is about 40 mH. during betatron acceleration, but decreases to about 15 mH. when the flux bars are saturated. Thus $dB/dt = 0{\cdot}8$ gauss/μsec. at field zero, but increases to a maximum of about 2 gauss/μsec. The energy gain per revolution during the betatron phase is initially about 850 eV., adjustable to ± 1 per cent by remote control of flux-bar reluctance. When the bars are saturated, the energy gain per revolution is about 1,700 eV., which determines the minimum for the energy supply from the resonators.

Guide-field focusing is provided by the radial field gradient $\frac{dB}{dr} = n\frac{B}{r}$, where $0 < n < 1$ over the annular region $r = 125 \pm 6{\cdot}5$ cm. in the median plane. Three main sets of correction coils are employed. Control of the average value of $n$ around the complete orbit is provided by five concentric coils spaced 1 in. apart and attached to each pole face. The current through each of the ten coils is independently controlled so that median plane adjustments are also possible. Azimuthal variations of the radial gradient or the median plane can be removed, or introduced, by pole-face coils covering each of four quadrants situated at six radial positions 1 in. apart, alternating with the above set of circular coils. Azimuthal variations of remanent field or of rate of change of field associated with individual C-units are counteracted by resistance control of the currents induced in eight-turn coils around the vertical members of each unit.

The toroidal vacuum chamber (Figs. 3 and 4) is built up from moulded ceramic sections. There are nine plain sectors and eight with ports to provide access to the chamber, made of 'Frequentite'. The inner surface is coated with a thin continuous layer of platinum which has a resistance of 5–20 ohms per square. (The two resonators which complete the chamber will be described below.) The cross-section is roughly elliptical, with internal radial and axial dimensions 18 cm. and 6 cm., respectively, the wall thickness being about 1 cm. Adjacent sectors are spaced by 'Teflon' gaskets, the vacuum seal between them being provided by surrounding neoprene bands. Manufacturing tolerances reduce the clearance between the chamber and the pole-faces to about 0·5 cm. in places, leaving just sufficient space for the pole-face coils. The pumping system consists of a

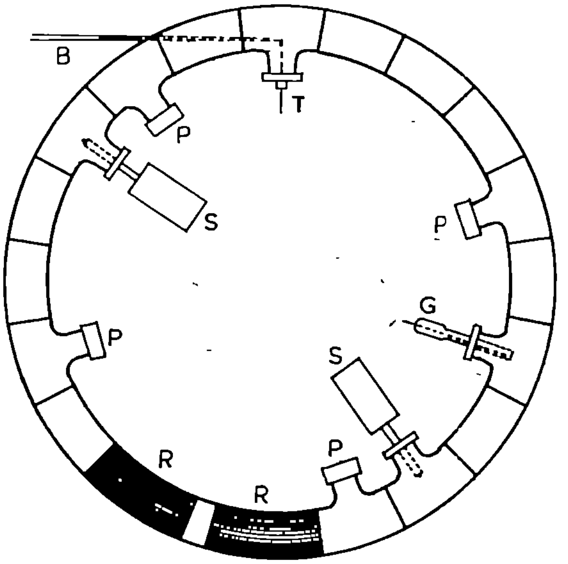

Fig. 3. Lay-out of vacuum chamber: *P*, pumping ports; *G*, electron gun; *S*, scintillator probes; *R*, resonator; *T*, target; and *B*, gamma-ray beam

Kinney rotary pump which provides the backing pressure for four 4-in. oil-diffusion pumps. The pressure in the vacuum chamber is usually about $2 \times 10^{-6}$ mm. of mercury.

Electrons are injected from a diode gun inserted through a port on the inner edge of the vacuum chamber. The anode is earthed, and the directly heated cathode is supplied with a negative trapezoidal pulse of duration about 5 μsec. and of amplitude about 70 kV. Up to 1 amp. of electronic current can be injected. Three motorized, remotely controlled adjustments permit the optimum disposition of the gun and its electrodes to be found during machine operation, these adjustments being radial movement, rotation and movement of the cathode relative to the anode. During the periods of rise and fall of the anode potential, a considerable number of low-energy electrons strike the inner wall of the sector housing the gun, ultimately causing sufficient damage to the metallized coating to produce erratic behaviour of the output. Repairs to this section are necessary at intervals of a few months. The timing of the injector pulse must be accurate to within 0·1 μsec. in order to maintain a steady output. This is achieved by feeding a pulse produced by a peaking strip mounted within the magnet gap into a multiar circuit which permits adjustment of timing within a selected limited range. The period during which electrons are accepted is about 0·4 μsec.

Synchronous electron acceleration is obtained by using two quarter-wave coaxial resonators. The conductor consists of a silver coating of at least 0·001 in. thickness, which is divided into strips about 1 cm. wide by longitudinal scribe lines in order to reduce eddy-currents. The lines on the inside are covered with a high-resistance film of 'Aqua-dag' to prevent charge accumulation. The resonators are fed, matched and tuned with the aid of two π-shaped slots in the outer silver coating. The gap across which the accelerating voltage is developed is located near one end. The two resonators with a small make-up sector between them occupy the same azimuthal angle as three normal sectors. They are placed with the accelerating gaps close together so that they must be fed approximately in anti-phase. Phasing is achieved by adjustment of the difference between the lengths of the two feed cables. The resonators are placed in a part of the vacuum chamber far removed from the point of electron injection in order to avoid the large direct beam from the gun which might cause accumulation of charge on the insulating gaps. The frequency range necessary is 38·2 ± 1·6 Mc./s., and the minimum total peak-gap potential is 1,700 V. The radio-frequency power source consists of a small master oscillator followed by two stages of frequency-doubling and power amplification, and a final push-pull output stage operated under class *C* conditions. The modulator pulse which is applied to the grid of the first doubler circuit is supplied from shaping circuits which provide control over the rate at which the radio-frequency voltage rises, its duration and the rate at which it falls. Timing is adjusted by means of delay circuits triggered from the instant of zero magnetic flux. It is found that betatron-synchrotron transition usually commences when the electron energy is about 4 MeV. with a radio-frequency of 38·3 Mc./s., the betatron orbit radius at injection being about 126 cm. The γ-ray beam is normally obtained by switching off the radio-frequency supply near peak field and allowing the circulating electrons to spiral inwards and strike a tungsten target. Sudden cut-off provides a beam of about 30-μsec. duration, but by shaping the trailing edge of the modulator pulse a duration of about 2 msec. can be obtained.

The comparison of the γ-ray outputs of electron synchrotrons working at energies of about 300 MeV. has been done in two ways. One method consists of measuring the number of 'roentgens' observed on the axis of the beam at a distance of several metres, using a Victoreen ionization chamber surrounded by a thimble of lead ⅛ in. thick and expressing the axial intensity in roentgens per minute at one metre. The Glasgow machine can produce a steady output of 2,000 r./min. The other method makes use of a large ionization chamber with walls of copper 1 in. thick, this thickness being chosen to provide maximum electron shower intensities for 300-MeV. γ-rays. Such a chamber has been calibrated at Cornell University in terms of the number of equivalent quanta per coulomb of collected charge. The number of quanta measured by this chamber depends on the angular width of the beam, which is controlled by an aperture in a lead collimator. On the basis of the Cornell calibration of an identical chamber, the synchrotron has an output of $2 \times 10^{9}$ equivalent quanta per minute through an aperture of diameter ¼ in. situated 125 cm. from the target.

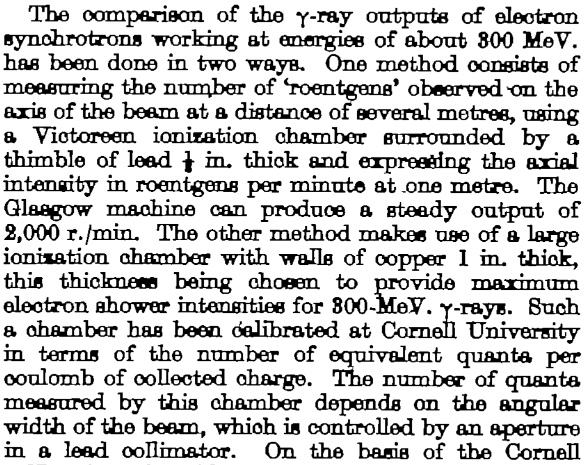

Fig. 4. Component parts of the vacuum chamber: a plain and a port sector fitted together, and a resonator

A project of this magnitude necessarily involves such a large number of workers that space permits an acknowledgment of only the principal contributors to the success of the installation. Throughout the development and constructional stages, the project was controlled by a committee under the joint chairmanship of Prof. P. I. Dee and of Mr. F. R. Perry, of the Research Department, Metropolitan-Vickers Electrical Co., Ltd. The members of the committee were drawn from the University, many departments of Metropolitan-Vickers, the Atomic Energy Research Establishment, Harwell, and several industrial firms responsible for the manufacture of different parts of the project. The magnet was designed by J. B. Hansell and the measurements and adjustments were supervised by E. A. Finlay. D. W. Fry, F. K. Goward and R. Carruthers, all of Harwell, who had been associated with the construction of the first successful electron synchrotron, were members of the committee. The ceramic vacuum chamber and resonators were manufactured by Steatite and Porcelain Products, Ltd., with the co-operation of R. Carruthers, who was also responsible for the design and manufacture of the radio-frequency and other electronic circuits. The electron guns, the prototype of which was designed at Harwell, have been modified and improved by A. C. Robb and J. T. Lloyd, of Glasgow. The task of designing the magnet corrections and of finding and improving the beam was the work of the authors of this article. A more complete report of this work will shortly be published elsewhere.

---

# DEFINITION OF THE SECOND OF TIME

By Sir H. SPENCER JONES, K.B.E., F.R.S.

WITH reference to the letter by Sir Edward Bullard, published in *Nature* of August 13, p. 282, the General Assembly of the International Astronomical Union, held in Dublin in September, passed a resolution approving the definition of the second proposed by the Comité International des Poids et Mesures, as follows:

"The second is the fraction 1 : 31 556 925·975 of the length of the tropical year for 1900·0."

This fraction is sufficiently accurate for all practical purposes, but it should be noted that the more precise value required for exact agreement with Newcomb's Tables of the Sun is 1 : 31 556 925·97474.

The physicist and the radio engineer will desire to know how the mean solar second of to-day can be related to the second, adopted as the unit of time in the above resolution. The following explanation has therefore been prepared by Commission 31 (Time) of the International Astronomical Union:

Mean solar or Universal time, based on the rotation of the Earth, is obtained in practice from observations of stars. Ephemeris time, basically the independent variable of the equations of motion of celestial bodies, is the time argument of astronomical ephemerides. The second of Ephemeris time is the unit of time defined in the resolution passed by the International Astronomical Union. The comparison of ephemeris positions of suitable celestial bodies with observations recorded in Universal time serves to obtain the difference $\Delta t$, Ephemeris time minus Universal time.

In practice, Ephemeris time is determined as the time at which an observation of the Moon is in agreement with the lunar ephemeris constructed in conformity with the internationally adopted solar ephemeris. For the years 1952–59, this lunar ephemeris is published in the volume "Improved Lunar Ephemeris, 1952–1959"; from 1960 onward it will be published annually in the National Ephemerides.

In order to obtain a frequency $\nu_E$ corresponding to the invariable unit of time defined in the resolution, the following steps are required:

(*a*) The frequency $\nu_U$ is obtained by using as unit of time the second of Universal time provided by wireless time signals issued by the national time services.

(*b*) Corrections to these time signals, obtained afterwards from observations of stars, are published regularly by the time services. Inter-comparisons of the time signals transmitted by the various observatories are published annually by the Bureau International de l'Heure.

(*c*) Values of the difference $\Delta t$, Ephemeris time minus Universal time, applicable to the middle of each year, are being published with a lag of from two to three years. They are at present derived from observations of occultations of stars by the Moon, and meridian observations of the Moon. It is expected that in the near future a programme of observations with dual-rate Moon position cameras, developed by Markowitz at the U.S. Naval Observatory, will provide a method of deriving the difference $\Delta t$ more accurately and more promptly.

(*d*) Let $D\Delta t$ designate the change per annum in the value of $\Delta t$, derived by a suitable formula for numerical differentiation from a sequence of annual values of $\Delta t$. If $\Delta t$ is expressed in seconds, the frequency $\nu_E$ corresponding to the second defined in the resolution is then obtained by:

$$\nu_E = \nu_U\left(1 - \frac{D\Delta t}{31{,}556{,}925{\cdot}975}\right)$$

$$= \nu_U\,(1 - 3{\cdot}1689 \times 10^{-8}\,D\Delta t)$$

(*e*) After the frequency of an atomic frequency standard has been determined to sufficient accuracy with respect to the second of the resolution, the atomic standard may be used to make the second immediately available.

The astronomical determinations of time are complicated by seasonal variations in the rate of rotation of the Earth as well as by the polar motion. These causes contribute to the discordances among the determinations of time at various observatories. Definitive corrections for these effects can at present be effected only with a lag of several years. Provisional corrections can, however, be applied at once, with a resulting uncertainty in Universal time at most of the same order as the uncertainty in the annual values of $\Delta t$.

Laboratory determinations of frequencies corresponding to the varying second of Universal time may aid importantly in the study of the seasonal variations in the Earth's rate of rotation.

When the relationship between the mean solar second at the present time and the second defined in the resolution of the International Astronomical Union has been satisfactorily determined, the cæsium frequency standard developed at the National Physical Laboratory will enable the mean solar second in future years to be related immediately to the fundamental unit of time.

As Sir Edward Bullard remarks, the atomic frequency standard will provide a check within a few years whether or not there is any divergence between astronomical and atomic time, and will thereby provide a test of the theories of Milne, Dirac and Jordan.

# WELSH PLANT BREEDING STATION

## NEW HEADQUARTERS AND EXPERIMENTAL GROUNDS

By PROF. E. T. JONES

Director

THE new headquarters and experimental grounds of the Welsh Plant Breeding Station at Plas Gogerddan were opened by H.M. The Queen, who was accompanied by H.R.H. The Duke of Edinburgh, on August 8 in the presence of more than one thousand guests.

Founded in 1919 as a research department of the University College of Wales for the investigation and improvement of farm crops, the Station owes its existence to foundation gifts to the College by Lord Milford of Llanstephan House, Radnorshire. Apart from these initial gifts, the research programme is supported financially by Treasury grants made by the Ministry of Agriculture, Fisheries and Food on the recommendation of the Agricultural Research Council.

The primary activities of the Station concern the breeding and development of new strains and varieties of grasses, clovers and oats. Valuable contributions to British agriculture have been made by the staff in the production of new varieties of farm crops, the development of new techniques in the establishment, manuring and management of grasslands, and the improvement of hill pastures. The Station has also carried out researches in seed-growing techniques, and has introduced seed-crop inspection and certification schemes. The aim of these is to ensure that the Station-bred strains are made available to farmers as authentic seed of the highest standard of purity. Much of this pioneer work has been of the greatest value in relation to the problems of grassland scientists in many parts of the world.

Plas Gogerddan became the new home of the Station when the University College of Wales purchased a major portion of the Gogerddan Estate in 1950. With the aid of funds provided by the University Grants Committee, the mansion (Fig. 1) has been renovated and converted into laboratories for chemistry and cytology, library, conference and common rooms, and offices for administrative and other staff. Residential quarters for the Director, or a senior research officer, and for a caretaker are also available.

Capital grants for the construction of greenhouses, field laboratories and the Lord Milford Plant Research Laboratories have been provided by the Ministry of Agriculture, Fisheries and Food. The new greenhouses, which are of cedar wood and of standard design, are in three separate blocks built to meet the needs of the Grass, Clover and Cereal Breeding Sections, respectively. A supplementary unit with lighting and heating equipment is provided in the Grass Breeding Section for the control of the flowering period in plants used for hand-crossing, and a central service block houses the boilers, soil sterilization units, potting benches and other ancillary equipment.

The heating of the greenhouses is by low-pressure steam raised in a locomotive-pattern boiler, which is automatically fired by a solid fuel underfeed stoker. Steam is carried by mains to pipe coils in the greenhouses and by branches from the mains to feed a calorifier in each of the laboratory blocks. The calorifiers consist of a cylinder with an inner heating coil, and by means of an electrically operated pump the steam-heated water in the cylinder is circulated through the laboratory radiators. These are arranged to give an internal room temperature of 60° F., with an external temperature of 30° F., and a low-pressure hot-water flow temperature of 180° F. Each calorifier is fitted with a thermostatic valve on the steam supply connexion, with steam trap, strainer and check valve. The steam boiler also provides steam to service two steam grids each 5 ft. square for soil sterilization, and steam jets for pot sterilization.

The field laboratories, which are adjacent to the greenhouses, consist of one-story units of simple and essentially functional design. In addition to office and laboratory rooms for scientific and technical

Fig. 2. Lord Milford Laboratories

*Topical Press*

staff, there are facilities for students and overseas workers to pursue training in plant breeding or schemes of research in collaboration with the Department of Agricultural Botany for higher degrees of the University of Wales.

The Lord Milford Laboratories (Fig. 2) have two floors and a basement and provide a total floor space of about 12,000 sq. ft. This building is built of brick with a rough-cast exterior and reinforced concrete floors surfaced with 'Accotiles'. It provides storage for cereal breeding material and herbage seeds, as well as laboratories for the Cereal, Seed Multiplication and Grassland Agronomy Sections. In the basement there are rooms for the long-term maintenance under controlled low-temperature conditions of special stocks of breeders' material, rooms with controlled lighting for the study of plant reactions to light, a boiler room and facilities for the threshing of oats and other grains.

By arrangement with the University College Estates Committee, adaptation and repairs to the farm buildings are in progress for the housing of cattle required for the field experiments, and for the installation of a series of three 'Unitherm' driers for the determination of the dry matter content of herbage samples. The hunter stables and coach houses have been converted into shops for the carpenter and mechanics and to house farm implements and farm machinery.

The home farm of Plas Gogerddan extends over approximately 200 acres, which, with the retention of the Frongoch Experimental Farm of 96 acres and the release of Brynamlwg Farm to the University College, leaves a net gain of more than 120 acres highly suited to the development of large-scale field experiments.

Multiplication of foundation seed of bred strains will continue to be undertaken at Morfa Mawr, a farm of 460 acres on the coast eleven miles south of Aberystwyth. Apart from an initial grant for stocking and the installation of seed-cleaning machinery, this farm, which is let to the Station by the University of Wales for seed-growing purposes, receives no financial assistance in respect of maintenance and capital expenditure.

A new Hill Nursery of 45 acres recently made available will provide facilities for the study of the behaviour and relative growth of herbage, cereal and *Brassica* breeding material under semi-upland conditions, and for the comparison of plant growth under the latter conditions with that at a lowland centre.

The new headquarters and experimental grounds provide excellent facilities and make an ideal centre for the immediate and future development of the Station's research programme.

# FUNGI IN FORESTS

IN a joint session with Section K (Botany) of the British Association, Section K* (Forestry) organized a discussion, held on the morning of September 5 in Bristol, at which the subject of "Fungi in Forests" was considered. Prof. Lily Newton was in the chair. The first of the four papers, that by Dr. I. Levisohn (Bedford College, London) on ways of studying the activity of mycorrhiza-formers in the soil, emphasized the difficulty of proving the relationship between the fungal and tree partners in mycorrhizæ of forest trees and commented on the fact that few, if any, endotrophic mycorrhizal fungi of trees have been isolated. Isolation of the fungus from ectotrophic mycorrhizæ has been achieved in a number of instances: by isolation from the fungal sporophores; by direct isolation from the mycorrhizal roots; and from hyphal strands or rhizomorphs directly connected with the mycorrhizæ. Identification of the fungus can often be made through comparison of mycelial cultures taken from the mycorrhizal roots with those from sporophores of known species. Inoculation of isolates on to tree roots is also desirable.

A number of known mycorrhiza-formers have been studied in the free-living state in field and pot experiments, and lively growth has been observed on a variety of decomposing organic material. Certain mycorrhiza-formers, such as *Boletus scaber* and *Rhizopogon luteolus*, have been shown to be capable of influencing root morphology and shoot development of a variety of tree species even when contact, and consequent formation of mycorrhizæ, was prevented. Pine roots responded by forking, and monopodial systems developed in larch and spruce roots. These ectotrophic mycelia also stimulated seedling growth of certain species of tree in which the mycorrhizæ are normally endotrophic—for example, Lawson cypress, *Thuja* sp. and *Robinia pseudacacia*. *Robinia* normally has both endotrophic mycorrhizæ and root nodules inhabited by nitrogen-fixing bacteria. Inoculation with either crushed nodule material or *Boletus scaber* gave improved growth of the seedlings.

Dr. Lilian E. Hawker (University of Bristol) then read a paper on hypogeous fungi, in which she gave an account of the collection of truffles and other hypogeous fungi by members of the Department of Botany, Bristol. The Bristol area was well worked by Broome some hundred years ago, so that it is not surprising that few new British records and fewer new species have been added to the list. The mature fruit bodies of ascomycetous (Tuberales, Plectascales), basidiomycetous (Hymenogastrales) and phycomycetous (*Endogone*) hypogeous fungi are strikingly similar and consist of a central sporogenous mass, or gleba, and an outer rind or peridium. These give little clue to systematic position; but comparison with less complex species and, above all, developmental studies have established the relationships of most species. Nevertheless, development has been followed in a comparatively few species, and modern work, particularly in France, suggests that the hypogeous Basidiomycetes, in particular, may be a very heterogeneous collection containing both simpler and reduced forms of diverse relationship. Dr. Hawker illustrated this with a series of lantern slides and by a demonstration of drawings, specimens and microscopic preparations.

Owing to the great difficulty of culturing most of these fungi, direct proof of mycorrhizal relationships with higher plants is lacking, but constant association between certain species of hypogeous fungi and certain trees is suggestive. For a similar reason, no exact physiological experiments have been done with cultures proved to be of hypogeous fungi, but identical isolates from mycorrhizæ of beech and fruit-bodies of *Tuber* spp. have shown nutritional characters similar to those of known mycorrhiza-formers. Since well over a thousand separate collections have been made during the past five years, the commoner species have occurred many times. Data of tree cover, soil and weather conditions were recorded for each collection, so that some idea of the factors controlling distribution of the commoner species has been obtained. Thus, while the majority are favoured by alkaline soils, a few—such as *Elaphomyces granulatus* and *Rhizopogon luteolus*—are found mainly in more acid situations. A well-aerated soil is essential for all species, although some are more exacting than others. Fruit-bodies, however, frequently form in contact with hard surfaces such as roots, path edges or clay layers. Both temperature and soil moisture are important factors in fruit-body initiation and maturation, although some species are more tolerant of drought and cold than others.

Miss R. M. Godfrey (University of Bristol) discussed some woodland species of *Endogone*. Arising out of the work described in the previous paper, Miss Godfrey has made a special study of the interesting phycomycetous genus *Endogone*. This genus includes forms producing zygospores, as a result of conjugation between gametangia, in groups within a loosely constructed fruit-body, and others producing similar fruit-bodies containing only chlamydospores. A single example was described by Thaxter of a species in which the fruit-body contained both types of spore, thus justifying the inclusion of the chlamydosporic forms in the same genus. Miss Godfrey was able to show slides of a specimen found by her at Cleeve Coombe, Somerset, believed to be a fruit-body of the normally chlamydosporic *E. microcarpa* containing a number of zygospores scattered among the typical chlamydospores.

British records, hitherto, have been limited to the zygosporic *E. lactiflua* (with a single doubtful and unsubstantiated reference to the zygosporic *E. pisiformis*), and the two chlamydosporic species, *E. microcarpa* and *E. macrocarpa*. To these Miss Godfrey has added an undoubted specimen of *E. pisiformis* collected by Dr. J. Fraymouth in the New Forest and two species in which the chlamydospores show characteristic grouping, believed to be *E. fuegiana* and *E. vesiculosa*. The great variability of spore characters shown by *E. macrocarpa* was also pointed out. The genus *Endogone* is of interest both from the systematic and biological points of view. The zygosporic forms show affinity both with the Mucorales, with which they are provisionally classified, and the Hemi-Ascomycetes. If zygospores could be germinated the results would be of primary significance, since, if on germination they gave rise to a sporangium, their relationship with *Mucor* would be established; but if they should germinate by the formation of endogenous spores, they might be considered to have a closer affinity with the simple Ascomycetes. Unfortunately, no one has as yet succeeded in inducing germination of zygospores by any of a large number of techniques. Miss Godfrey, however, was able to report germination of chlamydospores of both *E. microcarpa* and *E. macrocarpa*. These germinate to produce a typical coarse mycelium with characteristic branching.

In conclusion, Miss Godfrey pointed out that a study of the mycorrhizæ of plants growing near the *Endogone* fruit-bodies (including yew and species of *Viola*) did not yield any conclusive evidence in support of Peyronel's thesis that *Endogone* spp. are the endophytes forming the vesicular-arbuscular type of mycorrhizæ with various flowering plants.

In the final paper, Prof. C. G. C. Chesters (University of Nottingham), speaking on the fungal population of bark of living trees, recalled the fact that when a branch of a tree is shed, either from natural causes or through forestry practice, it is rapidly colonized by one or more microfungi. Such fungi may be termed the flora of 'first incidence'. Whole saplings may be colonized with a single bark-inhabiting fungus such as *Diaporthe leiphemia* on beech, or a number of these may occur. Some are confined to a single tree species—for example, *Diatrype disciformis* on beech—while others may be termed 'plurivorous'—for example, *Valsa ambiens*. Such a constant association between certain species and the bark of dead tree branches suggests that the inoculum must already be present on the living tree before the branch is shed. Washings of bark of various trees yielded spores of these species, but there was a predominance of spores of such species as *Pullularia pullulans* and *Cladosporium herbarum*. With repeated washings the proportion of spores of these species increased. Examination of fissures in the bark and of lenticels showed the presence of chlamydospores and mycelium. It is of interest that Smit and Wieninga (1953) also obtained *P. pullulans* from washings of dead leaves, and it is likely that this fungus is concerned in pectin decomposition.

In the discussion, unfortunately limited by the time allowed, which followed each of these papers, Dr. J. Ramsbottom and others emphasized the change in our concept of 'symbiosis'. Modern work supports the idea of a precarious balance, or controlled parasitism, between the two partners of a 'symbiotic' system.

# LANGUAGE, MEANING AND MIND

At the Bristol meeting of the British Association, a symposium on semantics was organized by Section J (Psychology). In Great Britain semantics has tended to remain a topic of philosophical parlour conversation, except among linguists for whom it has been rather a technical discipline. Among empirically minded scientists, especially psychologists—who are more severely empirical than any to-day—semantics has come to be regarded as a rather fancy line of talk devoid of both rigour and content. The aim of this symposium, in which the disciplines of psychology, linguistics, neurology and mathematical logic were represented, was to demonstrate not only a measure of common ground among these disciplines, but also to indicate that semantics is now sufficiently developed to provide psychology with a much-needed methodological instrument. It is an instrument with applications as far-reaching and precise as those of statistics, and is, indeed, a necessary complement to the latter if figures are to have meaning. Moreover, it is not without its bearings on the hotly debated theme of the "Fragmentation of Science" so provocatively presented at Bristol by Mr. Ritchie Calder.

In the opening paper on "Semantics in Relation to Psychology", Prof. G. P. Meredith traced in outline the history of the 'theory of signs' from its early beginnings in Greek medicine down to its present systematic development in the hands of Morris and Carnap. The signifying function of words is seen as an instance of a much wider semantic phenomenon, namely, the interpretation of signs of all kinds. This communication of meanings is a fundamental biological process essential to animal societies. To clarify this study of 'semiotic', as it is called, Morris, following Charles Peirce, has divided it into three main branches: syntactics investigates the relations of signs among themselves; semantics deals with the relations of signs to the objects signified; and pragmatics is concerned with the relations of signs to interpreters. These divisions, which correspond with the famous triangle of "Thought, Symbol and Referent" of Ogden and Richards, are represented in Fig. 1. Thus relations are the essential theme of semiotic studies. A word bereft of relationship is a mere physical event.

Carnap has developed semantics in terms of symbolic logic. In a highly abstract system he has presented the pure mathematics of language. This system, though lacking immediate applicability, may well be needed in the future society of universal and virtually instantaneous polyglot communications. Carnap will play Riemann to some future Einstein of social space-time.

Meanwhile, the discipline of semantics as developed by linguists can provide psychology with valuable discriminations. Ullmann, in his "Principles of Semantics", provides a three-dimensional classification of the fields of linguistic inquiry based on: the level of complexity (as in phonology, lexicology and syntax); the transverse or longitudinal aspect of language in time (synchronistic or diachronistic); and forms or meanings (as in morphology and semantics). If we extend this treatment to visual as well as auditory signs, we have the 'semiotic cabinet' of Fig. 2.

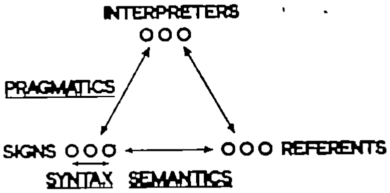

Fig. 1. The semiotic triangle

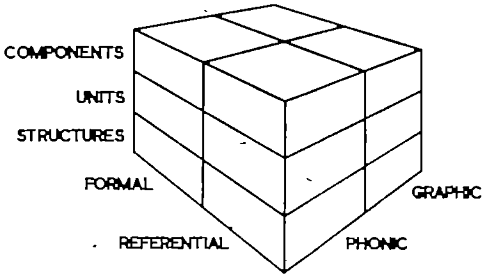

Fig. 2. The semiotic cabinet

Such schemes can suggest valuable frameworks for the design of psychological experiments and studies of such problems as aphasia as well as normal linguistic development in childhood. They can help to resolve the many terminological problems which beset psychology, and also to break down the barriers of jargon which hinder its relations with other sciences. Finally, the fundamental difficulties which arise from the categoreal diversity in thoughts, words and things, and from the 'systematically misleading expressions' discussed by Gilbert Ryle, may, through semantic analysis, give way to a system of empirical type-differences, a system urgently needed in modern psychological theory.

Prof. Stephen Ullmann, in his paper on "The Concept of Meaning in Linguistics", took his stand (appropriately enough in a psychological symposium) on the non-self-sufficiency of linguistics for resolving the nature of 'meaning'. Psychology and neurology, philosophy, anthropology and social science, all have a stake in this problem. He discussed two main approaches to the problem, the analytical and the operational, and showed that these are ultimately more complementary than contradictory.

Discussing the triangle of Ogden and Richards, in which the relations between the 'name', the 'sense' and the 'thing' are expressed, Prof. Ullmann simplified the issue by dismissing the 'thing' as non-linguistic. We thus are left with a binary and reciprocal relation between the name and the sense. The speaker starts with the sense. In him the sense calls up the name. The hearer starts from the name, and in him the name calls up the sense. The link between name and sense is severed only in the brain lesions studied by neurology. An over-simplified view which asserts some direct relation of designation between the name and the thing creates insuperable difficulties by ignoring the way in which language, in fact, works. The word 'atom' does not mean to-day what it meant to the Greeks, though the atom itself has not changed.

It is the concept which has changed. A more serious objection to the analytical dichotomy of sense and name is that it seems to imply a mysterious psychophysical relation. There certainly is an inherent duality in language or in any sign-system, between the sign and that which is signified; but name and sense are not, in fact, heterogeneous. The name is not the physical event but the mental impression of the word. Both name and sense are mental phenomena.

There are weaknesses in the analytical view. One is the fact of polyvalency. One name may have several senses. One sense may be expressed through several names. The view thus needs elaboration. More fundamental is the objection that the view is atomistic and fails to account for the all-important determination of context. Every word has its 'associative field'. There are associations between names and between senses, and the two may intersect. This complex phenomenon is being resolved into manageable parts by the notion of semantic fields—for example, the scale of colours. (It may here be pointed out that the effective semantic fields are, in fact, the various branches of science.)

As the analytical view widens to accommodate the facts of language in operation, it approaches the operational view. On this view the meaning of a word is not what we say about it, but what we do with it. Wittgenstein, not without some reservations, identified the meaning with the use of the word. On this view meaning is not revealed by use, it is itself the use. Thus the influence of context, which is embarrassing to the analytical view, is the very basis of the operational view. Words apart from context are abstractions. The operational view is thus closer to the facts of language in action. However, we do use dictionaries, and the lexicographer, though starting operationally from linguistic facts, finishes with an analysis of discrete meanings. Thus the analytical view has its part to play. Words have been likened by Wittgenstein to tools, and by de Saussure to chessmen. Both similes suggest a range of relationships, a 'field of force', facilitating a structural view of language. Such a view can do much to facilitate the relations between linguistics and the neighbouring disciplines.

Sir Russell Brain revealed the intricacy and subtlety of the problems thrown up by neurological disturbances in his paper on "The Semantic Aspects of Aphasia". The difficulty of the linguists in finding an adequate definition for the term 'word' is matched in neurology by the difficulty of finding a firm physiological substratum the behaviour of which, both in order and disorder, can account for all the elusive phenomena of aphasia. Here again, the determining role of context is in sharp evidence. Also the neurologist has to be on his guard against being misled by his own language in formulating both the symptoms and the problems.

In aphasia words become less available for use, in varying degrees. The patient may fail to produce a word on request, but may say it under stress of emotion, or in another context. Also, he may recognize it when presented to him and reject wrong alternatives. Or he may have very few words available and yet contrive to use them, with or without gestures, to convey a correct answer to a question. Formulating a proposition is thus partly independent of particular words; and thinking, though in the long run very much dependent upon command of language, may go on in spite of word-failure. In some cases the choice of words becomes 'liquid', one word masquerading for another—for example, a more general for a more specific word. Or again, the word may be heard as a meaningless sound. Analogous failures occur in speaking, reading and writing.

In every word there is a constant element and two variable elements. On one hand the word as heard may vary in pitch, volume, pronunciation or intonation; on the other hand, it may enter, through sentences, into many different contexts, having numerous associational meanings. Between these variables of sound and meaning there must exist a constant pattern, a fixed atomic element. The term 'auditory word-schema' is given to this fixed element. The schema is conceived as a physiological disposition: it does not itself enter consciousness, but it does determine verbal awareness.

From reading, again with its variety of visual forms, we similarly have for each word a 'visual word-schema'; and on the expressive side we have motor schemas for speaking and writing. These schemas functioning together give us a 'central word-schema'. This theoretical framework of the central schema related through receptive and expressive schemas to incoming and outgoing language, and, through associative links, to meaning and thought, provides a physiological basis for the very diverse disturbances of language, from the most specific and superficial to the most serious and far-reaching disorders. In these last the central word-schemas are disorganized, and the capacity to evoke meanings has gone. Thought is thus inevitably impaired. In the more superficial disorders, involving one channel of communication only, thinking may not be much affected. These verbal schemas, however, being physiological, and therefore unconscious, may, through their evocation of meanings, play a part in what, to consciousness, is 'non-verbal' thinking. When schemas are damaged, the effects may not, therefore, be confined to linguistic behaviour only. In the normal state they play their part in the facilitation of apparently non-verbal thought-processes.

In the concluding paper of the symposium, on "Semantics, Pragmatics and Behaviour", Dr. F. H. George made a plea for a more sophisticated view of semantics than the popular notion that identifies it with merely being careful to define our terms. Language can be reconstructed according to systematic rules. Taking a behaviourist point of view, he located the phenomena of 'meaning' firmly in the organism. Thus private introspective statements can be used scientifically only in so far as they are clearly associated with statements concerning public data. But the latter often misses the core of behaviour, whereas the former appears more relevant. The psychologist must reconcile the two worlds or, in other words, the two languages. Only through rigorous formalization can the inconsistencies between the two be eliminated. Statements within a theory must be distinguished from statements about a theory. Philosophical statements are statements by philosophers, that is, they are the linguistic behaviour of certain organisms. As such, they are subject-matter for psychology. Conversely, the statements of psychologists present formal characteristics which can be analysed and clarified by philosophers. Through this twin activity of pragmatics (studying the use of signs by organisms) and semantics (studying the reference of signs to objects), both under the formal discipline of logic, psychology can look forward to healthy progress.

# NEWS and VIEWS

## Mr. G. A. Stewart, M.B.E.

MR. G. A. STEWART, assistant secretary and librarian of the Royal Society of Edinburgh, is retiring from his duties there on October 12 after more than fifty years of service. This service has been continuous except during the period of the First World War, when Mr. Stewart participated as a member of the Royal Scots in the campaigns in Gallipoli, Palestine and France, and was "mentioned in dispatches". Public recognition of the value of his work to the Royal Society of Edinburgh was afforded recently by the award of the honour of M.B.E. Only the senior officers of a scientific society, however, really know what a boon it is to have constantly at hand a capable and conscientious guide for every question, major or minor, on which decision must be taken. The devotion and experience of Mr. Stewart have indeed proved of inestimable assistance to the Council of the Royal Society of Edinburgh since the time of Lord Kelvin. Best wishes will be accorded him, not only by Fellows of the Society itself, but also by many members of other bodies whom he has cheerfully aided with loans of books from the extensive library under his charge, for happy years of well-merited leisure in his retirement and of success in his favourite sport of fishing.

## Virus Studies in The Queen's University, Belfast

AFTER the appointment of Dr. G. W. A. Dick to the chair of bacteriology (now called microbiology) at The Queen's University of Belfast, it was decided that virus work would be undertaken in the Department. The University undertook considerable alterations of the existing accommodation in order to provide a virus laboratory with a sterile room, hot room, etc., and also animal accommodation. In addition, a grant of £3,000 was made by the University to assist in equipping the Department for bacteriology and virus work. Since no virus work had previously been done in Northern Ireland, a considerable amount of basic equipment had to be obtained, and a grant of 21,000 dollars has been made for this purpose by the Rockefeller Foundation. This money is being used to purchase, among other things, a 'Spinco' centrifuge, an 'International' refrigerated centrifuge, a −70° C. storage box, a cage sterilizer, a water demineralizer and microscopes.

Two lines of virus research work are going to be undertaken. One of these is concerned with the problem of latent virus infections based on the mouse hepatitis model (Gledhill and Dick, *J. Path. and Bact.*, **69**, 311; 1955) and the other is on poliomyelitis. To assist with this latter study, the National Foundation for Infantile Paralysis has awarded a research fellowship to The Queen's University which is being filled by Dr. D. Surrey Dane, and a salary has been provided for a technical assistant, Miss M. Briggs. The poliomyelitis research has started with the co-operation of Dr. W. J. McLeod and county medical officers of health in an epidemiological study of the distribution of antibody to poliomyelitis in the north of Ireland. The latent virus studies are not yet commenced. When the above research projects are under way, it is intended that a diagnostic virus laboratory will also be established, which will assist in diagnosis and in epidemiological studies of virus diseases in the north of Ireland.

## British Colonial University Institutions

IN a pamphlet entitled "Foundations of Freedom: the New Universities Overseas" (British Commonwealth Affairs No. 10; pp. 19. London: Longmans, Green and Co., Ltd., 1955; 1*s*. 6*d*. net), Sir James Duff makes some interesting comments on progress since the Asquith Commission on Higher Education in the Colonies reported in June 1944. The pamphlet also supplements the recent review by the Inter-University Council for Higher Education Overseas. Sir James stresses the need for a balanced system and the way in which technical colleges, under the title of colleges of art, science and technology, are being fostered to bridge, for the present, the gap that exists in the Colonies between secondary school and university. So far, the Inter-University Council has succeeded in keeping a clear dividing-line between these colleges and the university institution; and at Fourah Bay College, Sierra Leone, where both university and technical work have been included, there seem to have been real advantages. The difficulty in recruiting worthy staff has not materialized, largely because very hard and effective work at the Council's London office has ensured the finding of good recruits and their subsequent promotion on return to Great Britain. The number of students is growing steadily, and most British universities tend to limit their quota of Colonial students to those seeking higher degrees or studying subjects not available locally. Sir James stresses the part which the graduates of the Colonial university institutions must play in supplying the intelligent leadership which the Colonies need as they advance towards self-government and its importance if the institutions are to maintain high standards and academic autonomy. He notes, too, the financial problem set by the high cost of the colleges, capital and recurrent, and the low national income of the territories concerned, and questions the soundness of such decisions as that to build a hospital and medical school at Ibadan to satisfy the training requirements of the University of London. Sir James believes that the suggestion he advanced as a member of the Asquith Commission, that each Colonial university college should establish a relation with a specific university in Great Britain and work for the degrees of that university until it reaches university status and grants its own degrees, would have facilitated the maintenance of high standards and greater flexibility in the arrangements needed in these early years; in particular, two-way traffic and a wider distribution of Colonial students in British universities would have been possible.

## Tree Root Development on Upland Heaths

THE planting of heathlands with trees has always proved a tempting subject to the forester on the Continent of Europe as well as in Great Britain. Some research work at the instance of the Forestry Commission, especially in connexion with the rooting of coniferous trees on upland heaths, was carried out between November 1951 and April 1953, at selected forest areas in north-eastern England and Scotland, and has now been described by C. W. Yeatman in Forestry Commission Bulletin No. 21, "Tree Root Development on Upland Heaths" (pp. 72+24 plates and diagrams. London: H.M.S.O., 1955; 1*s*. 6*d*. net). There are considerable areas of this type of land available in Britain. The object of the investigation was to determine: the relationships existing between the development of the root systems, the soils, and the types and intensities of cultivation prior to planting; the effects of the application of fertilizers on the vigour of the root systems; differences occurring in the root systems of the species studied; and the comparative ability of the root systems of these species to exploit the soil both in their natural state and when cultivated. An upland heath has been defined as "A Callunetum on shallow peat in which the roots of the vascular plants penetrate into the sub-peat layer". The peat is commonly two to four inches thick. Notes are given on the distribution of these heaths and the methods used, the findings, and the conclusions of an investigation into the root development of the principal conifers used extensively by the Forestry Commission in the north of England, such as Japanese larch, Scots pine, Sitka spruce, lodgepole pine and Corsican pine.

### Systematics Association: Meeting in Edinburgh

A MEETING of the Systematics Association was held at the Royal Botanic Garden, Edinburgh, during September 16–17. The three sessions were devoted respectively to the criteria of species, genera and families. Each session had a single main paper followed by general discussion, the principal speakers being Prof. I. Manton (species), Prof. T. G. Tutin (genera) and Mr. E. J. H. Corner (families). The meeting took its lead from the very beautiful electron micrographs of minute structure in the flagellate *Chrysochromulina* shown by Prof. Manton, and the prime necessity for accurate and detailed factual knowledge was emphasized at all three discussions. Two other themes also recurred: first, the difficulty of incorporating new types of data into the classification unless such data cover the whole geographical and taxonomic range of the unit under study; secondly, the need for continued availability of the old categories in an aggregate sense, even when research has shown their subdivision to be necessary in critical work. The meeting terminated with a visit to the new establishment of the Scottish Society for Research in Plant Breeding.

Among those attending the meeting were students from a vacation course in practical taxonomy which had just been given in the University Department of Botany at Edinburgh, and Dr. P. H. Davis outlined the scope of this course during an informal soirée on the Friday evening. Following lectures on some important aspects of herbarium work, the students had been set to revise small groups of Mediterranean species. The course made full use of the excellent herbarium and library facilities at Edinburgh, and was intended to fill a gap which must often arise in botanical teaching elsewhere.

### Bibliographical Survey of Flexure Devices

THE British Scientific Instrument Research Association has started to publish a series of bibliographical surveys on instrument parts, and the first of this series is entitled "Flexure Devices", by P. J. Geary (pp. 44; from the Association at Chislehurst, Kent; 1955; 10s. 6d.). It is a booklet comprising an illustrated technical introduction, digests of twenty-eight selected texts of major importance, an annotated list of one hundred and eleven references to texts of secondary importance, supplementary references and a name index. The period covered by the survey is from 1900 to the present. Periodical, book and report literature has been searched methodically, but not patent literature, although digests of some patent specifications have been included. No claim is made to complete coverage. Flexure devices take many forms, and for the purpose of the survey they have been grouped under the six headings: flexure pivots, parallel movements, twin strip mechanisms, buckling strip devices, rolling suspensions and the sine spring. These are described in some detail in the technical introduction, and their advantages and limitations are mentioned. Reference is made to the general use of flexible strips in gauging instruments following their introduction in about 1916 by the Metrology Department (now Division) of the National Physical Laboratory, Teddington, and to the forthcoming useful review, "The Application of Spring Strips to Instrument Design," to be published in the series of "Notes on Applied Science" of the National Physical Laboratory. The sine spring, a resilient member of adjustable stiffness, has been developed and applied by the Ministry of Supply.

### National Foundation for Scientific Research, Brussels: Annual Report

THE twenty-seventh annual report of the National Foundation for Scientific Research, Brussels (pp. 227; from the Foundation), covers the year 1953–54 and records a fourth grant, of 1,671,000 francs, to the Commission for Clinical Research. Of this, 350,000 francs went to the University of Ghent, 520,000 francs to the University of Liège, 345,000 francs to the University of Brussels, and 456,000 francs to the Catholic University of Louvain, chiefly for work on cortisone and the adrenocorticotropic hormone; lists of publications are appended to brief reports from each of these centres. Special grants made during the year include 200,000 francs for research on a scientific method of determining the mechanical characteristics of hydraulic cement; 250,000 francs for investigations on the physiology and pharmacology of the pulmonary circulation; and 750,000 francs for work on calculating machines in the university laboratories. Brief notes on the work on the utilization of radioisotopes at the Universities of Brussels, Ghent, Liège and Louvain, at the State Agronomic Institute at Gembloux, as well as in industry, are included. A further 2,000,000 francs was voted to the Interuniversity Microfilm Commission, and 100,000 francs for low-temperature research at the University of Louvain. Lists of recipients of grants for 1953–54 and of publications by recipients of grants during 1952–54 are appended.

### Queen Victoria Museum and Art Gallery, Launceston, Tasmania: Annual Report

THE annual report for 1953–54 of the Queen Victoria Museum and Art Gallery, Launceston, Tasmania (pp. 7; from the Museum; 1955), indicates progress in many directions. The vertebrate gallery has been reorganized, new displays have been completed in the new anthropological gallery, a new series of Tasmanian fossils has been placed on exhibition, the water-colour gallery has been re-hung, and photographic copies of certain paintings made available for art historians. The matter of public relations has been one for serious attention, and there is ample evidence in the report that the services provided by the Institution are appreciated by the community.

### Classified List of Egyptian Scientific Papers

IN 1952 the National Research Council of Egypt started to compile and issue annual lists of research papers published in Egypt and by Egyptians abroad. The third volume has recently appeared (pp. 127; from the Council, Cairo) covering papers published in

1953, and includes more university theses than the first two volumes. Entries are arranged by subject according to the Universal Decimal Classification and alphabetically by the names of authors; in this latest volume the rules used in the "World List of Scientific Periodicals" have been adopted for abbreviation of titles of periodicals. There are an author index and a supplementary list of Egyptian periodicals.

## Science and Management: Conference in Harrogate

The British Institute of Management will hold its national conference this year at Harrogate during November 2–4, the general theme being "The Impact of Science on Management in the Future". Among the subjects to be discussed are: training science and engineering graduates for industry; electronic processing of data; development of tools of production; operational research; the research associations; automation; human implications of technical innovation; use of radioactive isotopes; and training scientists for management. Stress will be laid throughout the Conference on the need to translate new scientific discoveries into immediate and practical day-to-day effect. Twenty-four sectional meetings will be held during the two full days of the conference; these will be arranged so that five or six will be held simultaneously, and, in effect, delegates will be able to attend five meetings altogether, at each of which there will be a choice of about half a dozen topics. On the evening of November 3 there will be a choice of sixteen discussion groups, each devoted to a topic currently attracting widespread attention in management circles. Altogether about a thousand persons will be attending the conference. The fee is £9. Further information can be obtained from the Institute at Management House, 8 Hill Street, London, W.1.

## Fresh-water Biology in Scotland

A two-day meeting is being arranged for April 9–10, 1956, by the Institute of Biology (Scottish Branch), to be held in the Zoology Department of the University of Glasgow. There will be three half-days for papers and a half-day excursion to the University's Field Station at Rossdhu, Loch Lomond. The subjects will be: chemistry of fresh waters; plants as indicators of fish productivity; bottom fauna and bottom deposits; erosion products as affecting the river regime; fish parasites; molluscs; amphibia; trout; char; powan; pike; coastal migration of salmon; endocrines of salmonids; the work of the Salmon Inspectorate, that of the North of Scotland Hydro-Electric Board and that of the Brown Trout Research Laboratory, Faskally. Further information will be available in due course from Dr. R. M. Gorrie, "Balnagowan", Murrayfield Drive, Edinburgh, who is secretary of the Scottish Branch of the Institute of Biology.

## Announcements

We regret to record the death on September 29 of Prof. H. M. Turnbull, F.R.S., emeritus professor of morbid anatomy in the University of London, aged eighty.

Prof. P. M. S. Blackett, professor of physics, Imperial College of Science and Technology, London, and Mr. H. Douglass, general secretary of the Iron and Steel Trades Confederation, have been appointed members of the Advisory Council for Scientific and Industrial Research. Mr. J. Crawford, Prof. T. R. C. Fox and Sir George Thomson have retired from the Council on completion of their terms of office.

Mr. Stephen Cheveley, chairman of the Central Agricultural Control, Imperial Chemical Industries, Ltd., has been appointed by the Minister of Agriculture, Fisheries and Food and the Secretary of State for Scotland to be chairman of the Governing Body of the Foot-and-Mouth Disease Research Institute, Pirbright, Surrey, in succession to Prof. Wilson Smith, who is retiring.

A conference on "Raw Cotton—its Properties and Distribution" has been arranged by the Textile Institute and will be held in the Walker Art Gallery, Liverpool, on November 23. The speakers and their subjects are: Prof. S. C. Harland (University of Manchester) on genetics; E. Lord (British Cotton Industry Research Association) on cotton quality; Allan Draper (William Birtwistle Allied Mills, Ltd.) on spinners' requirements; and W. B. Hutchinson (Major Cleaver and Co.) on marketing. Further information can be obtained from the General Secretary, Textile Institute, 10 Blackfriars Street, Manchester 3.

A one-day symposium on chromatography will be held at Hatfield Technical College, Roe Green, Hatfield, Herts, on November 4. Four papers will be read, as follows: principles of chromatography (Dr. A. J. P. Martin), inorganic chromatography (Dr. F. H. Pollard), paper electrophoresis (Dr. A. B. Foster) and vapour-phase chromatography (H. N. Wilson). Tickets for the symposium are available on application to the College.

The British Institute of Recorded Sound, in conjunction with the Department of Extra-Mural Studies of the University of London, has arranged for six lectures to be given by Mr. Eric Simms on "The Language of Birds and other Animals". The first lecture was given on October 4, and the others will be given on alternate Tuesdays (7 p.m.) at fortnightly intervals from that date. The fee is 10*s.* the course or 2*s.* 6*d.* each lecture. On January 25 at 7.30 p.m., Dr. W. H. George will give a lecture (fee 2*s.* 6*d.*) on "Pianists' Touch—its Scientific Study". All the lectures will be at the Institute premises, 38 Russell Square, London, W.C.1, whence further information can be obtained.

The Department of Agriculture for Scotland has awarded the following postgraduate scholarships in husbandry, tenable for periods up to three years: A. D. Drysdale (University of Cambridge), Miss C. J. Falconer (University of Reading), David M. S. Livingston (University of Aberdeen and Low Temperature Research Station, Cambridge), R. A. N. Napier (University of Edinburgh) and Charles Smith (Iowa State College). In addition, the following current awards are being continued for a further period: I. C. Beattie, J. Frame and W. C. Smith (Massey Agricultural College, New Zealand), I. A. Munro (University of Reading) and T. M. Sutherland (Iowa State College).

The Association of British Chemical Manufacturers (Cecil Chambers, 86 Strand, London, W.C.2) has recently published "British Chemicals and their Manufacturers, 1955" (pp. 192), which lists about twelve thousand products with the names and addresses of the manufacturers. The book is available free to persons or firms interested in the purchase of chemicals on application to the Association.

# EDUCATION OF THE PHYSICIST

At the recent Bristol meeting of the British Association a recurrent theme in addresses to several sections was the specialist, and what should be done about him. Mr. J. F. Wolfenden, president of Section L (Education), spoke of the 'educated man' in 1955 as the man who could walk in the two great fields of thought, that of human aspirations and endeavour to which he would come through the humanities, and that of abstract thought and control over Nature to which man comes through science. Following him and speaking on the educated man in 1984, Dr. J. Bronowski threatened the world with Orwellian consequences if the schools and universities did not follow Mr. Wolfenden's advice; and Mr. Ritchie Calder, speaking as president of Section X (the Assembly of Corresponding Societies), accused scientists of knowing little in science itself outside each man's own speciality, and of being unable to achieve or communicate any broad picture of the state or meaning of science.

Mainly on this theme, a session on September 5 was organized jointly by Section A (Physics and Mathematics) and Section L (Education), devoted to the "Education of the Physicist", under the chairmanship of Mr. Wolfenden. The aims of the organizers were these: schools in Britain are frequently accused of over-specialization; Is this accusation just? Would anyone defend the present state of affairs? If the education of scientists is too specialized, where must we look for the remedy—to the schools or the universities? And would any remedies that might be suggested increase or decrease the number of boys who choose science? Finally, how, if at all, can we produce Mr. Wolfenden's educated man, the man who is equally at home in the humanities and in science?

The first speaker was Sir Philip Morris, vice-chancellor of the University of Bristol, who said that the central problem in education is the impact of the great increase in knowledge, particularly scientific knowledge, and its vastly increased importance. He feels that our primary education is notably successful, but that the secondary stage is the heart of our educational problem to-day. The idea of secondary education for all has caught men's imagination, as something we want and ought to have, but ideas as to what this education ought to be are shadowy, lacking coherent form and definite substance.

Interest in physics and the desire to make a career in the subject, or indeed in any other branch of science, normally show themselves during the secondary stage of a school education. The choice that a boy will make is partly a matter of natural aptitude, but partly a matter of the opportunities presented to him at school and the influences brought to bear on him. Sir Philip strongly emphasized how great is the influence of the secondary school, whether deliberate or not, in shaping the lives of the children who go there and in guiding them towards careers. He therefore thinks that a balance between the linguistic, the mathematical and the scientific is of the greatest importance during the first five years of the secondary school course, so that a child will have every opportunity to follow where his true abilities and ambition lie.

Sir Philip thinks that we have deviated more from a properly balanced education than we ought in these first five years. The problems that physicists in particular ought to ask themselves are: How vital is mathematical knowledge to the school child's appreciation of science? And should the sciences at this stage be taught as separate subjects? It is of the utmost importance that every secondary school pupil should learn about the scientist's outlook on the physical universe; Sir Philip placed this aim above, though not necessarily in opposition to, a preliminary grounding in particular scientific subjects.

In the last two or three years before the university, particular subjects chosen from those found in them must be followed seriously and deeply, but even so the course must have some balance. Much has been written on the educative value of a purely scientific education, and certainly really imaginative teachers can use science to provide for their pupils a full range of spiritual, emotional, social and political experience. But Sir Philip doubts the wisdom of making the attempt, and feels it better that science teachers should do their best to persuade their pupils of the importance of subjects outside their speciality and should leave it to others to teach these subjects.

Prof. N. F. Mott, Cavendish professor of physics in the University of Cambridge, spoke of his experience in interviewing candidates for admission to the University of Bristol when he was head of the Physics Department there, and the number of students who had said that, apart from their specialist studies, their curriculum included as little as one period of scripture, one of English, one of civics and one of gymnastics. Whether or not this was a fair description of the curriculum in many schools, it seems to him to indicate that in the boys' minds the subjects outside their specialization are treated with little respect. He believes that at least one arts subject, such as a modern language, should be continued seriously until the end of their time in the sixth form; and he believes that the sixth form rather than the university is the place where the basis of a general education should be laid. To widen the curriculum there would have two advantages. It would narrow the widely deplored gap between scientists and arts men, and it would defer the moment in a child's life when he has to choose between science and other subjects.

Prof. Mott then went on to discuss ways in which the universities could help the schools to widen the sixth form education with these ends in view. One way is to provide a means of entry into science faculties for those who have not specialized or have specialized late. Such opportunities already exist in the form of the Intermediate course, but Prof. Mott sees the possibility of an ambitious university, in co-operation with the Ministry of Education, founding a strong Intermediate course as the basis of a four-year course of study. He said he would like to see an increased emphasis on the 'General Paper' in scholarship examinations, and a renewed assurance given to the schools that this paper would be given a big role in awarding scholarships at Oxford and Cambridge. Another possibility is that a group of colleges would give an assurance that they would offer each year a certain number of mixed scholarships in which a candidate would take both arts and science subjects. Such scholarships do exist at Cambridge, but few candidates of high quality enter for them; nor, he thought, would the schools attempt this kind of education, unless they knew that scholarships would be reserved for candidates of this kind.

Another possibility might be that a group of colleges could set a qualifying examination, say one year before the entrance scholarship examination, in an arts subject. It would not be compulsory, but candidates who passed it would have a certain percentage of scholarships reserved for them. They would take the same papers in science as the specialists, but would not be in competition with them.

Prof. Mott felt that the right solution could best be obtained by a given university or college working in co-operation with a group of schools, rather than by experiments on a national scale.

Prof. F. A. Vick, head of the Department of Physics of the University College of North Staffordshire, agreed with Sir Philip Morris that courses in physics can be designed which contain everything that a complete education should have, and he went further than Sir Philip in believing that they should be so designed. He believes that they should teach a good fundamental knowledge of the subject and at the same time develop insight and imagination—as important in the physical sciences as in any other creative activity of the human mind—intellectual courage and honesty, understanding of scientific proof, ability to assess a situation, logical thought, clarity and precision of expression, experimental skill, ability to handle abstract ideas, judgment, recognition of the limitations of science, and humility in face of the wonders and mysteries of Nature.

An interesting suggestion brought out in Prof. Vick's paper was that he would advocate founding in some university a school which would stand alongside the Oxford 'Greats' and 'Modern Greats', and which would contain physics as a major component. Philosophy, physics and economics might be combined in such a course—P. P*. E. he called it. As a firm believer in the educational value of physics, he thinks that such a course would admirably equip the politicians, Civil servants and industrialists of the modern world. Prof. Vick's experience in teaching physics to arts students in courses lasting one or two sessions at the University College of North Staffordshire has convinced him that some of them become very interested in the subject, and are prepared to work hard in it, even if they would not wish to become professional physicists, and that they would be capable of doing well in a P. P*. E. combination. Even with the comparatively short courses at subsidiary level, the potential barrier which so often exists between an arts man and any science is penetrated or broken down. The whole outlook of the student is broadened.

Dr. A. W. Barton, headmaster of the City of London School, maintained in agreement with the other speakers that the school is just as important as the university; in particular, it has to choose the future scientists. He told how this is done at the City of London School. In the last resort, the choice is made by the boy and his parents; but Dr. Barton was emphatic that, in view of the needs of the community, the school would be right to lay strongly before a boy the advantages of a scientific career.

Dr. Barton does not think that the average physicist specializes too much at school. In the first four years he will spend two-thirds of his time on the humanities, and in the last three years one-third or one-quarter; and he does not think that Prof. Mott's "one period each of scripture, English, gym. and civics" is typical. Moreover, he believes that the sixth-form education is more liberal than it was forty years ago. Neither does he think that the competitive nature of the Oxford and Cambridge entrance scholarship leads to excessive specialization. The questions now set test no more ground than they did thirty-nine years ago. He thinks that the potential scholar is quite capable of answering these papers without being unduly pressed and without spending more than a reasonable time on science. It may well be that some pupils are over-specializing in the attempt to reach the standard of these papers; but that is not the fault of the papers, but of the schools in trying to prepare unsuitable pupils for them, and will soon disappear now as local authorities give reasonable assistance to potential physicists to go to the university even if they are well below the standard of an open scholarship.

---

# BRITISH SEISMOLOGY DURING 1954–55

THE sixtieth annual report of the Committee for Seismological Investigations appointed by the British Association, covering the work done by British seismologists during the year 1954–55, was presented to Section A (Physics and Mathematics) of the Association at its recent Bristol meeting. As part of the work carried out in the Department of Geodesy and Geophysics at Cambridge, Dr. M. N. Hill has continued his seismic refraction-shooting experiments in the English Channel and the Western Approaches. From the results obtained at a line of stations extending down the middle of the English Channel from the Greenwich meridian to the longitude of Weymouth, it was found that the depth to the palæozoic floor varied between 2,400 and 3,500 ft. These figures are smaller than had been expected by Dr. Hill. Dr. R. Stoneley has investigated the problem of the propagation of surface waves in a medium with cubic symmetry, the free surface of which is a principal plane. The propagation of waves of Rayleigh type is not possible for all values of the density and the three elastic constants; but when it is possible, the wave velocity depends on the direction of propagation. For the symmetrical cases of transmission along a principal axis, or along a bisector of two perpendicular principal axes in the free surface, Rayleigh wave-motion can occur, in which the particles describe ellipses in a retrograde direction. In these cases only can transverse motion (as in Love waves) exist by itself. In the general case the plane of the particles is inclined to the plane of propagation; in fact, the separation in an isotropic solid into Rayleigh waves and transverse motion occurs as a mathematically degenerate case of this general type of motion.

At the University of Durham Observatory, the building of an underground chamber for the seismographs has begun, and it is estimated that, when completed, the diurnal temperature variation in it will not exceed 1 deg. F. The director, Mr. E. F. Baxter, hopes shortly to be in possession of a Wilson–Lamison vertical seismometer to complete a set of instruments, the Observatory being equipped at present with two horizontal Milne–Shaw seismographs. The two earth tremors felt at Hemsworth and South Elmsall in south Yorkshire on October 23, 1954 (see *Nature*, 175, 587; 1955), have also been investigated by Mr. Baxter. The first was recorded at Durham, at Kew and at Rathfarnham near Dublin, though not at Edinburgh. From an analysis of the seismograms, Mr. Baxter has determined the epicentre at lat. 53° 36′ N., long. 01° 19′ W., and time of origin 13h. 26m. 10s. G.M.T. The strength of the shock macroseismically was III on the Modified Mercalli scale.

At the National Institute of Oceanography, Mr. J. Darbyshire has calculated refraction diagrams for microseismic waves approaching Bermuda on the assumption that they are surface waves between the ocean and the sea-bed of the type described by Stoneley. The diagrams show that the refraction of energy away from the island is very marked for waves approaching from the north-east and south-west. This effect explains some of the anomalies observed at Bermuda, in one of which a storm slightly to the west of north gave large microseisms, whereas one slightly to the east of north had little effect. The work shows that the study of recordings at islands must take account of refraction.

International co-operation is most important in seismology as in other sciences and, apart from private research and personal contacts, British seismologists have been recently active with the loan of instruments (a new driving clock has been ordered for the instrument at Suva, Fiji, with money from the Gray–Milne Fund), through the International Seismological Summary, and through attendance at the tenth General Assembly of the International Union of Geodesy and Geophysics in Rome during September 14–25, 1954. The International Seismological Summary is under the direction of Sir Harold Jeffreys, the calculations being done at Kew by Mr. J. S. Hughes and his staff. The work for June 1947 is in hand, the first five months of the year being ready for printing. The third quarter for 1946 will be distributed shortly. Dr. Stoneley reports that the programme of the General Assembly of the International Union of Geodesy and Geophysics was a very full one and was notable for the number of interesting and successful symposia and joint meetings of associations. For the first time since the Second World War, Soviet geophysicists were present, attending by invitation; in particular, the names of Prof. Vladimir Beloussov, of the Moscow Academy of Sciences, and Prof. Georgy Gorshkov, of the Moscow State University, may be mentioned. The Assembly was preceded by a reunion of the European Seismological Commission, under the presidency of Prof. W. Hiller. The proceedings of the Association of Seismology and the Physics of the Earth's Interior opened with a presidential address by Prof. B. Gutenberg on "The Effects of Low-Velocity Layers", and some of the joint meetings held were as follows: constitution of the Earth and dissipation of energy (with vulcanology); isostasy (with geodesy), and gravimetric and seismic interpretation: variation of latitude (with geodesy and vulcanology). In addition to special sessions on apparatus, on microseisms and on seismography, the grouping of papers under headings gave the meetings more of the character of symposia. The considerable development of seismology during recent years was evident.

ERNEST TILLOTSON

# ADVANCES IN MOLECULAR SPECTROSCOPY

## MEETING IN OXFORD

THE European Molecular Spectroscopy Group, which was constituted informally after the Second World War and held meetings in Constance (1947), Basle (1951) and Paris (1953), met again this year, in Oxford, during July 7–11. This meeting was a great success, and thanks are due to the industrial firms whose financial help made it possible. Among two hundred and eighty participants were representatives from fourteen European countries, Brazil, the United States, Canada, South Africa and Japan. More than eighty papers were presented, covering many topics in ultra-violet, infra-red and Raman spectroscopy, with an emphasis on spectral theory and the correlation of spectra with molecular constitution and reactivity rather than on technique or analytical applications.

The ease with which spectra can now be photographed or recorded automatically has stimulated more attention to different conditions of excitation and to the physico-chemical factors which determine detailed spectral characteristics. For example, very interesting results are emerging from the study of infra-red absorption spectra of gaseous mixtures at high pressure, or of mixtures of liquids. B. Vodar (Bellevue, Paris) and his colleagues, using mixtures of hydrogen chloride and hydrogen at high pressure, have found an infra-red absorption band corresponding to $(\nu_{HCl} + \nu_{H_2})$, the combination of the active hydrogen chloride fundamental with the inactive vibration of hydrogen. Also, the absorption band due to $\nu_{H}$, which becomes active at high pressures, is affected by hydrogen chloride or other added gases. Similarly, J. Fahrenfort (University of Amsterdam) has found that using compressed mixtures of carbon dioxide with nitrogen, oxygen or hydrogen, absorption bands are observed due to simultaneous transitions in a collision pair, such as $(\nu_{CO_2} + \nu_{N_2})$ or $(\nu_{CO_2} + \nu_{H_2})$; he has examined this effect in terms of the mutual molecular polarization and has found satisfactory agreement between the predicted and observed band intensities. All these measurements bear on the question of the formation of transient molecular complexes or aggregates, quite apart from the general information they may provide about intermolecular forces.

Analogous effects have been found for liquid mixtures by J. Ketelaar (University of Amsterdam). In thick layers, a carbon disulphide–bromine mixture shows bands at 1,807 cm.$^{-1}$ and 1,204 cm.$^{-1}$, lying respectively 306 cm.$^{-1}$ on either side of the strong absorption band of carbon disulphide at 1,510 cm.$^{-1}$. This displacement interval corresponds to the vibration frequency of bromine. When polyatomic molecules are mixed with carbon disulphide, an array of displaced bands is found, analogous to a vibrational Raman spectrum spread around the main carbon disulphide band at 1,510 cm.$^{-1}$. Thus we may not only detect collision complexes but also determine the low frequencies of a heavy molecule in a more convenient spectral region. H. L. Welsh (University of Toronto) described further work on the 'forbidden' infra-red bands of carbon dioxide and hydrogen in the liquid and solid states. At low temperatures these bands assume a more complex pattern in consequence of intermolecular interactions and specific properties of the crystalline solids, and combination transitions of hydrogen–deuterium molecular complexes have also been observed.

The interpretation of vibrational band intensities, which are as significant as the frequencies, has progressed rapidly. These intensities are controlled by the polar characteristics of the vibrations concerned, and therefore lead to deductions about bond polar properties and the electronic structure of the whole molecule. Since, moreover, the creation during molecular vibration of centres of residual electrical charge may be a prelude to reactivity, the absorption band intensities may be correlated with the latter. True integrated absorption band intensities, as opposed to their 'apparent' values or the 'apparent' extinction coefficients, can now be determined with fair accuracy. Use of these data is limited, however, by uncertainties in the molecular force fields and by ambiguities which arise in part since the square root of the intensity has an indeterminate sign. One possible way out is to study a set of isotopic molecules where for a given vibration-type the derivative o electric moment with respect to a symmetry coordinate should be constant. B. L. Crawford (University of Minnesota) described such work on ethylene and the deutero-ethylenes, and on the methyl halides, D. F. Hornig (Brown University) on methyl cyanide and the cyanogen halides, and D. H. Whiffen (University of Birmingham) on benzene. It is noteworthy that in some of these structures, carbon–carbon bonds are found to have fairly large dipole moments.

S. Silverman (Johns Hopkins University) has determined the integrated band intensities of hydrogen halides and carbon monoxide from measurements on individual rotation lines, and has analysed the results in terms of a new more detailed theory which assumes a more general expression for the variation of dipole moment with bond-length and which also considers vibration–rotation interaction. Theoretical work on the band intensities of hydrogen halides was also discussed by S. Penner (California Institute of Technology, Pasadena).

The function expressing variation of a bond dipole with change in length, $M = M_0 + M_1\xi + M_2\xi^2 + \ldots$, has assumed greater interest since it is now realized that most vibrations involve considerable electrical anharmonicity, expressed by the quadratic and higher terms in $\xi$, and this determines the overtone intensities more than mechanical anharmonicity. H. W. Thompson and D. W. Russell (Physical Chemistry Laboratory, Oxford) described work on the bands $\nu_{NH}$ and $2\nu_{NH}$ of a selected series of complex organic molecules including aliphatic and aromatic secondary amines, amides and heterocyclic bases, from which the coefficients $M_1$, $M_2$ can be derived and correlated with variations of ionic character in the different kinds of NH bond.

Attempts have been made to correlate the variation of vibration frequency of a key group in a related series of molecules with changes in reactivity. L. J. Bellamy (Waltham Abbey) discussed further examples of substituted benzenes in which a relation exists between a particular vibration frequency and the Hammett σ-factor for the particular substituent. Such relations might be applied to estimate dissociation constants of acids and bases, redox potentials, etc., although there are some anomalies and the frequency variations are often small. Any inductive or mesomeric effects will be similarly reflected in the bond polar properties, and the consequential variation of band intensities may be more pronounced than the frequency shifts. Thus, H. W. Thompson showed that for the C≡N bond vibration in substituted benzonitriles there is a proportionality between log (intensity) and σ over a wide range, and similar correlations between the intensity and several reaction constants. A striking difference of intensity of $\nu_{OH}$ in the solvent carbon tetrachloride or chloroform was noticed in cases where hydrogen bonding of chloroform to the solute could occur favourably, which emphasizes the need for care where quantitative analysis is being carried out in apparently innocuous solvents. The intensities of NH-group vibration bands in platinum-amine complexes have also been correlated with electronic structure by L. A. Duncanson (Imperial Chemical Industries, Ltd., Welwyn); and G. Higgins (British Rubber Producers' Research Association, Welwyn) described how infra-red studies of the association equilibria between organic hydroperoxides, phenols or alcohols with dialkyl sulphoxides may be used to estimate the dissociation constants of weak acids.

Higher resolving-power in the infra-red, obtained with better detectors and gratings, is being used to obtain further details of molecular dynamics. Fermi resonance between vibrational levels often leads to anomalous values in the coefficients $\alpha_i$ relating the rotational constants in different vibrational states, and also in the centrifugal stretching-constants $D_i$. More accurate values can also be obtained for the Coriolis coupling factors $\zeta_i$ and $l$-doubling coefficients in degenerate vibrational levels. Such work on carbon dioxide, nitrous oxide and allene was described by H. H. Nielsen (Ohio State University), on some hydrides of the fourth-group elements by M. Kent Wilson (King's College, London), and on acetylene, methyl acetylene, hydrogen cyanide and their deuterium analogues by H. W. Thompson. A further revision of the bond-lengths in acetylene seems necessary. W. F. Edgell (Purdue University) explained a new method whereby the measurement of vibrational band contours promises to yield values for the molecular rotational constants.

Many papers were concerned with general infra-red developments and vibrational analysis. L. Genzel (University of Frankfurt) described a new grating spectrometer for use to 1,000μ, using a high-pressure mercury arc as source with suitable filters. R. C. Lord (Massachusetts Institute of Technology) and his colleagues have found from the spectra of *cyclo*butane and *cyclo*propane and of their deutero analogues that the former appears to contain a puckered ring, and in the latter $r_{cc} = 1524$ A. R. Mecke (University of Freiburg) has measured the spectra of homologous series of αω-dibromoparaffins and alkyl bromides in the liquid and solid phases. In the solids, rotational isomerism is excluded, and by considering the whole series a reasonable assignment of the carbon-chain vibrations can be made. S. F. D. Orr (Chester Beatty Research Institute, London) has found that in *trans* stilbenes, although the integrated intensity of the nonplanar =C—H deformation is unaffected by *ortho* substituents, the band-width and peak extinction coefficients are much affected, and an explanation in terms of vibrational damping is suggested. N. Sheppard (Laboratory of Colloid Science, Cambridge) has assigned the vibration frequencies of the guanidinium ion, $C(NH_2)^+_3$, in crystals and solid films, and data relevant to the study of ureas and amides. Mlle. M. L. Josien

(University of Bordeaux) and colleagues have measured $\nu_{CO}$ in ketones and in quinones of mono- and poly-nuclear aromatics, while N. Fuson (Fisk University) has studied substituted benzanthracenes of carcinogenic interest. The assignment of OH-group vibrations in enolized diketones and ketonic alcohols has been explored by D. Hadzi (University of Ljubljana) and by C. Duculot (University of Paris), and W. Lüttke (University of Freiburg) has studied the dimerization of nitroso compounds.

A packed session of the meeting, on the infra-red spectra of amides, peptides and polymers, served to emphasize the difficult stage which this work has reached, and the hazards of interpreting spectra with polarized radiation. G. B. B. M. Sutherland (University of Michigan) suggested that analysis in terms of group frequencies can only provide a partial interpretation. With crystalline polymers, in which a structural unit is visualized in the unit cell, appropriately influenced by its environment, more exact selection rules will apply than with liquid or amorphous polymers. He illustrated this argument by reference to polyethylene, ice and other substances. From results with crystals of naphthalene, iodoform and thiourea, R. M. Hexter (Cornell University) claimed to verify a point made several years ago, but not sufficiently appreciated, that transition moments of vibrations are often not parallel or perpendicular to bond directions; and he suggested that if dichroic ratios are to be correctly determined the complete anisotropy must be measured. A. Elliott (Courtaulds, Ltd.) has found that with crystals of acetanilide the transition moment of the carbonyl group is inclined to the bond direction.

E. K. Blout (Polaroid Corporation) observed that, whereas lower members of a series of polybenzyl glutamates have $\nu_{CO} = 1,628$ cm.$^{-1}$, the higher members have $\nu_{CO} = 1,655$ cm.$^{-1}$, in line with β- and α-configurations of polypeptides; and he suggested that some previous discrepancies between different laboratories might arise from degradation of polymers during the casting of films from solvents. H. A. Willis and R. G. J. Miller (Plastics Division, Imperial Chemical Industries, Ltd.) proposed a method for determining the crystalline–amorphous content of polymers such as polyethylene or polyethylene terephthalate, based only upon the broad bands of the amorphous form which are associated with the multiplicity of rotational isomers; J. Mann and J. Marrinan (British Rayon Research Association) showed how the hydroxyl group bands in different crystalline forms of cellulose can be used to characterize the latter; the old problem of the 'amide group' bands in the gaseous, liquid and crystalline state was reconsidered by S. Mizushima (University of Tokyo) and by M. Davies (Aberystwyth); and D. S. Barmby (Wool Industries Research Association, Leeds) outlined the effect on key bands of nylon when it is dissolved in antimony trichloride—a possible start to the study of the swelling of polymers.

As regards theoretical aspects, C. A. Coulson (Mathematical Institute, Oxford) showed how data on the lengths of carbon–carbon bonds can now be systematized in terms of specific types of hybridization and hyperconjugation. J. W. Linnett (Inorganic Chemistry Laboratory, Oxford), in reviewing possible ways of assessing molecular force fields, suggested that more use might be made of isotopic effects other than with hydrogen–deuterium, and that the Coriolis factors $\zeta_i$ and centrifugal stretching constants $D^i$ mentioned previously may also be useful. New methods were outlined by P. W. Higgs (Mathematical Physics Department, Edinburgh) for calculating the vibration frequencies of complex molecules, and by H. Günthard (Federal Technical Institute, Zurich) for obtaining relations between the intensities of bands of isotopic molecules, while G. Amat (P.C.B., Paris) considered the effects of Fermi resonance upon molecular rotational and vibrational energy-levels in detail. P. Tuomikowski (University of Helsinki) described comparative studies of Fermi resonance for a given molecule in different states of aggregation.

Raman spectra of coloured substances, using red or near infra-red radiation as the exciting source, were described by H. Stammreich (University of São Paulo); discharge lamps of helium, rubidium or cæsium were used, and the substances studied included bromine, iodine chloride, iodoform and polyhalide ions. Raman spectroscopy of gases with high resolution, using multi-reflexion cells and high-current water-cooled mercury arcs, is advancing rapidly, and H. L. Welsh (University of Toronto) gave new data on vibration-rotation bands of a number of simple hydrocarbons. This method not only provides information about certain bands not obtainable in the infra-red, but also the confusing influence of 'hot' bands is sometimes minimized. Several speakers discussed Raman spectra of crystals and complex ions, and on the basis of intensities of Raman bands in homologous series of ketones, esters and nitro compounds G. Michel (University of Liège) suggested that rules can be set up for analysis and structural diagnosis. D. A. Long (Physical Chemistry Laboratory, Oxford) discussed the more fundamental relationships between Raman band intensities and bond polarizabilities, with special reference to tetrahalides and related structures. Progress here runs parallel to that already mentioned in which infra-red band intensities are being correlated with bond polar properties.

W. C. Price (King's College, London), B. Vodar (Bellevue, Paris) and A. D. Walsh (University of Leeds) discussed technical advances in the vacuum ultra-violet and the correlation of absorption spectra with molecular ionization potentials. Improved emission sources and continuous photoelectric recording should lead to further progress in this field. H. Schüler (Hechingen) has obtained evidence for the ultra-violet emission spectra of benzyl and benzal radicals produced in the positive column of a glow discharge in vapours of certain benzene derivatives—an experimental method which may provide many data on the emission spectra of polyatomic molecules. The absorption spectra of such radicals have also been measured by G. Porter (British Rayon Research Association) after 'trapping' radicals formed by flash photolysis in a rigid medium where they persist for long periods in metastable equilibrium. This trick of retaining simple polyatomic radicals in solid matrices was also described by G. Pimentel (University of California). The use of crystals of aromatic compounds at very low temperatures has also enabled P. Pesteil (Sorbonne, Paris) to obtain sharper fluorescence spectra ($T \rightarrow S$) and to determine many molecular vibrational levels. Other ultra-violet studies included the exciton spectra in inorganic crystals at low temperature (S. Nikitine, University of Strasbourg); the effect of substituents on the spectra of diphenyls and benzophenones (G. H. Beaven, National Institute for Medical Research, Mill Hill, and R. F. Rekker, Free University of Amsterdam); the spectra of benziminazoles and thiophenes; and many new spectra of diatomic oxides, halides and diatomic ions which extend general theories of molecular structures further. H. C. Longuet-Higgins (Chemistry Laboratory, Cambridge) analysed theoretically the electron states of a composite system in relation to those of its constituent parts and showed how some general ideas about electron transfer configurations can be used in this connexion. R. S. Mulliken (University of Chicago) and C. J. Timmons (University of Nottingham) discussed charge transfer and charge resonance spectra and the correlation of spectra with intermolecular complex formation.

H. W. THOMPSON

# PROGRESS IN RADIOBIOLOGY

## CONFERENCE AT CAMBRIDGE

ON August 15, radiobiologists met in Cambridge for the third annual conference to discuss progress in their field. The three-day meeting, under the chairmanship of Sir Ernest Rock-Carling, was organized by Prof. J. S. Mitchell and his staff. Some 250 scientists, from sixteen countries including the U.S.S.R., enjoyed the hospitality of our Cambridge hosts. Eighty papers were discussed, the variety of the contributions reflecting the large number of disciplines on which an understanding of the biological effects of radiation must rest.

Biological lesions due to ionizing radiations must originate in the process of absorption of primary energy. Our current picture of the particle track, and relevant knowledge of the nature of the chemical intermediates, were presented by Prof. F. S. Dainton in an introductory lecture. A number of metabolic steps occur between the initial chemical disturbance and the appearance of damage in the organism, and some papers dealt with such effects. In the bacterium *Achromobacter fischeri*, the enzymatically controlled luminescence decreases during exposure to X-rays and recovers rapidly afterwards. Both decrease and increase follow an exponential time relationship (O. Hug and I. Wolf). Bacterial enzymes show a lower sensitivity to X-rays at low temperatures when exposed in the dry state or in solution, or when in the intact cell, suggesting some common physicochemical mechanism of inactivation (H. Pauly and B. Rajewsky). It appears, however, that in the etiology of the opacity of rabbit lens caused by X-rays, biochemical changes in the lens are secondary to cellular damage in the dividing cells of the lens epithelium (A. Pirie).

The genetic effects of radiation took a prominent place in the discussions. Nucleic acids appear to be the main carriers of hereditary factors, and some insight into the action of radiations on genetic material may be expected from the study of radiation effects on them and their metabolism. Some questions discussed were the effect of ultra-violet light on ribonucleic acid metabolism in starfish oocytes (M. Errera and A. Ficq), the inhibition of deoxyribonucleic acid (DNA) synthesis by X-rays in the early stages of regeneration of rat liver (L. K. Mee), and the interesting results obtained in the irradiation of dry preparations of herring sperm deoxyribonucleic acid (P. A. Alexander and K. A. Stacey). The sensitivity of female germ cells of mice to the induction by X-rays of dominant lethal mutations is some seventy times greater at first meiotic metaphase than at a stage seven hours earlier (L. B. Russell and W. L. Russell). In *Habrobracon* eggs irradiated with ultra-violet light, damage to the nucleus is qualitatively and quantitatively different from cytoplasmic damage (R. C. von Borstel and H. Moser). A surprising result was obtained when a breeding population of *Drosophila* was exposed to 5·1 r. per hr. for about five years. Its genetic fitness was only 1–5 per cent lower than that of an unirradiated population, despite an accumulated dose of 250,000 r. (B. Wallace). We are not justified, however, in extrapolating from insects to mammals on the basis of these data (W. L. Russell). Bacteria and bacteriophage have been used as a simplified model for the study of genetic changes in populations (H. Marcovitch).

Since certain chemicals and X-rays cause similar biological damage, it is of interest to study the mechanisms by which these lesions arise. A whole-body dose of 100 r. of X-rays, or 1 mgm. per kgm. of nitrogen mustard, produce the same damage in rat lymph nodes; but the treatments have dissimilar actions since they are not interchangeable (C. Biagini). N,N-dichlorethyl-*p*-amino-phenyl-butyric acid causes mainly lymphoid, whereas 'Myleran' causes mainly myeloid effects in rat bone marrow. The effect of X-rays can be reproduced almost exactly by applying both chemicals at once, suggesting two separate physiological pathways for the developing X-ray damage (L. A. Elson, D. A. G. Galton, L. F. Lamerton and M. Till).

Factors influencing the radiosensitivity of biological systems were discussed in almost every session. It has been known for some time that radiation effects are usually greater in the presence than in the absence of free oxygen. Tails of young mice were used to demonstrate this with X- and neutron-irradiation (P. Howard-Flanders; E. A. Wright). The rapid autoxidation of cysteine in aqueous solutions suggests that a number of protective effects ascribed to this compound could be accounted for by anoxia (L. H. Gray). Cysteine and cysteamine have a stimulating effect on the oxygen consumption of liver slices. Their protective effect may therefore be due to a reduction in the amount of free oxygen in some organs (D. W. van Bekkum). Chemical protection and anoxia do not, however, always seem to act along identical pathways (R. W. Brauer, J. S. Krebs and R. Pessotti; J. Maisin, P. Maldagne, A. Dunjic and H. Maisin). Further, cysteine and cysteamine react with the sulphhydryl group of proteins and might thus protect the protein (L. Eldjarn and A. Pihl; R. Koch).

The effects of oxygen on radiosensitivity may be explained in terms of the relative efficiencies of oxidizing and reducing radicals in reacting with organic molecules, although the state of oxidation of the acceptor substances is of importance (A. J. Swallow; M. Ebert and A. Howard; H. Laser).

The radiosensitivity of barley seeds and of starch depends on humidity, and is at a minimum at 20 per cent. It was suggested that the cause is physicochemical rather than physiological (L. Ehrenberg). The production of chromosome aberrations in *Vicia faba* roots by 8-ethoxycaffeine or X-rays is sensitive to oxygen, but adenosine triphosphate appears to be involved only in the case of the caffeine (B. A. Kihlman). Other work on *Vicia* indicates that inhibition of oxidative phosphorylation interferes with the rejoining of broken chromosomes (S. Wolff).

It is well established that shielding of hæmopoietic tissue, or implantation of such tissue after irradiation, greatly improves the recovery of animals from acute radiation injury. It seems likely that the implanted cells are fully effective only if not destroyed by tissue antibodies (D. M. H. Barnes and J. F. Loutit). Spleen irradiated *in vitro* or taken from an irradiated donor can resume hæmopoiesis in the host even after a dose of 10,000 r. (E. H. Betz, G. Booz and J. Firket), and the spleen of an irradiated animal recovers more quickly if part of its bone marrow is shielded (E. H. Belcher, E. B. Harris and L. F. Lamerton).

The carcinogenic effect of a given dose of whole-body X-irradiation is approximately the same whether given in daily, weekly or fortnightly fractions, but is less effective when delivered in one exposure, as judged by the appearance of leukæmia in mice (R. H. Mole). Beta-radiation applied to the skin of rats produces more tumours when given in two exposures than in one (J. W. Boag and A. Glücksmann). Glass beads containing strontium-90 produce tumours at the site of implantation under the skin of rats, and the incidence of tumours is proportional to the logarithm of the radioactivity (G. Schubert, H. A. Künkel and G. Uhlmann). Rats of a tumour-free strain, protected by cysteamine or part-shielding against the acute effects of X-irradiation, develop a variety of tumours if they survive more than six months (Maisin *et al.*). Therapeutic irradiation for ankylosing spondylitis appears to be followed by a five- to ten-fold increase in the rate of deaths from leukæmia (W. M. Court-Brown).

For those who attended the previous conferences (Aarhus, 1953, Liège, 1954), several points of increased emphasis became apparent at this meeting. They included more widely based inquiries into the mechanism of action of protective agents, the long-term carcinogenic effects of radiation, and the search for biochemical links in the developing radiation-induced lesion.

A. Howard

# NEW NATURE RESERVES IN GREAT BRITAIN

The Nature Conservancy has announced the establishment of five new nature reserves, three in England and two in Scotland, as follows: Roudsea Wood, Lancashire (ten miles west of Grange-over-Sands); Wybunbury Moss, Cheshire (three and a half miles south of Crewe); North Fen, Lancashire (two miles west of Windermere); Hermaness, Unst, Shetland; and Noss, Shetland. The Conservancy has also announced the addition of areas to the following two existing reserves: Castor Hanglands, Northants (four and a half miles north-west of Peterborough); and Kingley Vale, Sussex (four miles north-west of Chichester).

Roudsea Wood is one of the most varied woodlands in the British Isles, with a rich flora and fauna and many different types of vegetation. It lies in the south of the Lake District and is the first nature reserve to be declared within an English national park. The reserve, which has been formed by agreement with the owner, Mr. R. E. O. Cavendish, covers an area of 287 acres and is about ten miles west of the Conservancy's Research Station at Merlewood, Grange-over-Sands, Lancashire. The main part of the wood consists of two parallel ridges, one of limestone and one of slate. The limestone ridge is crowned by a yew wood and has interesting mixtures of oak and ash on its flanks with a luxuriant ground flora, including lilies-of-the-valley. The slate ridge, on the other hand, is a typical Lake District slate oak-wood which has, in part, been coppiced for charcoal production. Between ridges there is a small tarn, now nearly filled, and around it an abundance of fen plants and fen insects. Among these is a sedge (*Carex flava*) for which this is the only British locality. There are a wealth of sloe, alder, birch and other shrubs, and a correspondingly great variety of insect and bird life.

On its seaward side, Roudsea Wood slopes down into the Morecambe Bay salt-marshes, this being one of the few places where the transition from salt-marsh to woodland can be studied. On the landward side lie the Holker mosses, and the transition from the vegetation of peat to that of limestone and slate is also of very great biological interest. In addition to the usual plants and insects, there are roe-deer, occasional fallow and red deer, and a great variety of wild-life of every kind. One of the main objects of this reserve is to serve as an undisturbed outdoor laboratory for the scientific workers at Merlewood, who have already begun their investigations, and applications for permits to visit the reserve for research or collecting purposes should be made to the Conservancy's regional officer at Merlewood.

Wybunbury Moss in South Cheshire is an unusually large example of a 'Schwingmoor', a type of bog not before described in Britain. It has been formed in a steep-sided kettle-hole in sandy, glacial material, the sides of which are cultivated and used for grazing. Only part of the land has been declared a reserve, and it is hoped to extend the area in the future. At the centre of the bog there is only a thin crust of sphagnum peat 6–10 ft. deep floating on water, but at the margin deposits of both sphagnum and fen peat have accumulated to form a solid organic layer over the glacial sand. The surface vegetation shows a surprising variety for such a small area. The margins, which must receive a mineral supply from the cultivated sides of the kettle-hole, carry a fen community with sedges such as *Carex paniculata*, but this fen is a secondary development because it is underlain everywhere by sphagnum peat. As a marked contrast, the central area shows a typical bog flora carpeted with sphagnum species in which cross-leaved heath (*Erica tetralix*), cranberry (*Oxycoccus palustris*) and marsh andromeda (*Andromeda polifolia*) are common. The ground is gradually becoming drier as part of the natural development, and, as this occurs, trees, mainly birch and scots pine, are spreading. The reserve will be used solely for scientific research, and permission to visit it can only be obtained through the Conservancy's officer at Merlewood.

The main interest of North Fen is that it shows the vegetational succession characteristic of the climatic conditions found in north-western England—open water, rich in mineral salts, to fen-carr and bog. It is mainly woodland and is only just beginning to show signs of sphagnum bog development, in contrast to the nearby Blelham Bog reserve, where there is very little left of the original woodland. The reserve lies on the north side of Esthwaite Water in the Lake District National Park and is being established under a lease from the National Trust. The vegetational succession in North Fen is reedswamp (*Phragmites communis* dominant, with *Scirpus lacustris* on the offshore margin), mixed fen (predominantly a sedge association with *Carex elata* and *Carex rostrata* conspicuous), open carr followed by closed carr (dominated by *Salix atrocinerea*). Some modification of this succession occurs, particularly on the western and eastern flanks of the fen as the result of a difference in the rate of inorganic silting. It appears that, in north-west England, fen communities are only developed where substantial inorganic sedimentation occurs. Such communities are of a purely transitional nature, eventually giving way to bog as the organic/inorganic ratio of the substrate increases. Access to the reserve will not be restricted, but to collect specimens permission is needed from the Conservancy's officer at Merlewood.

Muckle Flugga and the Outstack, the northernmost of all the British Isles, are included in the new nature reserve of Hermaness, which is closer to the north pole than the southern tip of Greenland. Hermaness itself is a peninsula on the north-west of the Island of Unst, Shetland, and carries rough moorland with blanket bog on gneiss; there are many lochans and several miles of high sea-cliffs. The size of the reserve is 1,071 acres, all but 31 being on the mainland. The scientific interest of the reserve is mainly ornithological, in particular as an important breeding-station of the great skua, a bird with a very restricted distribution in the northern hemisphere but also breeding in the Antarctic. An ancestor of the present proprietor, Lieut.-Colonel Laurence Edmonston, was responsible for protecting the great skuas on Hermaness: in 1850 there were only two pairs; by 1890 there were not more than nine pairs; later the increase there and elsewhere was rapid; and to-day there are about five hundred pairs nesting on the reserve. In addition, the species has spread to other parts of Shetland and to the Orkney Isles. Besides great skuas, numbers of arctic skuas, red-throated divers, eider duck and arctic terns breed on the peninsula. The sea-cliffs contain an expanding gannetry and also colonies of guillemots, razorbills, kittiwakes, puffins, storm petrels and other birds. There is a watcher's hut on the slopes of Hermaness Hill. The Royal Society for the Protection of Birds will continue to provide a warden, as before.

With its great cliffs, Noss is one of the most spectacular islands in Europe. Divided from the mainland of Shetland by the larger island of Bressay, Noss Head rises to 592 ft., and the uninhabited island extends to 774 acres, mainly of rough moorland. On the cliffs there are many nesting gannets, guillemots, shags, kittiwakes, puffins, greater black-headed gulls and herring gulls. On the moorland there are colonies of great and arctic skuas, and the eider duck also breeds there. Geologically, Noss exhibits striking erosion in sandstone and phyllites of the Old Red Sandstone age. The Royal Society for the Protection of Birds will continue to provide a warden, as before.

The Castor Hanglands nature reserve was declared by the Nature Conservancy in June last year, and the present declaration completes the reserve by bringing in an area of 113 acres, under a lease from the Forestry Commission—the western portion of Castor Hanglands Wood which adjoins Ailsworth Heath. The woodland fringe now added completes a series of habitat types characteristic of this part of the Midlands, few examples of which still remain. The grass heath, which is not represented on the other Nene reserves, merges into the fringing shrub margin of the oak–ash woodland. The whole area has long been known for its rich insect life and particularly for butterflies, such as the black hairstreak and the chequered skipper. There are two small pools which support a variety of aquatic vegetation. Access to this area and the Blacklands part of the reserve is by permit only, obtainable from the Conservancy's regional officer for East Anglia at 6 Upper King Street, Norwich.

The latest addition of a further 17½ acres to Kingley Vale completes this reserve of approximately two hundred acres which was first declared in 1952. The reserve includes a famous natural yew wood, chalk grassland on the downland slopes, and an area of heath overgrown by scrub on the plateau of Bow Hill. The additional area is a well-developed heath on the clay soil of the plateau and provides a marked contrast to the grassland of the chalk slopes. The predominant plants are heather and other species typical of acid soils, but there are also some chalk grassland species which have deep roots penetrating to the underlying chalky soil. Thus the area is of particular value for studying the distribution of species which are restricted to either calcareous or to acid soils. As with the rest of the reserve, there are no restrictions of access, but permission is required to collect specimens, application for which should be made to the Conservancy's regional officer for the south at Furzebrook Research Station, Wareham, Dorset.

# THE MEDICAL RESEARCH COUNCIL

## REPORT FOR 1953–54

THE report for 1953–54 of the Medical Research Council (pp. v+274. Cmd. 9506. H.M.S.O. 7*s.* 6*d.* net) follows the plan used during recent years. The work of the Council's many establishments is given only in summary, together with a list of the scientific papers published by the Council's many workers, from which the reader may learn the extraordinarily wide range of the Council's activities; but the main part of the report discusses each year, from a broader point of view, some aspect of the general trends of medical research.

This year the report considers, in a fascinating article entitled "Modern Trends in Chemotherapy", the remarkable researches which are gradually transforming our methods of treatment of many serious diseases. Not the least interesting part of this article is its introductory account of the evolution of modern methods of research in this field and the development of the co-operation between biologists and biochemists which has enabled us either to attack directly biochemical processes upon which the lives and activities of pathogenic organisms depend or, in some instances, to reinforce the defensive mechanisms of the host, so that the host is enabled to deal more effectively with the pathogenic organism that invades its body. This phase of chemotherapeutic research began with the discovery by Dr. D. D. Woods that sulphanilamide derivatives exercise their antibacterial effects by interfering with a metabolite essential to the pathogenic organisms concerned, namely, *p*-aminobenzoic acid, the chemical constitution of which closely resembles that of sulphanilamide. Sir Paul Fildes then supplied the hypothesis that an effective chemotherapeutic agent will be a substance that interferes with some essential metabolic reaction of the pathogenic organism, and that such a substance should be sought among compounds biochemically similar to those normally utilized by the pathogen. This Woods–Fildes theory is a special application of the results of earlier work by Prof. J. H. Quastel and

Dr. Marjorie Stephenson, which showed that enzymic reactions are inhibited by compounds chemically similar to those in which the enzymes normally produce a change. This is a good example of the way in which academic research may lead to ideas of practical importance and of the valuable results that may result from the policy consistently followed by the Medical Research Council of fostering fundamental researches of a kind that may form the bases of advances in practical methods of actually treating disease.

For details of the remarkable biochemical work now being done by the Council's workers, the article just mentioned must be consulted. It deals with work on factors which influence radiosensitivity, the action of biologically active substances on tissue cultures, blindness in premature infants, pernicious anæmia, cortisone in the treatment of ulcerative colitis, trends in research in human malnutrition, the neurotic in industry, pneumoconiosis, analgesia in midwifery and research on the mechanism of virus infection. The reader in search of dramatic developments will certainly find them here. Dramatic undoubtedly are the results achieved by the staff of the Strangeways Laboratory at Cambridge. Directed by Dr. Honor B. Fell, this Laboratory has been quietly developing for many years the tissue-culture technique as a tool which has widespread applications. The brief account given in this report of some of the results achieved shows what can be accomplished by this technique. Work on the effects of vitamin A on chick ectoderm growing in tissue cultures has, for example, not only confirmed that absence or deficiency of vitamin A results in keratinization, but also it has produced the remarkable result that high concentrations of vitamin A can convert growing ectoderm into ciliated epithelium secreting mucus that is indistinguishable from the normal epithelium of the respiratory tract of the chick. It seems, therefore, that one of the functions of vitamin A is to control the structure and function of certain epithelial cells, and the intact animal seems able to pick out of the circulating fluids the level of vitamin A needed for its normal development. Not less interesting is the tissue-culture work done on the effects of substances produced by the thyroid gland and by insulin.

Dramatic also is the work outlined in this report on the cause of blindness that developed in the United States and in Britain in premature infants. This proved to be a result of the action of oxygen treatment normally given to these infants. A result of this treatment apparently may be that, when a premature infant is exposed to high concentrations of oxygen for the periods of time formerly considered to be necessary, the blood vessels supplying the retina of the eye become constricted and eventually the blood supply to the retina becomes obliterated. When the infant is afterwards returned to normal air with less oxygen in it, the retina demands, so to speak, more oxygen, and an overgrowth of blood vessels occurs which is so exuberant that it results in filling the back of the eye with fibrous tissue in which the retina is involved, so that all power of sight is irretrievably lost. The remedy that has now been successfully applied is a drastic reduction of the oxygen treatment.

These two examples of the work recorded in this report will suffice to indicate the quality of the beneficent work that is being done by the Council. As the report itself implies, the discoveries which attract public attention and bring great relief of suffering to mankind are inevitably based on long months of patient and unspectacular labour performed by many workers who each contribute something essential to the final triumphs. All these workers, whatever their status, deserve our gratitude, as do, indeed, all those others who work outside the Council's authority but contribute no less in their several ways to the general and continuous progress of medical research.

G. LAPAGE

# UNIVERSITIES COUNCIL FOR ADULT EDUCATION

"ACHIEVEMENT under difficulty" is the dominant note in the report of the Universities Council for Adult Education for the year 1953–54 (Universities Council for Adult Education. Report on the year 1953–1954. Pp. 28. (Bristol: W. E. Salt, Hon. Secretary and Treasurer, 1955)). The timely financial assistance given by the Ministry of Education enabled extra-mural departments to carry on with their existing work and even to venture on a certain amount of exploratory work. While the total number of three-year tutorial classes fell, for the first time since the War, from the previous session's total of 1,001 to 974, the number of one-year sessional classes, which had fallen slightly in the previous session, rose by twenty-three to the record figure of 1,283. Six universities report increases in the number of three-year classes and no fewer than ten an increase in two types of longer courses. Moreover, London and Manchester achieved record numbers of three-year classes: the London total has been climbing steadily for some years and is now more than twice as large as before the War. The total number of students has increased with the number of classes.

A remarkable feature about the subjects of study is the rise of history to the leading place, with 684 classes out of the total of 3,994 as against 597 in the previous session and 584 in 1951–52. Most subjects show a substantial increase over the figures for the previous session, but only history, the sciences and the arts have yet recovered the ground lost since 1951–52. In the case of psychology, there has been a continued decline from 294 classes in 1950–51 to 184 in the present session. The number of courses in the physical and biological sciences increased by 56 during the year to a total of 434. Taken together, they stand fifth in the order of subjects, while the physical sciences alone stand higher than psychology, religion and government, and very little below philosophy.

A number of interesting courses and experiments was undertaken. Sheffield had large audiences for courses in "Twentieth Century Physics", "Electrons in Action", and various aspects of engineering; Bristol even larger audiences for "Seeing Atoms" and "The Living Brain"; while London was highest with the thousand who attended a course on "Atomic Energy". London held a rewarding residential course on "Embryology" for graduates in biology, and a similar 'refresher' course conducted by Birmingham, as one of an established series, had far-reaching results. The main problem in science was the provision of courses for non-scientists.

Interesting experiments have also been carried out in the supply of special courses for trade unionists.

# AMINO-ACID SEQUENCE OF ALPHA-CORTICOTROPIN

By PROF. CHOH HAO LI and DRS. IRVING I. GESCHWIND, R. DAVID COLE,
ILSE DOROTHEA RAACKE, J. IEUAN HARRIS and JONATHAN S. DIXON
Hormone Research Laboratory and Department of Biochemistry, University of California, Berkeley

THE isolation and partial structure of α-corticotropin, a polypeptide from sheep pituitary glands possessing adrenocorticotropic (ACTH) activity, have been reported from this laboratory[1-3]. In this preliminary communication, we wish to propose a complete amino-acid sequence, deduced from the structure of peptide fragments isolated from enzymatic and partial acid hydrolysates of the hormone.

## Action of Pepsin

Earlier investigations demonstrated that limited digestion with crystalline pepsin effects the cleavage of peptides and amino-acids chiefly from the C-terminal portion of the molecule. The core material remaining after peptic digestion, which may be separated from smaller peptide fragments by precipitation in 25 per cent trichloroacetic acid solution, was shown to possess ACTH activity.

150 mgm. of α-corticotropin trichloroacetate[1,2] and 2·4 mgm. of crystalline pepsin were dissolved in 45 ml. of 0·01 *M* hydrochloric acid and kept at 37° C. for four hours. After the whole digest had been heated to 100° C. for two minutes, it was mixed with an equal volume of 50 per cent aqueous trichloroacetic acid. After the solution had stood for one hour at 0° C., the precipitate was removed by centrifugation. The supernatant fluid was freed of excess trichloroacetic acid by repeated extractions with peroxide-free ether, and was then taken to dryness by lyophilization. The dried residue, weighing 22·5 mgm., was dissolved in 0·1 ml. of water. A small aliquot containing about 0·2 mgm. of the residue was applied to paper as a spot, and the remaining solution was applied as a band (0·5 × 5 cm.) close to the spot. The chromatogram was developed by the descending procedure in the *n*-BuOH/HOAc/$H_2O$ (4 : 1 : 5) system of Partridge[4]. After being dried, the 'spot' chromatogram, which was to serve as the guide strip, was cut out and sprayed with ninhydrin solution. The zones in the 'band' chromatogram corresponding to the spots on the guide strip (Fig. 1) were cut out and the material was eluted with 0·3 ml. of 5 per cent sodium bicarbonate. Each eluate was allowed to react with Sanger's reagent, fluorodinitrobenzene, in the manner described by Porter[5]; the reaction mixtures were acidified and fractionated by extraction first with ether and then with ethyl acetate. Both fractions were submitted to chromatography on paper with *tert*-AmOH/*iso*-AmOH/3 per cent $NH_3$ (2 : 1 : 3) as the developing solvent; each of the spots in these chromatograms was cut out and the material was eluted with 2 per cent ammonia. The hydrolysate of each eluate was analysed for N-terminal amino-acids by the chromatographic procedure of Levy[6], and for the remaining amino-acids by one-dimensional chromatography on paper in the solvent system *n*-BuOH/HOAc/$H_2O$ (4 : 1 : 5). The C-terminal amino-acids in some of these peptide fractions were investigated by the carboxypeptidase procedure[1]. The following peptides[7] were identified: asp.glu; asp(glu,ala); asp(glu,ala)ser; glu(ala,ser); ser.glu; ser(glu,ala); ser(glu,ala,phe); glu.ala.phe; phe(pro, leu,glu), and pro(leu,glu,phe). Earlier investigations[1,9,10] showed that the single leucine residue is located in the C-terminal portion of the molecule, and that two of the three serine residues and one of the three phenylalanine residues occur in the sequence ser.tyr.ser.met.glu.his.phe . . . at the N-terminus. Thus, the following sequence can be deduced for the carboxyl end of α-corticotropin: . . . asp.glu.ala.ser. glu.ala.phe.pro.leu.glu.phe.

## Action of Trypsin

50 mgm. of α-corticotropin trichloroacetate and 0·75 mgm. of crystalline trypsin were dissolved in 5 ml. of water and the *p*H of the solution was adjusted to 9·3–9·4 by the dropwise addition of 2 per cent ammonia. The whole solution was then diluted to 10 ml. with water and kept at 38° for 6 hr. After incubation, the digest was immediately lyophilized. The lyophilized product was submitted to chromatography on paper in the first dimension, in the solvent system *n*-BuOH/HOAc/$H_2O$/pyridine (30 : 6 : 24 : 20) of Waley and Watson[11], and then, in the second dimension, to zone electrophoresis on paper for 6 hr. at 11·5 volts per cm. in the buffer system γ-collidine/HOAc/$H_2O$ at *p*H 7·0, described by Lockhart and Abraham[12]. When the paper was sprayed with ninhydrin, the typical pattern shown in Fig. 2 was revealed. The material corresponding to each spot in the pattern was accumulated by submitting the digest first to paper chromatography and then to paper electrophoresis with the aforementioned solvent systems. The eluate from each zone obtained in the

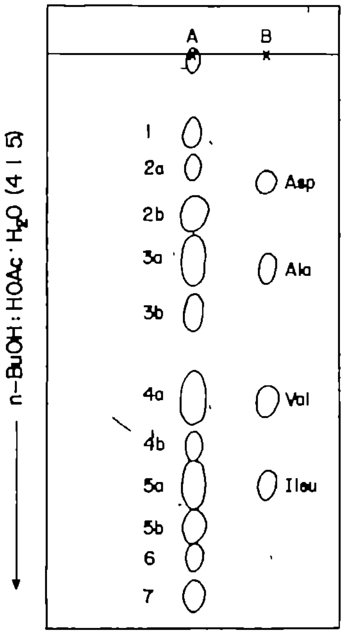

Fig. 1. Chromatogram of trichloroacetic acid-soluble peptides released by the action of pepsin on α-corticotropin

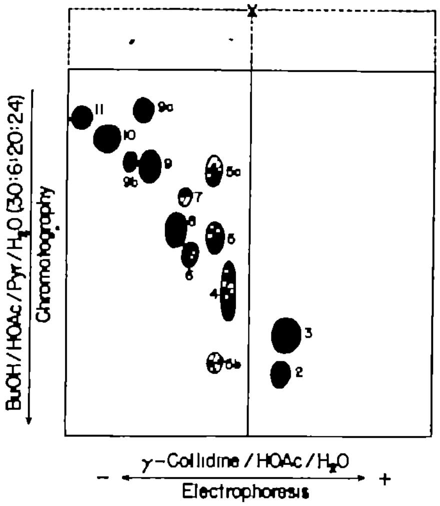

Fig. 2. Resolution of a tryptic digest of α-corticotropin by paper chromatography in the first dimension and by zone electrophoresis on paper in the second dimension

latter procedure was submitted to quantitative amino-acid analysis by the DNP-paper method[6], as well as to stepwise degradation, proceeding from the amino end of the peptide, by a modification[13] of the method of Edman[14]. Results disclose the occurrence of the following peptides in the tryptic digest of α-corticotropin: ser.tyr.ser(met,glu,his,phe)arg; try.gly.lys.pro.val.gly.lys; lys.arg; lys.arg.arg; arg.pro.val.lys; and val.tyr.pro.ala.gly.glu(asp$_2$,glu$_3$,ala$_2$,ser,phe$_2$,pro,leu).

## Action of Chymotrypsin

50 mgm. of α-corticotropin trichloroacetate was dissolved in 2 ml. of water and mixed with 2 ml. of 0·2 *M* ammonium acetate buffer, at *p*H 8·2, containing 0·5 mgm. of crystalline chymotrypsin. After the mixture had been kept at 38° C. for 4·5 hr., it was placed in a boiling water-bath for two minutes to terminate the enzymatic activity. The slight coagulum formed was removed by centrifugation and the clear supernatant liquid was lyophilized. The digest was then submitted to zone electrophoresis on paper in a γ-collidine/HOAc/H$_2$O buffer of *p*H 6·7[12] for 6 hr. at a potential gradient of 10·2 volts per cm. Fig. 3 presents a typical pattern after the paper strip had been sprayed with ninhydrin; the bands were further examined by means of stain reactions for tryptophan[15] and arginine[16]. It was found that band No. 7 gave the strongest colour reaction for these two amino-acids. The material in band No. 7 was then eluted with 3 per cent ammonia and submitted to chromatography on paper in the solvent system of Partridge[4]. The material from the main spot in the chromatogram was eluted and examined by a modification of the Edman procedure (Geschwind, I. I., unpublished work). The results gave evidence for the presence of the sequence . . . arg.try . . . in this peptide. (The sequence his.phe.arg.try . . . was found by applying the paper-strip modification[17] of the Edman procedure to a fraction obtained from countercurrent distribution of the core derived from extensive digestion of α-corticotropin with pepsin. This sequence confirms the arg.try linkage.)

## Partial Acid Hydrolysis of DNP-α-Corticotropin

The DNP-derivative of α-corticotropin was prepared according to the procedure previously described[18]. 50 mgm. of DNP-α-corticotropin was suspended in 1 ml. of 6 *M* hydrochloric acid; the suspension was sealed in a test-tube and kept at 110° C. for 5 hr. The separation and identification of DNP-peptide fragments in the partial acid hydrolysate were effected by paper chromatographic procedures similar to those employed for separating the products of peptic digestion (*vide supra*). This procedure disclosed, *inter alia*, the peptides pro(val$_2$,lys,tyr) and ala(gly,glu,asp); the quantitative estimations were

Table 1. PEPTIDES OBTAINED FROM PEPTIC, TRYPTIC, CHYMOTRYPTIC, AND PARTIAL ACID DIGESTS OF α-CORTICOTROPIN: COMPLETE AMINO-ACID SEQUENCE OF THE PEPTIDE HORMONE

| Hydrolytic agent | Peptide No. | Amino-acid sequence |

nade visually on the basis of ninhydrin-sprayed hromatograms.

Table 1 summarizes the results obtained from eptic, tryptic, chymotryptic, and partial acid ydrolysates of α-corticotropin. From them, together vith previously reported sequences for the N- and -terminus[8], the complete amino-acid sequence of he hormone is established. Since no amino-acid equence inconsistent with this formulation was ncountered, it may be assumed that no appreciable ranspeptidation has occurred during enzymatic ligestion. Although no structure containing the equence . . . lys.lys . . . has been found, there is vidence to suggest that the linkage postulated in ositions 15–16 must exist. The specificity of trypsin vould demand that the . . . gly.lys . . . bond (positions 4–15) not be split. Consequently, the N-terminal ysine of peptides 10 and 11, which together with eptide 8 are found in high yield, cannot represent osition 14 and hence must occupy position 15. It hould be noted that the location of the amide groups n the molecule has not been established. Previous tudies[19] have shown that α-corticotropin contains wo amide residues.

Recently, Bell and his co-workers[20] reported the urification and structure of β-corticotropin from iog pituitary glands. Both the ovine and the porcine iormones contain 39 amino-acids, the only difference eing the occurrence of one less serine and one more eucine in β-corticotropin; this difference is accounted or by the . . . ala.ser . . . sequence (positions 31–32) n the sheep hormone in place of a . . . leu.ala . . . equence in the porcine β-corticotropin. The only ncertainty reported in the structure of the latter[20] vas in the sequence . . . ala(gly,glu,asp) . . . in ositions 25–28. White and Landmann[21] reported he sequence . . . gly.ala.glu.asp . . . in these positions n corticotropin-*A*, which is also of porcine origin. n the ovine hormone, the sequence for these positions, as shown in Table 1, is: . . . ala.gly.glu.asp. Some uncertainty about the sequence of positions 25–28 was introduced when peptides 2 and 3 in the tryptic digest were re-investigated by the Edman procedure. However, a single experiment with acid hydrolysis (*WOH-4*) favoured the proposed sequence. Further investigation is being carried out.

Complete details will be published elsewhere.

We wish to acknowledge with thanks the generous support of the National Institutes of Health, the United States Public Health Service (Grant No. *G* 2907), the Albert and Mary Lasker Foundation, and Eli Lilly and Company, which have aided greatly in the present investigation.

# FORMATION OF TUBES BY A SIMPLE ROLLING ACTION: A NEW NORMAL-PRESSURE EFFECT

By M. J. EGAN and A. JOBLING

Ernest Oppenheimer Laboratory, Department of Colloid Science, University of Cambridge

IN the steel industry, it is known that, in the Mannesmann process[1], a red-hot rod of metal orms itself into a tube when rolled between rollers. Villiamson[2] has recently described a similar phenmenon which he observed in the rolling of a certain iatural Australian clay ('blue ball clay') and also vith warm 'Plasticine'. He studied in great detail the nicrostructure of the clay with regard to its chemical onstitution, water content, and particle size, shape nd crystallographic orientation, and concluded that he phenomenon was specific to the microstructure nd in particular to the difference in water content etween the inner and outer regions of the specimen.

Weissenberg[3] has analysed the experimental obserations and concludes from his theory of flow that he phenomenon should depend only on the macrocopic characteristics of the process and the material, nd should be much more general than has hitherto een imagined. It should be observable as an effect f normal pressure in materials with the most varied ypes of microstructure and be particularly sensitive to the amount of elastic recovery present. When this amount approximates to zero, the plastic deformation caused by the rolling process should generate near the axis of the specimen a concentration of tensional normal pressures which suck in the end-planes of the specimen and open up radial cracks. This could continue under favourable conditions until a tube is formed. Tests with elastic recoveries progressively increasing from zero to large amounts should produce plastic and elastic deformations, and the latter should reduce the strength of the tensional pressures to zero and beyond this to compressions. Thus, in extreme cases, a reversion of the phenomenon of tube formation should be observed, as the compressions would tend to push out the end-planes of the specimen. The early stages of the sucking-in or pushing-out should be insensitive to changes in the initial shape of the specimen, but the completion of a tube by continued rolling should be facilitated by the choice of initial dimensions with a length to width ratio smaller than unity.

We were interested in testing Weissenberg's conclusions, particularly because it seemed unlikely that a merely macroscopic theory could predict qualitatively all the various widely differing normal pressure effects such as these and the better-known 'Weissenberg effects'[4,5] which occur under torsional shears and are almost diametrically opposed to those described here. Two series of tests were carried out.

We started the first series by reproducing and confirming Williamson's observations. We rolled tubes from warm 'Plasticine' and from an aqueous paste of a clay very similar in constitution to his 'blue ball clay'. Both materials had a macroscopic consistency which was putty-like and plastic, with no apparent elastic recovery. We then prepared a series of materials of similar macroscopic consistency but with widely differing microscopic structures by stirring liquids into aggregates of solid particles to a solid concentration of about 75 per cent (though this was not very critical). The rolling of flat-ended cylindrical specimens with a length to diameter ratio of about 0·5 produced tubes in every material of this series irrespective of the nature of the liquid phase (water, paraffin oil, or silicone oil) or whether the solid particles were coarse or fine, crystalline or amorphous, in the shape of plates (graphite), needles (asbestos), or spheres (starch). The effect of varying the dimensions of the specimen was most pronounced in cold 'Plasticine', from which Williamson failed to produce a tube. In this material we produced tubes by rolling cylindrical rods with initial length/diameter ratios equal to or smaller than 0·5, and found that the rolling of spheres and cylinders with a ratio equal to or larger than 1 (such as were used by Williamson) exhibited in the early stages a drawing-in of the ends; but the end cavities did not meet however long the rolling continued.

The appearance of cracks during rolling allowed a rough assessment of the pressure distribution to be made. An accumulation near the axis of tensional normal pressures was indicated by the opening-up of radial cracks originating near the axis and decreasing in width from the centre outwards (see Fig. 1). The effects of varying the chemical and physical properties of the components were difficult to assess; but, in a qualitative way, it was possible to distinguish two types. One type formed tubes by the sucking-in of the ends of the cylinder until the concavities met; for example, smooth pastes containing, in 'Nujol' (liquid paraffin): powders of aluminium, aluminium stearate, cement, clay, cornflour, graphite, icing sugar, iron, jeweller's rouge, lycopodium, polystyrene, 'Pyrex' glass, starch, and talc; in water: clay, icing sugar, lithopone; in silicone oil: graphite, icing sugar. The other type formed tubes by the opening-up of radial cracks with little or no drawing-in of the ends; for example, fibrous pastes of 'Nujol' and asbestos or of water and filter-paper pulp.

In a second series of tests, we investigated materials with a macroscopic consistency which was again putty-like but showed noticeable amounts of elastic recovery (as evidenced by bouncing or recovery from stretching) in contrast to the first group. Some extreme cases of such materials are a polyisobutylene with a molecular weight of about 20,000, silicone bouncing putty, and Reeves's 'putty' rubber, all of which on rolling produced elongated rods with convex ends and thus exhibited the opposite of the tube-forming phenomenon. Tests of the remaining materials in this series (Remington 'Everclean' rubber, and pastes of 'Plasticine' + rubber solution + talc, and vinyl chloride-acetate copolymer + dioctyl phthalate + china clay) showed poor reproducibility. The same material exhibited in successive experiments both drawing-in of the ends and the converse effect even with no deliberate variation of the experimental conditions. An assessment of these results has to be postponed until quantitative data are available under carefully controlled conditions of temperature, speed and pressure of rolling, etc.

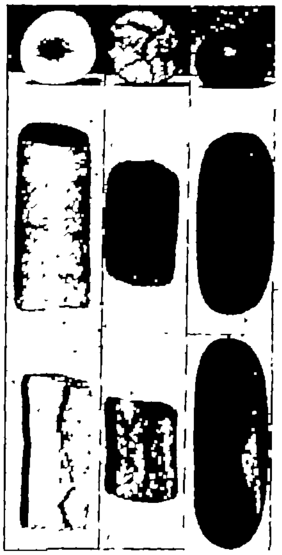

Fig. 1. Tube formation and its opposite in different types of materials. The rolled specimens are viewed in elevation (top), plan (middle), and axial section (bottom). From left to right: cornflour in 'Nujol', asbestos in 'Nujol', polyisobutylene with a molecular weight of about 20,000

Fig. 1 illustrates the normal-pressure phenomena observed in rolling. Tube formation of the two types is shown in two materials of the first series of tests and the opposite phenomenon in an extreme material of the second series.

These two series of tests do not provide sufficient information to decide for or against Weissenberg's theory. However, such indications as have been obtained are consistent with his predictions of an accumulation of normal pressures near the axis of the specimen, and of a change of the pressures from tension to compression with an increase in the amount of elastic recovery. In any event, the application by Weissenberg of the macroscopic point of view has revealed the great generality of a new set of normal-pressure phenomena occurring in the shearing movement of the rolling process.

We thank Mr. A. J. Gaskin, of the Commonwealth Scientific and Industrial Research Organization, Melbourne, in whose department Williamson's experiments were performed, for bringing the phenomenon to our notice and for his continued interest and co-operation. We thank also Mr. J. E. Roberts and Mr. W. F. O. Pollett for help and advice in the experimental investigation, and Dr. J. H. Schulman for useful discussion about the materials under test. A number of firms and individuals have generously provided samples of powders of known size and shape.

## A Measurement of the Earth's Magnetic Field by Nuclear Induction

EXPERIMENTS have been carried out recently to measure the total magnetic field in the vicinity of Christchurch, Hants, using the free precession technique briefly reported by Packard and Varian[1].

In these experiments, the protons in a sample of water are initially polarized magnetically at right angles to the earth's field, and then the polarizing field switched off non-adiabatically. The residual magnetic vector is free to precess about the earth's magnetic field $F$, and in so doing induces a signal voltage in a pick-up coil. The frequency $f$ of the precession is simply related to the field by the equation

$$2\pi f = \gamma_p F,$$

where $\gamma_p$ is the gyromagnetic ratio for the proton.

The frequency $f$ at this particular site at Christchurch at 12.30 p.m. on June 30, 1955, was 1,997·22 c./s., which corresponds to a value for $F$ of 0·46906 ± 0·00001 gauss.

The frequency was measured in a simple manner by beating the input signal with the second harmonic of a 1,000 c./s. valve-maintained tuning fork checked against Rugby and B.B.C. to about 1 part in $10^6$. The beat pattern was photographed from the cathode-ray oscilloscope display and, by comparison with a crystal-derived 50-c./s. trace, estimated to 1 part in 300. The beat frequency was 2·784 ± 0·005 c./s., hence the error in precession frequency is only 1 part in $4 \times 10^5$. Since the latest available value[2] of $\gamma_p$ is 26,753 ± 0·6 sec.$^{-1}$ gauss$^{-1}$, the computed value for the total magnetic field is therefore limited by this. The value of $F$ obtained is the time average over the period of an observation, about 5 sec.

For relative measurements, where the value of $\gamma_p$ is not required, differences of the order of 1 microgauss should be just detectable.

The experiment recommends itself for its extreme simplicity. The apparatus consists of a rugged and portable nuclear magnetometer head, requiring no careful orientation in setting up, and standard frequency-measuring equipment. Placing the head on a selected site and taking a reading requires only a few seconds.

The experiment does, incidentally, provide a striking means of demonstrating the nuclear relaxation times $T_1$ and $T_2$.

Full details of the method and results will be reported elsewhere.

## Colour of Tellurite Glasses

THE glass-forming properties of tellurium dioxide, and the interesting properties of some tellurite glasses have been described by Stanworth[1]. Certain of these glasses have possible applications as optical components owing to their high refractive indices. However, all the tellurite glasses were prepared using commercially available tellurium dioxide and were coloured, usually slightly, yellow-green. This is in contrast to the statement of Berzelius[2] that clear, colourless glasses could be made by fusing the tetra-tellurites of barium and the alkali metals.

It was considered probable that the colour of the glass originated from impurities present in the tellurium dioxide. Spectrographic examination showed that the amount of impurity in the glasses was very small, that calcium and strontium were the main impurities and that slight traces of aluminium, magnesium, sodium, iron and gold could be detected. Of these it was judged that iron was by far the most probable source of the coloration. Chemical analysis of some tellurite glasses for iron gave values between 0·004 and 0·007 per cent for the total iron expressed as $Fe_2O_3$, in the glasses exhibiting least colour.

A number of attempts were then made to prepare a sample of pure $TeO_2$, particular reference being paid to the iron content. According to Köthner[3], tellurium metal may be separated from all impurities, except antimony, by repeated distillation under reduced pressure. This method was applied by distilling tellurium (50 gm.) in a bent quartz tube connected to a water-jet pump. Half the tube was heated in a small electric furnace, and the middle fraction of the distillate was collected at about 650° under 20 mm. mercury pressure. This procedure was repeated four times. The product was converted to the oxide $TeO_2$, via the basic nitrate, by the method described by Marshall[4], thus effecting a further purification.

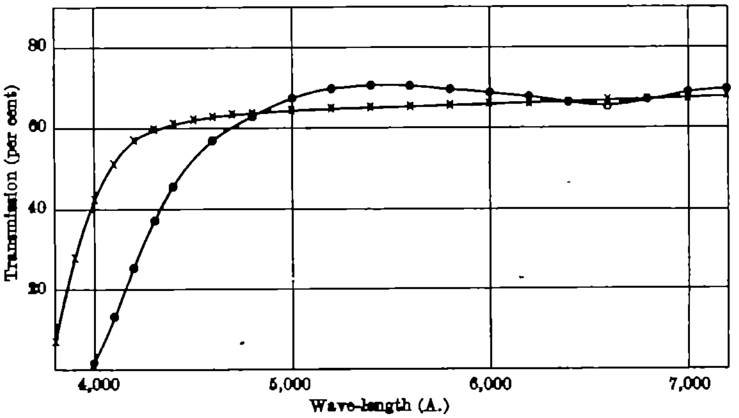

Fig. 1. Spectral transmission of barium tellurite glass of molecular composition BaO.8TeO$_2$. ○, Melted in gold, using commercial tellurium oxide; ×, melted in gold, using purified tellurium oxide

Glasses of molecular composition BaO.8TeO$_2$ were melted from 'Analar' barium carbonate and various samples of $TeO_2$, and it was immediately evident that the $TeO_2$ purified as above gave glasses with much reduced colour. All the glasses were melted for 10 min., in a gold crucible at 900°, and were afterwards annealed from 310°. The glasses were ground and polished to a thickness of 3·5 mm. and the visual transmission curves obtained. The curves relating to two glasses, one melted from commercial $TeO_2$ and the other melted from purified $TeO_2$, are shown in Fig. 1. Chemical analysis of these glasses showed that they contained respectively ~ 0·004 per cent and ~ 0·001 per cent iron, expressed as $Fe_2O_3$. Examination of the curves shows that with increasing purity of the glass, the ultra-violet absorption edge shifts towards shorter wavelengths. This is consistent with a decrease in proportion of ferric iron in the glass. Thus, it is concluded that the yellow-green colour of tellurite glasses melted from commercial materials is due to traces of iron impurities, and that the coloration may be greatly diminished by using a purer form of $TeO_2$.

It should be pointed out that the refractive index of the glass of composition $BeO.8TeO_2$ is approximately 2·1. Thus, there occurs during the transmission measurements a loss by reflexion at both surfaces amounting to about 24 per cent. This explains, in part, why the overall transmission of the glasses is low.

## A Method of determining Particle Size of Powders

Mills[1] recently described an apparatus for determining the mean diameter of the particles of a powder. This method, based on the measurement of the capillary pull of the interstitial pores, is not applicable in the case of very fine particles, since $h$, the capillary pull, cannot exceed the barometric height and $l$, the length of the column of the powder, must be kept as short as possible. The present communication describes in brief an alternative method (based on permeability principles) which is free from this limitation. The apparatus is illustrated in Fig. 1.

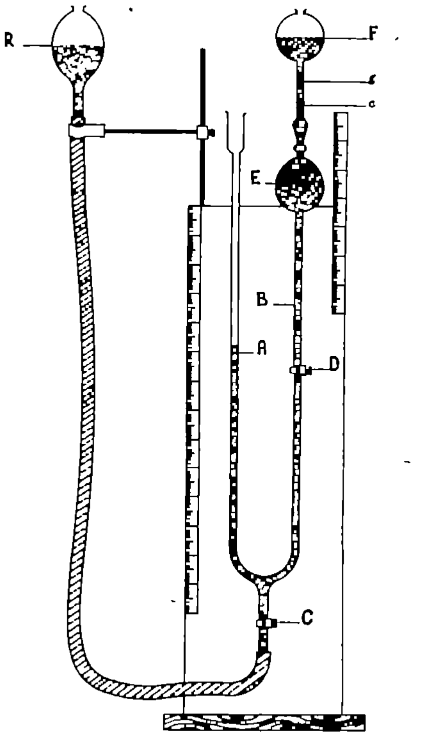

Fig. 1

By opening the stopcock $C$, mercury from the reservoir $R$ is introduced into the apparatus until the bulb $E$ (about 25 c.c. capacity) is almost half full. The rest of the bulb $E$ is filled with air-free water (or any other suitable wetting liquid). The powder under examination is closely packed over a plug of cotton or any other fibrous material of surface area much less than the powder at the constriction $c$, in the stem of the bulb $F$ (25 c.c. capacity). The bulb $F$, detached from the main apparatus at the ground-glass joint, is then connected to a vacuum system at the lower end and water (or whatever wetting liquid is used) is poured in from above. The air contained in the pores of the powder is thereby replaced by the wetting liquid. The bulb is then mounted on the apparatus as shown in Fig 1. This ensures an air-free joint. Sometimes tiny bubbles of air may appear at the bottom of the cotton plug on the removal of the bulb $F$ from the vacuum system. These can be removed by simple manipulation.

The stopcock $D$ is then closed and the mercury reservoir $R$ is lowered. When the difference in the mercury levels in the tubes $A$ and $B$ is about 50 cm. the stopcock $C$ is closed and $D$ is opened. Thus a certain amount of pressure deficiency is applied at the powder end and the liquid begins to flow through it. The level of mercury in the tube $A$ begins to rise. The time ($t$) taken by the mercury level to rise through a given length, say, 5 cm., is noted. Applying Poiseuille's equation with suitable modifications for flow of liquids through porous media[2], and taking into account the flow under gradually decreasing pressure head, as in the present case, the following expression can be deduced:

$$r = \frac{1 - \varepsilon}{\varepsilon} \sqrt{\frac{0\cdot006905\ L\eta R_1{}^2}{\varepsilon R^2 t} \log \frac{l_0}{l}}$$

where $r$ is the mean particle radius, $\eta$ is the coefficient of viscosity of the wetting liquid, $R_1$ is the radius of the tube $A$, $R$ is the radius of the tube $g$, $l_0$ is the initial and $l$ the final difference in the mercury levels in the two limbs, and $\varepsilon$ is the pore space per c.c. of the powder.

The method was tested on several powders, varying in mean diameters from 0·015 to 0·0005 mm. Water and benzene were used as experimental liquids. The results obtained with both these liquids were in fairly good agreement with one another. The mean diameters were also calculated by microscopic counts and by Mills's method wherever it was applicable. The values obtained by the various methods were found to be of the same order.

## Growth Spirals in Electrodeposited Copper

It was first pointed out by Frank[1] that the termination of screw dislocations in a crystal face would produce steps, by the propagation of which crystal growth could take place. Such steps would obviate the need for two-dimensional nucleation and thus allow crystal growth to proceed at considerably lower supersaturations than those required to form two-dimensional nuclei. Frank predicted that the presence of an isolated dislocation on a close-packed crystal face would allow this to grow *ad infinitum* in the form of an ascending spiral. This prediction was afterwards substantiated experimentally by observations of crystals grown both from the vapour and from solution. The spirals of silicon carbide grown from the vapour by Verma[2], and those of cadmium iodide grown from solution by Forty[3] may be quoted as examples.

No observations of spirals grown by electrodeposition seem, however, to have been reported. A recent examination of the surface of electrodeposited copper has led to the identification of spirals, and these must be assumed to have originated in a manner similar to that discussed in the previous paragraph. The copper was deposited at an average current density of 10 m.amp./cm.$^2$ on a polycrystalline sheet of copper which had been cold-rolled and annealed so that a high proportion of the grains were oriented with their (100) planes parallel to the surface of the sheet and their [001] directions parallel to the rolling direction. The cathodes were electropolished prior to plating.

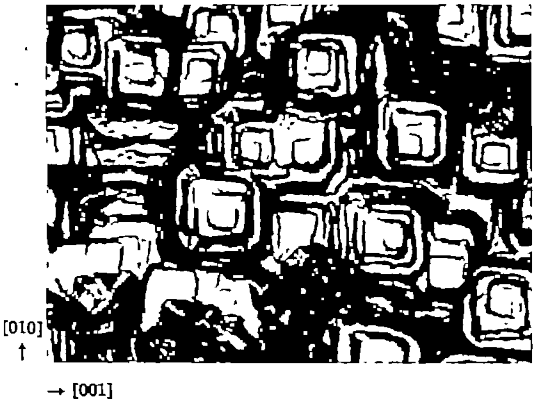

Fig. 1. Growth spirals in copper electrodeposited from an acid copper sulphate bath. (× 570)

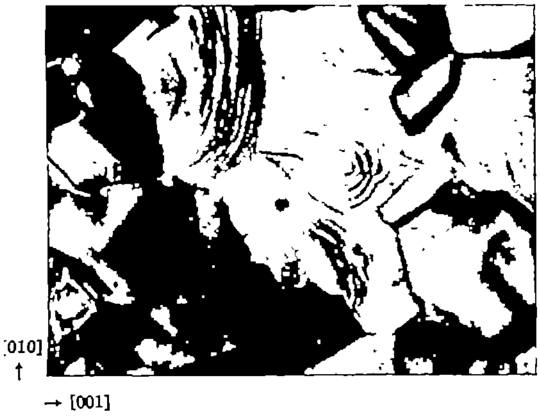

Fig. 2. A growth spiral in copper electrodeposited from a neutral copper sulphate bath. (× 940)

Two types of spiral have been observed: (*a*) those deposited from aqueous $N/2$ copper sulphate + $N/2$ sulphuric acid solution, in which the rate of growth appears to have varied with crystallographic direction (see Fig. 1); (*b*) those deposited from neutral aqueous $N/2$ copper sulphate, in which growth was insensitive to crystallographic direction (see Fig. 2).

The conditions under which these spirals grow are now the subject of investigation. Plans are in hand to produce a continuous photographic record of the development of these spirals and of other features of crystal growth encountered in electrodeposition. This will be done by placing a suitably designed electrolytic cell on the stage of a microscope fitted with a reflecting objective. Such an objective may easily be corrected for the refractive index of the plating solution.

Since writing this communication, my attention has been directed to a photograph of a spiral on the surface of electrodeposited silver–indium alloy, reproduced in a paper by Raub[4]. This spiral is visible to the naked eye, but no details are given of the way in which it has been produced.

## Partition Chromatography of Synthetic Detergents

In the course of a study on the adsorption at liquid/solid and liquid/air interfaces, difficulties were encountered in identifying small quantities of adsorbed detergents and in separating mixtures of such substances containing alkyl groups differing in length.

A convenient method of separation has now been developed by means of paper partition chromatography. The compounds mainly dealt with were the normal sodium alkyl sulphates, the number of carbon atoms in the hydrocarbon chain ranging from twelve to eighteen. However, with minor modifications the method was successfully applied to alkyl aryl sulphonates, secondary alkyl sulphates, quaternary ammonium and pyridinium salts.

The methods of ascending and circular[1] chromatography were employed. Whatman No. 1 filter paper was impregnated with a long-chain fatty alcohol, usually cetyl alcohol, which acted as stationary phase; this was applied from a 1 per cent ethanolic solution. The mobile phase consisted of an aqueous ethyl alcohol solution saturated with cetyl alcohol. The concentration of this solution varied according to the alkyl sulphates to be separated. The chromatogram of the detergent mixture was developed for 10–24 hr., and the paper dried. It was then immersed in 0·5 per cent cupric acetate and sprayed with a 0·05 per cent solution of rhodamine 6*GB*. After drying, the detergent spots appeared crimson on a pink background in daylight, and dark purple on a yellow background under ultra-violet light. $R_F$ values were determined for various concentrations of ethyl alcohol and are shown in Table 1.

Table 1

| Concentration of ethanol | No. of carbon atoms in n-alkyl group | | | |
|---|---|---|---|---|
| | 12 | 14 | 16 | 18 |
| 50 | 0·88 | 0·50 | 0·11 | 0 |
| 62 | 1·0 | 0·70 | 0·39 | 0·07 |
| 75 | 1·0 | 0·90 | 0·50 | 0·15 |

By a similar procedure applied to 'Teepol', it was possible to obtain resolution into six well-defined components. It was, however, necessary to reduce the concentration of the mobile phase owing to the high solubility of secondary alkyl sulphates in ethyl alcohol. Resolution of commercial cetyl pyridinium chloride was also achieved by the above method, when four distinct compounds were obtained; the indicator used for cationic compounds was bromocresol green.

Other solvent systems are now being investigated, as well as a method for continuously changing the composition of the mobile phase, to achieve yet better separation and to enable quantitative determinations to be made.

A full account of this work will be published elsewhere. I wish to thank Mr. R. E. Wagg for helpful discussion and the Director of the British Launderers' Research Association for permission to publish this communication.

# Probable Nature of an Artefact in the Paper Chromatography of Thyroxine caused by Trichloracetic Acid

Interference of trichloracetic acid with the paper chromatography of adrenaline analogues and of histamine, using *n*-butanol/acetic acid/water (4 : 1 : 5), has already been reported[1,2]. A similar artefact is described below, affecting another compound, thyroxine, run in a different solvent system, *n*-butanol/dioxane/2 *N* ammonia (4 : 1 : 5). No effect of this nature is mentioned by Gross[3] in his review on the chromatography of thyroid hormones.

Shepherd and West[1] have been successful in removing trichloracetic acid from aqueous solutions before chromatography by treatment with the anion exchange resin 'Amberlite *IRA*-400'. Nevertheless, it was felt that an alternative method might prove useful in certain cases. Since trichloracetic acid is a strong acid, having a *pK* of 0·7 (Bell[4]), it seemed likely that electrolytic desalting would extract trichloracetate from aqueous solution, although neither Consden, Gordon and Martin[5] nor Dent[6] indicate whether the procedure is applicable to this ion. Consequently, an examination of this question was undertaken.

The thyroxine artefact was first encountered in experiments intended to discover whether the precipitation of plasma proteins by trichloracetic acid could cause the iodination of unsaturated plasma lipids by radioactive inorganic iodide; the possibility of this process occurring had been suggested by some observations on the behaviour of pure substances[7]. A plasma sample, which contained 0·1 mgm. heparin/ml., was obtained from a thyrotoxic patient who had received 10 mc. of radioiodine 48 hr. previously. A portion of this plasma (2 ml.) was treated with 20 ml. of 10 per cent (w/v) trichloracetic acid and the precipitated proteins washed three times with 10 per cent (w/v) trichloracetic acid. The precipitate was suspended in 5 ml. of water, brought to pH 4 with 1 *N* sodium hydroxide and extracted successively with 15 ml., 10 ml. and 5 ml. of water-saturated *n*-butanol and the extracts combined. Another 2-ml. portion of plasma was brought to pH 4 with 2 *N* hydrochloric acid and extracted directly. The *n*-butanol extracts were evaporated to dryness on a water-bath at 80° under reduced pressure and each residue taken up in 1 ml. of *n*-butanol. For chromatography, 50-µl. samples of these extracts were dried, 10 µl. at a time, on to a sheet of Whatman No. 1 paper, 100 µgm. of thyroxine being added as carrier to certain of the spots. The chromatogram was developed for 18 hr. in *n*-butanol/dioxane/ammonia using the descending method. The radioautograph of Fig. 1 was then prepared by placing the chromatogram in contact with 'Ilfex' double-coated X-ray film for 48 hr. Distortion of the thyroxine spot is seen to originate from those extracts which contain trichloracetic acid and spreads to adjacent runs which contain no trichloracetic acid.

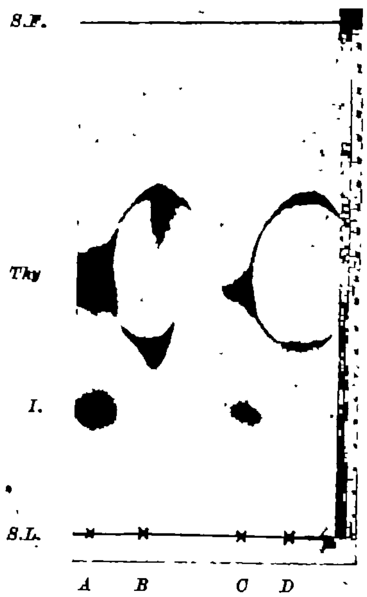

Fig. 1. Radioautograph showing trichloracetic acid interfering with the chromatography of endogenous radioactive thyroxine in extracts of plasma and plasma proteins. Scale in cm.; *S.F.*, solvent front; *S.L.*, starting line; *Thy.*, thyroxine; *I.*, iodide. (*A*) Original plasma; no trichloracetic acid; thyroxine carrier (100 µgm.). (*B*) Protein precipitate containing trichloracetic acid; thyroxine carrier (100 µgm.). (*C*) As (*A*) without carrier. (*D*) as (*B*) without carrier

The efficiency of the electrolytic desalting process was tested by noting how the chromatography of 50 µgm. thyroxine was affected by 50 µl. of a 2·5 per cent (w/v) trichloracetic acid solution before and after electrolysis of the latter for 1 hr. in a commercial model (supplied by the Shandon Scientific Co., London) of Dent's[6] desalter (initial current 0·9 amp.). The trichloracetic acid (in five portions) and thyroxine solutions were dried separately on to each spot and the chromatograms were developed for 21 hr. in *n*-butanol/dioxane/ammonia using the ascending method. Thyroxine was detected by spraying the paper with 0·2 per cent (w/v) ninhydrin in water-saturated *n*-butanol and heating it at 90° for 5 min.

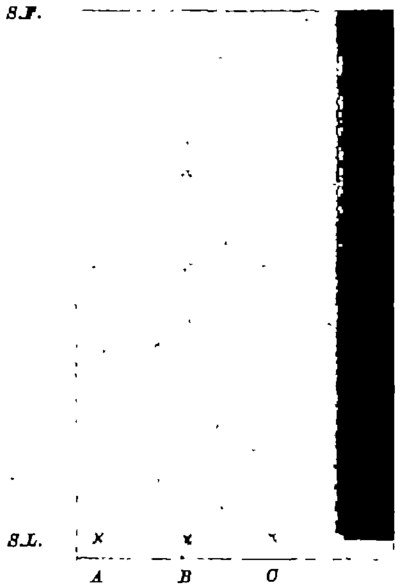

Fig. 2. Chromatogram showing the effect of trichloracetic acid on thyroxine chromatograms before and after electrolytic desalting. Scale in cm.; *S.F.*, solvent front; *S.L.*, starting line. (*A*) Thyroxine (50 μgm.) alone. (*B*) Thyroxine (50 μgm.) and 50 μl. of 2·5 per cent trichloracetic acid before electrolysis. (*C*) Thyroxine (50 μgm.) and 50 μl. of 2·5 per cent trichloracetic acid after electrolysis

Fig. 2 shows that electrolytic desalting causes the 'double spot' artefact to disappear. However, trichloracetic acid is probably not completely removed, since spot (*C*) shows an increase in the $R_F$ of thyroxine relative to spot (*A*). Incomplete desalting has been observed in the case of other ions and is treated theoretically by Consden, Gordon and Martin[5].

There are two possible reasons why trichloracetic acid might cause chromatographic artefacts. Either loose chemical combination might take place between it and one or more of the substances being chromatographed[1,2], or the acid could interfere with the chromatographic solvent system. The form and spread of the artefacts shown in Fig. 1 favour the latter explanation. In this connexion it should be noted that solvent systems containing *n*-butanol are highly sensitive to changes in the degree of saturation of the non-aqueous with the aqueous phase[8], and it seems likely that trichloracetic acid, which is strongly hygroscopic, could cause such changes to occur.

I wish to thank Dr. H. Miller for preparing the radioautograph, Prof. G. M. Wilson and Dr. D. R. Wood for their interest in this work, and the Board of Governors of the United Sheffield Hospitals for financial assistance.

## Decomposition Flame of Methyl Nitrite

WHEN a stream of methyl nitrite vapour issuing from the mouth of an upright cylindrical glass tube about 5 cm. in diameter is ignited it burns in the air as a lambent diffusion flame, greyish-yellow in hue. At the inner surface of the diffusion flame an orange-red zone forms as a cone at the mouth of the tube. If the rate of flow is reduced, this orange-red inner flame peels away from the diffusion flame and slowly descends the tube as a flat disk surmounted by a fainter, conical afterglow of the same colour, easily visible in a darkened room. No oxygen is necessary for its propagation. After it has entered the tube it is not affected if the diffusion flame at the mouth is extinguished. It is the decomposition flame of pure methyl nitrite.

The decomposition flame is not propagated downwards in tubes with diameters much less than 2 cm. In wider tubes it may be stabilized at any point by adjusting the rate of flow. Its speed, measured in tubes of 3·9 and 6·2 cm. diameter, is about 3·0 and 2·5 cm. sec.$^{-1}$ respectively. In the presence of small amounts of oxygen or of ammonia, the flame burns more readily without any obvious alteration in its nature.

From the decomposition flame formaldehyde is liberated and condenses (as paraformaldehyde) on the walls of the tube downstream of the flame. Farther from the flame a brown, resinous tar is deposited. Nitric oxide is also present and forms, in the air above the flame, the familiar brown fumes of nitrogen dioxide. In a cylindrical tube of this type, the decomposition flame is too faint for convenient emission spectroscopy. An attempt was made to maintain the same flame under conditions in which the flame would be brighter and thus more suitable for spectroscopy by establishing the premixed oxygen – methyl nitrite flame on a sintered-disk burner and then cutting off the oxygen supply. On a 2·8-cm. diameter burner it was possible to reduce the oxygen/nitrite ratio to only 0·1 mole per mole and to maintain a flame very closely resembling the decomposition flame in a tubular burner. The odour of formaldehyde was again marked and a white smoke of paraformaldehyde visible. Absorption spectroscopy showed that nitric oxide passed through the flame without undergoing complete reduction. Relatively little oxidation occurred, and this flame, although maintained in part by oxygen, was primarily the decomposition flame of methyl nitrite.

A related phenomenon may be recognized on the nitrite side of the oxygen – methyl nitrite diffusion flame[1]. Far from the oxygen supply an orange-red zone of flame is formed. Absorption spectroscopy shows that nitric oxide is formed on the nitrite side of this zone, where the absorption by the nitrite begins to fade away, and that it is consumed in the zone itself, obviously by reaction with organic breakdown products of the nitrite, because CN and NH bands are observed in emission.

Although the thermal decomposition of the simple alkyl nitrites has recently been shown to be accompanied by chemiluminescence[2], this is a remarkable and unexpected flame. Its precarious existence is emphasized by the large quenching diameter; its burning velocity—about 3 cm. sec.$^{-1}$ at atmospheric pressure—makes it perhaps the slowest flame known. According to Steacie[3] and to Rice and Rodowskas[4], the normal thermal decomposition of the alkyl nitrites begins by O—N bond fission

$$RCH_2ONO \rightarrow RCH_2O + NO \quad E_{act} \sim 37 \text{ k.cal.} \quad (1)$$

and ends with the formation of aldehyde, alcohol and nitric oxide:

$$RCH_2ONO \rightarrow 0{\cdot}5\, RCH_2OH + 0{\cdot}5\, RCHO + NO \quad \Delta H \sim 0 \text{ k.cal.} \quad (2)$$

Neither this reaction (2), which is almost thermoneutral, nor any in which there is complete conversion to nitric oxide, can account for a decomposition flame. For the release of the necessary heat some of the nitric oxide must be reduced and nitrous oxide or nitrogen formed:

$$CH_3ONO \rightarrow 0{\cdot}5\, N_2O + 0{\cdot}5\, H_2O + CH_2O \;(\text{or } CO + H_2) \quad \Delta H = -30 \text{ k.cal.} \quad (3)$$

$$CH_3ONO \rightarrow 0{\cdot}25\, N_2 + 0{\cdot}5\, H_2O + CH_2O \;(\text{or } CO + H_2) + 0{\cdot}5\, NO \quad \Delta H = -29 \text{ k.cal.} \quad (4)$$

In practice, decomposition may be expected to lie between the last three extremes.

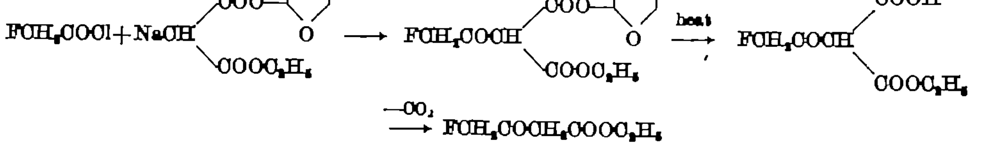
## Ethyl ω-Fluoroacetoacetate

ACETOACETIC acid is an important and widespread intermediary metabolite, being formed in the oxidative degradation of fatty acids and of certain amino-acids. For comparison with acetoacetic acid, we have prepared[1] the compound ethyl ω-fluoroacetoacetate, $FCH_2COCH_2COOC_2H_5$. From a consideration of its structural similarity to 4-fluorobutyric acid[2] and of its probable interference with the mechanism of fatty acid metabolism, we predicted that it would produce toxic symptoms.

The unequivocal synthesis, outlined below, was adapted from a previously described method[3]:



Ethyl ω-fluoroacetoacetate was obtained in 35 per cent overall yield as a colourless liquid with an odour almost indistinguishable from that of ethyl acetoacetate (b.p. 78–80° C./12 mm., and $n_D^{25}$ 1·4180; found: C, 48·64; H, 6·26; $C_6H_9O_3F$ requires C, 48·64; H, 6·08 per cent). It readily formed a 2,4-dinitrophenylhydrazone derivative (m.p. 91–91·5°; found: C, 43·71; H, 4·16; N, 17·19. $C_{12}H_{13}O_6N_4F$ requires: C, 43·90; H, 3·99; N, 17·07 per cent).

It proved to be toxic to mice (L.D. 50, c. 2·5 mgm./kgm.). Its pharmacological and biochemical properties are being examined, and may be reported at a later date.

We are grateful to Drs. M. K. McPhail, F. C. G. Hoskin and J. M. Parker for carrying out the toxicity assays. Acknowledgment is made to the Defence Research Board of Canada for funds (Contract *DRB X*-24) and for permission to publish this work (Report No. *SW*-5), and to the Research Council of Ontario for a scholarship for one of us (R. R. F.).

## Characterization and Total Recovery of the Component Proteins of a Deoxyribonucleoprotein

RECENT developments suggest that the normal nuclei of all somatic cells of an organism contain the same quantity[1] and kind[2] of deoxyribonucleic acid, but that the different cell types within the organism may differ[3] in regard to the proteins associated with deoxyribonucleic acid: deoxyribonucleic acid appears to be specific for species and the associated proteins specific for cell type. The deoxyribonucleic acid of a species has been shown[4] to be multiple with regard to nucleobase ratios and may consist of as many chemical individuals as there are genes, while at the same time among different species the deoxyribonucleic acid-associated proteins of similar organs may be similar. Classical genetics postulates that each cell type is, through its chromosomes, *endowed* with all the potentialities of the species, but *expresses* only those potentialities which make up its own specific character. If the deoxyribonucleic acids are the physical correlate of the genetic potentialities, the implication arises that cellular differentiation may be mediated through attachment of cell-specific proteins (histones, etc.) to species-specific deoxyribonucleic acids. Indeed, the hypothesis that the former function as gene conditioners was advanced by Stedman[5] long before the emergence of chemical proof for the multiplicity of deoxyribonucleic acid, and has recently been reasserted[6] on the basis of experimental evidence for the cell-type specificity of certain preparations of deoxyribonucleic acid-associated proteins.

In view of these developments, the comprehensive chemical characterization of the proteins associated with deoxyribonucleic acid of different tissues (which began eighty years ago with the work of Miescher) has attained new importance. Along with others, we have in recent years been studying the protein moiety of calf thymus nucleoprotein. We have developed a working procedure which yields essentially all of the protein associated with the deoxyribonucleic acid of calf thymus nucleoprotein, in the form of three major fractions. Quantitative recovery is shown by the fact that the products contain all the sulphur and none of the phosphorus of the thymus nucleoprotein and account for its weight after subtraction of deoxyribonucleic acid corresponding to its phosphorus content.

Thymus nucleoprotein is obtained by extraction of homogenized fresh calf thymus tissue with water at 2° for 24 hr., centrifugation and precipitation in 0·14 *M* sodium chloride, followed by several re-precipitations. Four successive preparations, made from glands obtained at the slaughter house over a one-year interval, showed in terms of dry, salt- and lipid-free thymus nucleoprotein: phosphorus 4·20 ± 0·03 per cent and sulphur 0·31 ± 0·01 per cent (av. dev.). A modified Sevag procedure, applied to the fresh, moist thymus nucleoprotein precipitate, and consisting of a series of careful extractions and re-extractions at *p*H 11·0 with 1 *M* sodium chloride[7], yields essentially all of the phosphorus-free protein. Treatment of this latter protein with hydrochloric acid of *p*H 2·5, combined with high-speed centrifugation, separates it into soluble histone and residual protein. These products, properly washed and clarified, are neutralized and lyophilized. So far, no means have been found for re-dissolving the residual protein and examining its purity.

The histone fraction has been examined by fractional precipitation and by ultracentrifugal analysis. Successive adjustment of a histone solution to *p*H 10·3, 10·5 and 11·1 yielded three fractions of similar size which did not differ significantly from the whole histone in their nitrogen/sulphur and nitrogen/tryptophan ratios. Nevertheless, ultracentrifugal analysis of the whole histone revealed two major components. The faster of the two represents 63 per cent of the histone, yields a molecular weight estimate of 140,000 and contains methionine and cystine, as well as tryptophan. The slower component corresponds to 37 per cent of the histone, has a molecular weight of 11,000–16,000 and appears to contain one molecule of methionine, but no cystine or tryptophan. Table 1 gives a condensed summary of the preparative and analytical results.

Table 1

| Fraction | Weight (per cent) | N (per cent) | S (per cent) | Methionine (per cent) | Cystine (per cent) | Tryptophan (per cent) |
|---|---|---|---|---|---|---|
| Nucleoprotein | 100 | 18·5 | 0·31 | | | |
| Whole protein | 58 | 18·4 | 0·55 | 1·70 | 0 65 | 0·32 |
| Residual protein | 9 | 18·5 | 0·70 | 1·57 | 1·34 | 0·99 |
| Whole histone | 49 | 19·6 | 0·51 | 1·69 | 0 56 | 0·19 |
| 'Fast' histone | 31 | 19·4 | 0·70 | 2 41 | 0·67 | 0·23 |
| 'Slow' histone | 18 | 18·6 | 0·20 | 0 82 | 0·09 | 0 05 |

The use of dialysis as a means of separating the 'fast' from the 'slow' histone appears attractive, but is beset with difficulties and problems. Upon continuous dialysis of whole protein or whole histone, considerably more nitrogen than that corresponding to the 'slow' histone appears permeable. Because of these observations, which await explanation and resemble those of others[6], dialysis has not been employed in our fractionation. Several other authors[8,9] have recently reported a pair of histone fractions of low and high molecular weight, and it is noteworthy and puzzling that two of the procedures (Ahlström, Hamer) included extensive dialysis.

Our 'fast' and 'slow' histones showed sedimentation constants of $s^0_{20}$ = 8·40 *S* and 1·59 *S*, respectively (2·1 per cent in 0·18 *M* sodium chloride at *p*H 8·1). The constants reported by others for the slower fraction range from 0·9 to 2·0, and for the faster one from 8·7 to 30. Because of different experimental conditions the significance of the discrepancies is uncertain. In view of the aggregative tendencies of histones[6], the wide range of values reported for the 'fast' fraction, from 8·4 for our preparation to a maximum of 30, may reflect increasing degrees of aggregation.

We wish to thank Dr. Sam Sorof, who has provided the ultracentrifugal results, and Mr. Joseph J. Kolb, who has aided in the analytical work. A detailed account will appear elsewhere[10].

The work has been aided by a research grant (No. 1249) from the National Cancer Institute of the U.S. Public Health Service, and by an institutional research grant of the American Cancer Society.

## Is Fusaric Acid a Vivotoxin?

WHILE fusaric acid has been isolated and identified from culture filtrates of a number of *Fusaria*, its detection *in vivo* in diseased host plants has not yet been achieved in order to establish its vivotoxic complicity in wilt diseases[1]. Recent work of Zähner[2] on the detection and estimation of fusaric acid by chromatographic and bioassay techniques suggests the possibility of detection of fusaric acid *in vivo* in wilting host plants. We have been employing various chromatographic techniques, particularly the circular macro-[3] and micro-[4] techniques developed by one of us, for the detection and quantitative estimation of fusaric acid, and experienced considerable difficulty in obtaining sharp demarcation of the bands and reproducible $R_F$ values to facilitate quantitative estimation. Fusaric acid detected with brom cresol green indicator gives a diffused and ill-defined yellow band in a blue background, possibly due to the poor ionization of the acid. The difficulty was overcome by preliminary conversion of fusaric acid into its copper complex on the filter paper with copper sulphate and irrigating the complex with excess copper with *n*-butanol/acetic acid/water (4 : 1 : 5). The quantitative estimation of fusaric acid has been carried out with this technique based on the area method and will be published shortly; we have used the technique for the detection of fusaric acid *in vivo* in wilted cotton plants.

Cotton plants (Karunganni 2, *Gossypium arboreum*) susceptible to *Fusarium* wilt were grown in pots containing 500 gm. of sterilized garden soil mixed with 10 per cent soil-oat inoculum of *Fusarium vasinfectum* Atk. Visible symptoms of wilt were noted after ten days. The roots, shoots and leaves from wilted plants were collected, washed thoroughly with sterile distilled water and the sap squeezed out by maceration, and about 0·75 μl. of the clear sap spotted on circular filter paper (Whatman No. 1, 7·4 cm.) followed by copper sulphate (4 μgm./0·75 μl.). The paper was dried and irrigated with the solvent according to the technique reported earlier[3]. At the end of the period of irrigation the papers were dried and sprayed with 0·05 per cent rubeanic acid in acetone. The fusaric acid-copper complex and excess copper appeared as sharp green bands and were intensified by exposure to ammonia vapour as described elsewhere[4]. $R_F$ values were computed on the microscope. Table 1 gives the $R_F$ values of copper and the copper-fusaric acid complex in controls and in saps of roots, shoots and leaves of wilting cotton plants in the three typical solvent mixtures *n*-butanol/formic acid/water (5 : 3·5 : 5), *n*-butanol/acetic acid/water (4 : 1 : 5) and *n*-butanol/acetic acid/water (3·5 : 1·5 : 5), indicating the presence of fusaric acid *in vivo*. Chromatograms of saps of healthy cotton plants under similar conditions did not show the copper-fusaric acid complex bands. The results were confirmed with six more solvent mixtures to establish conclusively the presence of the toxin *in vivo*. The consistent presence of the complex bands in chromatograms of diseased sap in the positions corresponding to those of the copper-fusaric acid controls in every case would eliminate the possibility of interference by other metabolites which might also form complexes with copper.

Work on the quantitative aspects with resistant and susceptible varieties of cotton is under way and will be reported elsewhere.

Table 1

| Material spotted | $R_F$-values<br>*n*-Butanol/formic acid/water (5 : 3 5 : 5) | <br>*n*-Butanol/acetic acid/water (4 : 1 : 5) | <br>*n*-Butanol/acetic acid/water (3·5 : 1 5 : 5) |
|---|---|---|---|
| 1 Copper | 0 157 | 0 494 | 0·666 |
| 2 Copper-fusaric acid complex | 0 088 | 0·273 | 0·617 |
| 3 Diseased root sap | 0·086 | 0·266 | 0·610 |

# Nerve Endings as Transducers of Thermal Stimuli in Lower Vertebrates

It is now generally accepted[1] that the changes in impulse frequency in a sensory nerve are the result of processes which alter the state of polarization of the nerve membrane in the sense organ. In thermoreceptors, and especially in those[2] in which the response to cooling is an increase in the frequency of discharge, the mechanism whereby the change of temperature can cause a change in membrane polarization remains unknown.

The existence of this change of polarization is suggested by the following experiment on the ampullæ of Lorenzini of *Raja*. By passing a weak direct current between the sensory nerve and the outside of the capsule surrounding the sense organs, it is possible to alter the membrane polarization of the nerve endings and thereby the frequency of the spontaneous discharge (cf. ref. 3); the relationship between the strength of the applied current and the change in the spontaneous frequency is linear. If a standardized sequence of temperature changes is applied while a constant current is passing (Fig. 1), the responses to the thermal stimuli are added quantitatively to the responses to the electrical stimuli. The thermal response (in terms of the change in the number of impulses per second) remains the same whatever the level of the spontaneous frequency at the start of the sequence. This suggests that the temperature change is acting on the mechanism of the repetitive discharge at the same point as the electrical polarization. A similar experiment on the lateralis organs of *Xenopus laevis* is shown in Fig. 2 (the response of the lateralis organs of *Xenopus* to temperature change is similar to that of the ampullæ of Lorenzini, although considerably less sensitive).

Tyrrell, Taylor and Williams[4] suggest that the spontaneous discharge from the ampullæ is due to the existence of non-isothermal conditions. From experiments with *in situ* and isolated preparations, it can be stated that the discharge continues even when the whole preparation is at the same temperature; the same is true of the spontaneous discharge from the lateralis organs of *Xenopus*. Moreover, in both these sense organs the response to temperature

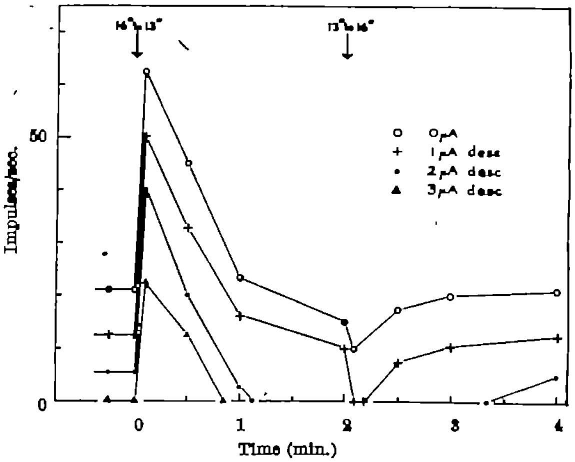

Fig. 1. Discharge frequencies in a single sensory unit from an ampulla of Lorenzini of *Raja clavata* showing the effect of a rise and fall of 3 deg. C. at four different current strengths (a descending current flows from sense organ to nerve, and an ascending from nerve to sense organ)

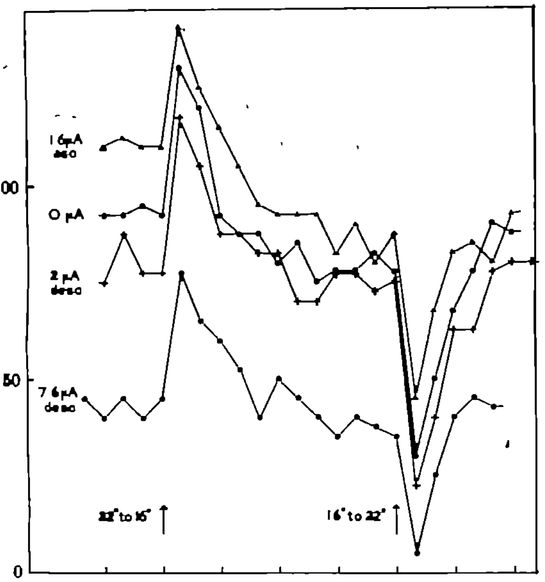

Fig. 2. Discharge frequencies in a multifibre preparation of lateralis organs of *Xenopus laevis* showing the effect of a rise and fall of 6 deg. C. at four different current strengths

hange is the same irrespective of the direction of he spatial temperature gradient. They therefore gree in this respect with the cold receptors of the at's tongue[5], and give no support to the spatial gradient theory of Lele, Weddell and Williams[6].

## Long-term Transplants of Infantile Rat Pituitaries cultivated *in vitro* and grafted into the Anterior Eye Chamber of Young Cats

IN a previous communication in *Nature*[1], we have reported that successful grafts of the anterior rat pituitary have been obtained when glands cultivated *in vitro* were transplanted into the anterior eye chamber of very young cats. Following the same line of work, we have transplanted rat ovaries and testes, both normal and cultivated *in vitro*, under the kidney capsule of adult cats and observed a phenomenon which, so far as we know, has not been recorded in biological literature. A few days following the transplantation, at the site of grafting a 'tumour' was formed which when sectioned and stained was found to be composed almost exclusively of lymphocytes that had migrated into this region. Remnants of the grafted tissue, surrounded by lymphocytes, were also present, some in advanced stages of degeneration.

Further studies on the tumour tissue revealed a gradual process of organization suggesting lymphoid tissue normally scattered along the intestinal tract, with typical nodules composed of a central medulla and a peripheral cortex (Fig. 1). Some of these tumours of healthy tissue grew to the size of a pea. In some experiments as many as seven or eight nodules have been counted per section of the tumour tissue. The newly organized lympho-blastema persisted in the kidney long after the grafted tissue was destroyed (in the eye of the cat for four months and probably longer). If, however, cat ovaries or testes were transplanted under the kidney capsule of the rat, organized lymphoid tissue was not formed, although the number of transplants was not sufficient to warrant a definite conclusion. It appears that in the cat it is only living tissue that is capable of inducing the formation of organized lymphoid tissue at the site of transplantation, for spruce-wood splinters, knots of silk thread, boiled egg albumen and glass beads when placed under the kidney capsule, in repeated experiments, failed to produce this effect.

When the types of cells in the tissue found at the site of transplantation of some of the rat pituitaries in the eye of the cat were subjected to closer examination, it was found that they were comparable in every detail with the medullary portion of the lymphoid nodule developed at the site of transplantation of the rat gonad in the kidney of the cat. Hence we conclude that the graft-induced medullary portion of a lymph nodule in the eye of the cat was mistaken by us for the grafted pituitary tissue itself (Figs. 2 and 3 in our earlier communication).

We wish to make it clear, however, that we have definite evidence that some of the grafted explants of the rat pituitary survived for at least two months; the normal transplants did not survive (see Fig. 1 in the earlier communication). These persistent hetero-transplants, so far as we can tell, although intimately bound to the iris tissue of the host by fibrous connexions, were not vascularized, an observation which is in agreement with the findings of Merwin and Hill[2] on intraspecific grafts of normal tissue in mice. Further research has been undertaken in order to ascertain if non-vascularized hetero-transplants, similar to the homo-transplants reported by Merwin and Hill, survive for still longer periods.

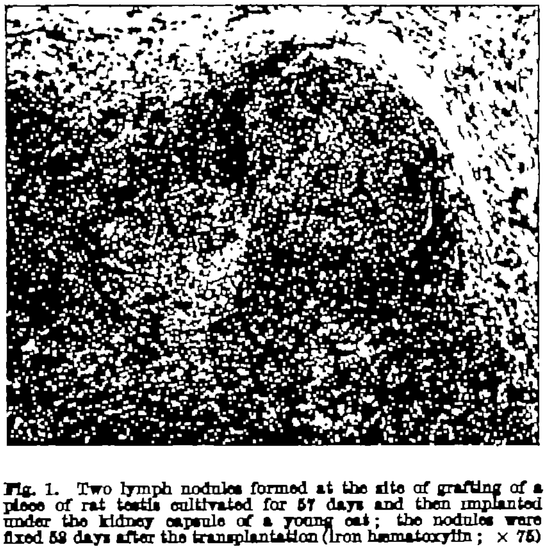

Fig. 1. Two lymph nodules formed at the site of grafting of a piece of rat testis cultivated for 57 days and then implanted under the kidney capsule of a young cat; the nodules were fixed 53 days after the transplantation (Iron hæmatoxylin; × 75)

In the face of evidence presented above, it is clear that our suggestion that embryo extract may have a protective action upon cultivated tissue following its transplantation into hosts belonging to a different species, will require further study, especially of the vascularized grafts. There is no doubt that the transplants previously cultivated *in vitro* behave differently from normal grafts; they establish circulation at a much later date than the latter, and, as a consequence, they survive longer.

## Colicine *K*

Colicines are substances of unknown nature which are elaborated by certain strains of Enterobacteriaceae and which have the ability to kill other strains within this group. At the time of their discovery some thirty years ago[1], it was apparent that colicines bore a similarity to the bacteriophages, yet differed in that they could not be transmitted by serial passage. In recent years considerable attention has been paid these agents[2], largely because of this relationship and because of a renewed interest in the bacteriophages themselves. The brilliant investigations of Fredericq have revealed that there are many different colicines; some seventeen specific types have thus far been described[3]. Furthermore, these agents are now known to be elaborated by micro-organisms other than those of the enteric group. Because of this, the name 'bacteriocines' has been suggested to designate them[4].

The similarities between phages and colicines are striking. Thus, Fredericq[5] has demonstrated that colicine-susceptible micro-organisms yield resistant variants which are also resistant to certain phages, and vice versa. In addition, it has been shown that those chemical and physical agents which induce the release of phage from lysogenic bacilli can, in certain instances, also bring about liberation of colicine from colicinogenic micro-organisms[6]. Because of these seemingly intimate relationships, the implication has been made that colicines might be precursors of phages[7]. If this be true, one would expect these agents to bear some immunological relationship to one another. Yet it has not been possible to show, in the case of colicine *K*, that biological activity can be neutralized by an antiserum to the colidysentery phage *T6*, the virus to which this colicine is presumably related[8]. The affirmations which have appeared from time to time concerning the protein-like nature of colicines[1,9] are in reality not fully substantiated. These substances have never been isolated in purified form and hence their chemical status remains obscure.

Several years ago an attempt was initiated in this laboratory to isolate and characterize colicine *K*, to study its chemical and immunological properties and to relate these to phage *T6*. The following is an account of the present state of this investigation.

A strain of *E. coli* producing colicine *K* designated as *K235* was kindly supplied by Dr. Pierre Fredericq. When these micro-organisms were plated on proteose-peptone or nutrient agar, they yielded colonies which appeared to be morphologically uniform. On neopeptone agar, however, two distinct colonial forms were observed; one was transparent and slightly rough, the other smooth, mucoid and opaque. In liquid media the latter elaborated five times as much colicine as the former.

The opaque variant was grown in 15 l. of a medium consisting of 1 per cent 'Difco' casamino-acids, 1·5 per cent glucose, 0·5 per cent dialysed 'Difco' yeast extract, 18 gm. of $Na_2HPO_4$ and 7·5 gm. of $KH_2PO_4$. It was essential for the production of maximal amounts of colicine that the *p*H of the medium be maintained precisely at 7·0. This was achieved with the aid of an electronic device[10]. When bacterial growth had ceased ($2 \times 10^{10}$ B/ml.) the bacilli were killed with chloroform and separated by centrifugation. The supernate containing the colicine was rapidly concentrated *in vacuo*, and, after thorough dialysis, crude colicine *K* was obtained by freeze-drying the residue. This material (5·0 gm.) contained several components when examined in the Tiselius apparatus. Purification was accomplished by fractional precipitation with ethanol (75 per cent) at 0° followed by repeated precipitation with ammonium sulphate (75 per cent) at *p*H 4·5, and dialysis. An aqueous solution of this material, which still contained two electrophoretically different components, was then shaken with chloroform-octyl alcohol. The colicine fraction formed an emulsion with the organic solvent which was separated by centrifugation. The inert fraction remained in the supernate. The colicine (1·0 gm.) was recovered from the chloroform emulsion by precipitation with ten volumes of ethanol at 0° C.

Purified colicine *K* obtained in this manner is water-soluble, colourless and free of nucleic acid. It contains 6·5 per cent of nitrogen and 1·6 per cent of phosphorus. In the Tiselius apparatus it appears to show but one electrophoretic component when examined at various *p*H values. In the ultracentrifuge, however, solutions are heterodispersed. The material appears to be a macromolecular substance constituted from carbohydrate, protein and lipid. It is toxic both in mice and rabbits and has potent antibacterial properties as well. 0·02 ml. of a solution containing 1·0 γ/ml., when placed on the surface of nutrient agar contained in a Petri dish and seeded with $5 \times 10^7$ *E. coli* b. cells, inhibits completely the growth of the bacilli encompassed by the area of the droplet. Colicine *K* is thermostable; its activity is unimpaired by heating a neutral aqueous solution for 10 minutes at 100° C. Such solutions are also stable at room temperature between *p*H 3·0 and 9·5. Activity is rapidly destroyed, however, by treating a solution at *p*H 8·0 with crystalline trypsin, or chymotrypsin, and by contact with 1 per cent formalin. Colicine *K* is a potent antigen. It elicits antibodies in rabbits which specifically precipitate the colicine, neutralize its antibacterial activity, and agglutinate the organisms from which the colicine was derived. In neutralization tests colicine *K* antisera do not cross-react with phage *T6*, however, nor do *T6* antisera precipitate or neutralize the colicine. Although *T6* resistant variants of Phase II *Sh. Sonnei* exhibit resistance to colicine *K* and vice versa, this does not appear to be sufficient reason for believing that these two agents are otherwise related. The results of this study have revealed that phage *T6* and colicine *K* have neither chemical nor immunological properties in common.

The chemical, physical, immunological and toxic properties of the substance obtained from the culture medium in which *E. coli K235* is grown indicate that the material having colicine *K* activity is the somatic or *O* antigen of the bacillus. The fact that this complex has potent antibiotic properties seems at first sight extraordinary. Yet it should not be forgotten that *O* antigens of Gram-negative bacilli exert potent toxic effects upon certain mammalian species. It is not inconceivable, therefore, that they might exert a similar effect upon an occasional bacterial species.

It cannot yet be said with complete certainty, however, that colicine activity is an inherent property of the *O* antigen of *E. coli K235*. It is possible that colicine *K* is in reality a distinct molecular species bound to the lipocarbohydrate protein complex. If this is the case, the union is firm, and has until now defied attempts at dissociation. From the evidence at hand, however, we are at the moment inclined to favour the first point of view.

## Anti-acetylcholine and Anti-histamine Actions of the Total Alkaloids of *Rauwolfia serpentina* Benth

Dasgupta, Ray, Roy and Werner[1], Mukherjee[2] and the present authors[3] have made certain observations on the anti-adrenaline effect of extracts of *Rauwolfia serpentina*, but their effects on the action of acetylcholine or of histamine have not yet been reported. Experiments have been carried out on isolated strips of guinea pig ileum in Dale's bath, containing oxygenated Ringer–Locke's solution at 35° C., and the modifications caused by varying concentrations ($10^{-6}$ to $10^{-4}$ gm./ml.) of extracts of *Rauwolfia serpentina* (total alkaloids extracted in 2 per cent hydrochloric acid) on the action of acetylcholine ($10^{-8}$ gm./ml.) or of histamine ($10^{-8}$ to $10^{-7}$ gm./ml.) were studied. The extracts produced, by themselves, a definite but slight and transient contraction of the intestine. Dasgupta *et al.*[1] did not, however, find any stimulating effect on intestine *in situ*, whereas Chopra, Gupta and Mukherjee[4] mention a stimulating property of the extract on such a preparation. (Dr. R. P. Banerjee, of the Indian Council for Medical Research, prepared extracts of *Rauwolfia serpentina* in three different concentrations of hydrochloric acid (namely, 2, 5 and 10 per cent) with the view of fractionating the different active principles. The results obtained with an extract in 2 per cent hydrochloric acid are described here; those with 5 and 10 per cent acid extracts are under investigation.)

*Anti-acetylcholine action.* In all of the twelve experiments carried out, there was a greater degree of inhibition of the action of acetylcholine in the presence of the higher concentration of the extract of *Rauwolfia* in the bath, when the former was applied 30–50 sec. after the administration of the extract to the bath fluid. A concentration of the extract of 5 × $10^{-5}$ gm./ml. and stronger completely annulled the effect of $10^{-8}$ gm./ml. acetylcholine.

*Anti-histaminic action.* The results with histamine applied 30–50 sec. after *Rauwolfia* extract were similar to those with acetylcholine mentioned above. The extract of *Rauwolfia* in concentrations of 5 × $10^{-5}$ gm./ml. and stronger inhibited the action of histamine ($10^{-8}$ or 5 × $10^{-8}$ gm./ml.). A stage of slight potentiation of the action of both acetylcholine and histamine was noted in a few cases during the phase of recovery of the action of acetylcholine and histamine on repeated changing of the bath fluid, after an earlier observation of the action in the presence of *Rauwolfia* extract.

## 'Kernechtrot' or Nuclear Fast Red in the Histochemical Detection of Calcareous Corpuscles in *Taenia saginata*

*Taenia saginata*, like many other cestodes[1], is known to contain numerous calcareous corpuscles or calcium balls distributed throughout the parenchyma. These corpuscles, in addition to their calcium content, consist of an organic base, containing[2] deoxyribo- and ribo-nucleic acids, simple proteins, glycogen and a hyaluronic acid-type of polysaccharide. With Gomori's modified technique these corpuscles also gave a positive reaction for alkaline phosphatase. The presence of calcium in these balls was indicated by von Kossa's silver test for calcium[3].

McGee-Russell[4] has recently reported the selective affinity of 'Kernechtrot' or nuclear fast red (batch 3569) for soluble inorganic calcium salts and its use in the histochemical detection of calcium.

We have tried to confirm the specificity of this dye by using the proglottids of *T. saginata* with their calcium-containing corpuscles as test material. It has been observed that the dye stains these corpuscles, and in some cases their immediate neighbourhood, brilliant red (see Fig. 1). As an experimental control we have stained in a similar manner identical sections of the same tissues after previous treatment with citrate buffer (*p*H 4·5–5) to remove calcium. The corpuscles failed to take up the dye in this case. This observation therefore confirms the conclusion regarding specificity of the dye for detecting calcium in the tissues. A detailed account of this work will be published elsewhere.

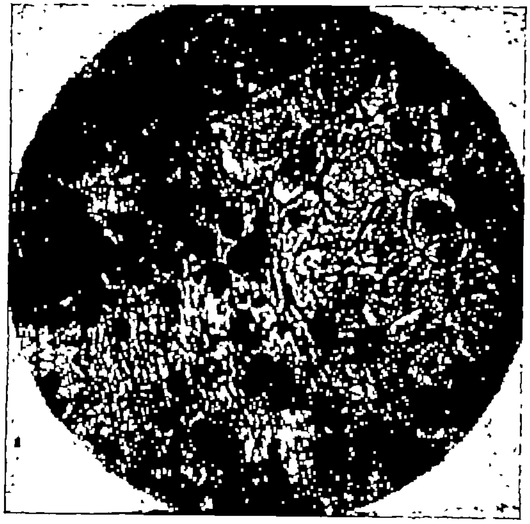

Fig. 1. Photomicrograph of part of a section of a proglottid of *Taenia saginata* showing the calcareous corpuscles stained with nuclear fast red. × 160

Our thanks are due to Messrs. George T. Gurr, Ltd., London, for supplying us with a sample of nuclear fast red for our investigations.

## Inhibition Steps in Sulphonamide Bacteriostasis

The activity of several compounds, structurally unrelated to *p*-aminobenzoic acid, in reversing growth inhibition of *Escherichia coli* by sulphonamides, was explained by Shive and Roberts[1] as due to their being products of enzymes associated with *p*-aminobenzoic acid. Using increasing concentrations of sulphanilamide, these authors showed that it inhibits sequentially the synthesis of methionine and xanthine by the organism. Winkler and de Haan[2] extended this study to higher concentrations of the inhibitor, and reported further involvement of serine and thymine (the latter, interchangeably with pteroyl glutamic acid) in that order in the *p*-aminobenzoic acid action; further addition of valine was stimulatory to growth.

During studies on the reversal of growth inhibition of *Esch. coli* (McLeod) by sulphadiazine, we observed that, in a concentration of the drug up to 30 mgm. per cent, a combination of the foregoing five metabolites was necessary and effective; however, at its maximum solubility (50 mgm. per cent) in the medium employed[3] they could no longer overcome growth inhibition. When, in addition to them, mixtures of purines and pyrimidines, amino-acids, or the *B*-group of vitamins were tried (see Table 1), it was found that the amino-acid mixture, and to a less extent the vitamins, could reverse considerably the inhibition of growth by the drug. Using individual amino-acids, it was ascertained that the active member was either glycine or threonine; the former was more effective than the latter on a molar basis, and there was no additive effect among the two. Vitamin $B_{12}$ alone, among the B vitamins, showed a reversal effect. A combination of glycine and vitamin $B_{12}$ was nearly as active as *p*-aminobenzoic acid, and substitution of xanthine by a mixture of purines (xanthine, adenine and guanine) gave reversal of growth inhibition comparable to that with *p*-aminobenzoic acid (Table 1).

Table 1. Reversal Effects on Growth Inhibition of *Esch. co*
by Sulphadiazine

| Additions to 10 c.c. of basal medium[a] | Growth[b] without sulphadiazine | Growth[b] with sulphadiazine (5 mgm./10 c.c.) |
|---|---|---|
| 1 None | 47 | 0 |
| 2 *p*-Aminobenzoic acid (0·5 mgm.) | 47 | 46 |
| 3 Methionine (0·5 mgm.) + xanthine (0·25 mgm.) + serine (0·2 mgm.) + thymine (0·25 mgm.) + valine (0·5 mgm.) | 40 | 0 |
| 4 As in (3) + amino-acid mixture[c] | 72 | 53 |
| 5 As in (3) + vitamin mixture[d] | 46 | 25 |
| 6 As in (3) + purine-pyrimidine mixture[e] | 48 | 0 |
| 7 As in (3) + glycine (0·25 mgm.) | 48 | 27 |
| 8 As in (3) + threonine (0·4 mgm.) | 47 | 19 |
| 9 As in (7) + threonine (0·4 mgm.) | 48 | 28 |
| 10 As in (3) + vitamin $B_{12}$ (10 mμgm.) | 40 | 22 |
| 11 As in (7) + vitamin $B_{12}$ (10 mμgm.) | 47 | 40 |
| 12 As in (11), but with 0·1 mgm. each of adenine, xanthine and guanine in place of 0·25 mgm. of xanthine | 50 | 48 |

[a] Green and Sevag (ref. 3).

[b] Represents 48 hr. growth in terms of turbidity measured on Klett-Summerson photocolorimeter at 660 mμ.

[c] 0·2 mgm. each of alanine, arginine, asparagine, aspartic acid cysteine, glutamic acid, glycine, histidine, isoleucine, leucine, lysine phenyl alanine, proline, threonine, tryptophan and tyrosine.
In all experiments, racemic forms of the optically active amino acids were used.

[d] Thiamine hydrochloride, riboflavin, nicotinic acid, pantothen acid, and pyridoxine hydrochloride (10 μgm. each), pteroyl glutami acid (3 μgm.), 'Leucovorin', Lederle (3 μgm.) and vitamin $B_{12}$ (10 mμgm.).

[e] 0·1 mgm. each of adenine, guanine and uracil.

It would seem from the above that synthesis of glycine is yet another reaction mediated by *p*-aminobenzoic acid and blocked by sulphonamides. The organism *Esch. coli* is apparently capable of converting threonine to glycine (cf. ref. 4). Such a possibility is also indicated from the observation of Ravel *et al.*[5] that glycine and threonine both increase synthesis of 4-amino-5-imidazole carboxamide by *Esch. coli* under conditions of sulphonamide bacteriostasis.

It is difficult to explain the relationship observed here between the action of *p*-aminobenzoic acid and that of vitamin $B_{12}$ solely on the basis of an effect of the former on the synthesis of the latter[6]. Shive[6,7] had also reported on the potentiating action of vitamin $B_{12}$ on methionine, xanthine and serine, at each stage in their reversal of sulphanilamide action, and on the replaceability of thymine by pteroyl glutamic acid or by vitamin $B_{12}$.

## Density Inversions in Canadian Eastern Arctic Waters

AMONG the hydrographic results of the *Calanus* expeditions of 1949–51 in Ungava Bay, Hudson Strait and Frobisher Bay, sponsored by the Fisheries Research Board of Canada, are twenty-two instances of density inversion showing unstable conditions in the sea. They were observed at twenty stations (two stations showing inversion at two different depths) out of a total of forty-eight stations occupied during the three seasons. Six of the inversion stations were in Ungava Bay, one in the Button Islands north of Cape Chidley, four in Hudson Strait between Wakeham Bay and Lake Harbour, and the remainder in Frobisher Bay.

Such instabilities, appearing in oceanographic results in the past, have usually been looked upon as fictitious, and attributed to errors in thermometer readings, sample labelling, titration or filing of results. In the present instance, titrations have been repeated where possible, and the methods used on board ship seem to preclude the possibility of other errors. Recently, Spilhaus *et al.*[1] have recorded similar inversions in the waters just south of Cape Cod, and have given evidence of some correlation of the times of observed instability with the times of lunar transit. I am informed by Dr. Carsola (personal communication) that inversions of short duration are common in shallow-water observations in progress at the U.S. Navy Electronics Laboratory at San Diego, and Dr. John Tait, of Aberdeen, has reported (at the 1952 meeting of the *Conseil Permanent* in Copenhagen) some more or less persistent instabilities observed during work in the Faero-Shetland Channel. There is a published record of another example, in the Okhotsk Sea, from the nineteenth century[2], and the *Michael Sars* expedition of 1910 found a density inversion at one station in the Atlantic (28° 37′ N.; 19° 08′ W.)[3].

The *Calanus* observations have been related to the state of the tide in each instance and are plotted on a tidal clock in Fig. 1. Tests ($\chi^2$) comparing the radial scatter of the stations with inversions, those without, and of all stations, respectively, with an equally distributed radial pattern, give the $P$ values shown. The latter two observed distributions are reasonably close to a random scatter, as would be expected; but the distribution of the instabilities verges on disagreement with random scatter, and the $P$ value for the comparison of the means (standard error of the difference of the means) of the inversion and non-inversion stations is on the margin of significant disassociation (difference is 2·02 times its standard error). It is, moreover, at once apparent on examination that, of the twenty inversion stations, half lie in one quadrant, in the first three hours of the ebb tide.

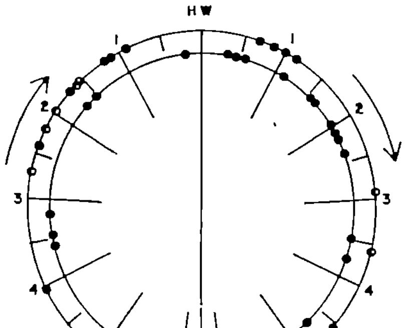

Fig. 1. A twelve ½-hour tidal clock, showing the times, with respect to tide, at which stations with density inversions (black circles) and without density inversions (open circles) were occupied. The $P$ values are explained in the text: ●, $P = 0·065$; ○, $P = 0·345$; ● + ○, $P = 0·565$; $S.E._d$, $P = 0·055$

The establishment of these unstable conditions, even for the short periods of time during which they probably exist, obviously requires considerable forces, which are apparently to be found in the extreme tidal movements of the area. Hudson Strait tides are very high (33 ft. at Ashe Inlet), the mean spring tide interval at Frobisher Bay is 32¼ ft., and a tide of more than 50 ft. has recently been recorded at the head of Ungava Bay.

The details of this work will appear in full in due course.

## Temperature-Ranges and Distributions of some Vascular Plants

ATTEMPTS to fit isotherms to certain limits of areas of plant distributions have sometimes been successful; but, for example, in the discussion of the areas given in the Biological Flora of the British Isles, only rarely is an isotherm limit shown. A July isotherm is given as an upper temperature limit for *Lobelia dortmanna*[1], and a July or August isotherm as a lower limit for *Halimione portulacoides*[2], and a January isotherm as a lower limit for *Arbutus unedo*[3]; and in addition to these and some other examples in the literature, I notice that the January (actual) isotherm 35° F. gives an approximate fit for the southern limit[4] of *Andromeda polifolia*. The fact of a broad coincidence between an isotherm and a limit of a distribution does not prove a relationship, but nevertheless a reasonable fit has usually been taken as indicating that temperature may probably be the limiting factor.

A limit of winter cold will obviously operate on a plant in a different way from a limit of July heat; and four possible sorts of temperature limits have been quoted above for particular cases. It could be supposed that for each plant species there may be, in broad terms, an optimum summer temperature, with upper and lower limits (beyond which the species is either damaged or else is at a disadvantage in competition with other species better adapted to the particular temperature-levels), and an optimum winter temperature, with upper and lower limits. Winter limits might be expected to operate most typically at the month of lowest temperature (as an approximation, January in the northern hemisphere); and although July might not always be the most operative summer month, in long-term means, deviations of adjacent months would at least be approximate functions of July deviations.

It does not, however, seem to have been generally realized how frequently plant areas can be represented by a combination of upper and lower limits respectively both for January and July (with January and July limits transposed for the southern hemisphere). The envelopes of the distributions I have used in Figs. 1 and 2 are of the same form as that referred to in a recent communication[5] as governing the world distribution of acarine disease of bees, and the general formula for the envelope is:

$$(\gamma_2 - \gamma_1)^2(2\alpha - \alpha_1 - \alpha_2)^2 + (\alpha_2 - \alpha_1)^2(2\gamma - \gamma_1 - \gamma_2)^2 = (\gamma_2 - \gamma_1)^2(\alpha_2 - \alpha_1)^2$$

where $\alpha$, $\alpha_1$, $\alpha_2$ are respectively January actual temperature and lower and upper limits of the temperature, and $\gamma$, $\gamma_1$, $\gamma_2$ are July actual temperature and lower and upper limits.

Forty-one distributions have so far been plotted, including the twenty areas given in Prof. J. R. Matthews's recent book[4], seven from the Biological Flora of the British Isles[6], and fourteen from other sources, reproduced by Cain[7] and Zander[8]. In this material, thirty gave really useful approximations to the given distributions, whereas in ten there were discrepancies which seemed of greater importance, and in one (*Lloydia serotina*) the fit was not satisfactory with the approximate and not very detailed isotherms which have so far been used. This is possibly due to the fact that these isotherms may not accurately represent the temperatures of the mostly isolated mountain sites where this species is found. There have been indications that the difficulty may be rather general with such species. Some of the other anomalies so far encountered seem to be partly explainable in terms of major rainfall differences between different parts of the areas.

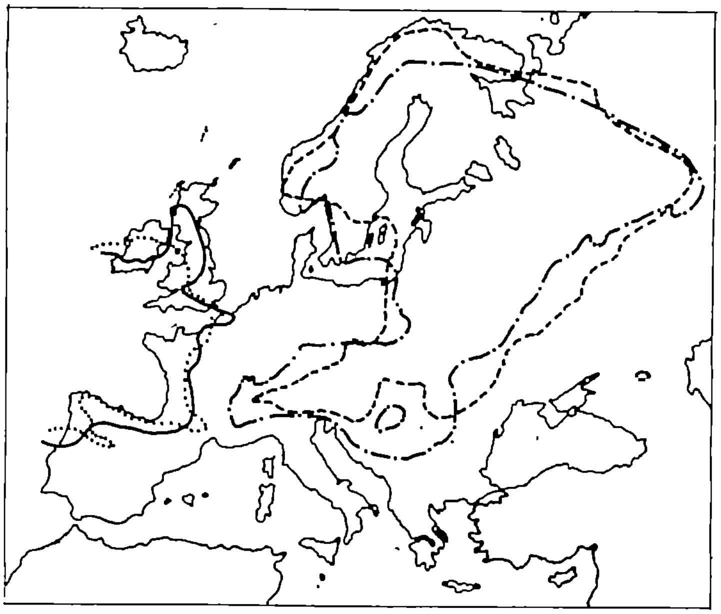

Fig. 2. *Ranunculus lenormandi.* ———, Distribution from Matthews, ref. 4, p. 130 (after Salisbury); ·······, approximate curve for $\alpha_1 = 38°$ F., $\alpha_2 = 48°$ F., $\gamma_1 = 58°$ F., $\gamma_2 = 68°$ F.
*Picea excelsa.* —·—·—, Distribution from Zander, ref. 8, p. 41 (after Hueck); - - - - -, approximate curve for $\alpha_1 = 2°$ F., $\alpha_2 = 30°$ F., $\gamma_1 = 52°$ F., $\gamma_2 = 69°$ F.

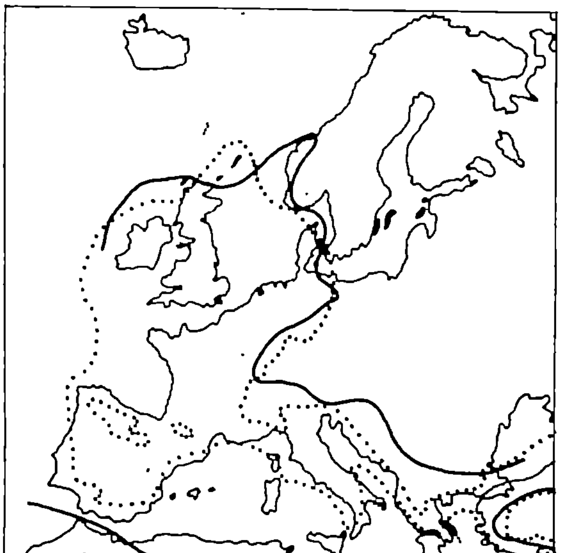

Fig. 1. *Ilex aquifolium.* ———, Distribution from Matthews, ref. 4, p. 128 (after Oltmanns); ······, approximate curve for $\alpha_1 = 30°$ F., $\alpha_2 = 44°$ F., $\gamma_1 = 54°$ F., $\gamma_2 = 86°$ F.

The more accurate plotting of these areas is now in hand, and further maps will in due course be published elsewhere.

It may be noted that this distribution is closely similar to, and in certain cases identical with, that obtained by a formula of the same form embodying a range of annual mean temperature and a range of January–July temperature differences. It can also be shown that, for the world as a whole, annual temperature-range is an approximate function of the annual precipitation ($P$), and if there had been an exact relationship between these quantities it would have followed that similar areas could have been obtained by a formula of the same sort embodying a range of annual mean temperature and a range of the function of $P$. This would have corresponded approximately with the usually accepted idea of temperature bands modified by different levels of humidity. Interesting and sometimes useful areas can be obtained in this way, but they have not generally proved so close as those obtained from temperatures alone.

I wish to thank Prof. J. R. Matthews for his interest in this work, and Dr. G. D. Morison and Prof. V. C. Wynne-Edwards for help in connexion with the literature, also Dr. D. J. Finney for mathematical advice.

## Effect of Indian Ink on *Plasmodium berghei* Infections in Mice

INJECTIONS of indian ink, causing so-called 'blockade' of the reticulo-endothelial system, have, in the past, been classified with splenectomy and cortisone as agents calculated to lower the resistance of host animals to plasmodial infections. For example, Trager[1], working with chickens infected with *Plasmodium lophurae*, found that indian ink usually caused the development of heavy parasitæmias in the birds receiving it.

Recently, I have found[2] that cortisone does not produce higher parasitæmias in mice or hamsters infected with *P. berghei*, and this has been confirmed by Singer, who has also shown that this is equally true of splenectomy[3]. I have now found that indian ink has a strongly inhibitory effect on infections with this *Plasmodium*.

Mice were injected intraperitoneally with 0·2 ml. of a commercial indian ink, diluted with the same amount of physiological saline. This large dose was well tolerated, and was followed next day by intraperitoneal inoculation with infected citrated hamster blood. A similar number of control mice received saline followed by infected blood. Blood films were made daily and were stained with Giemsa.

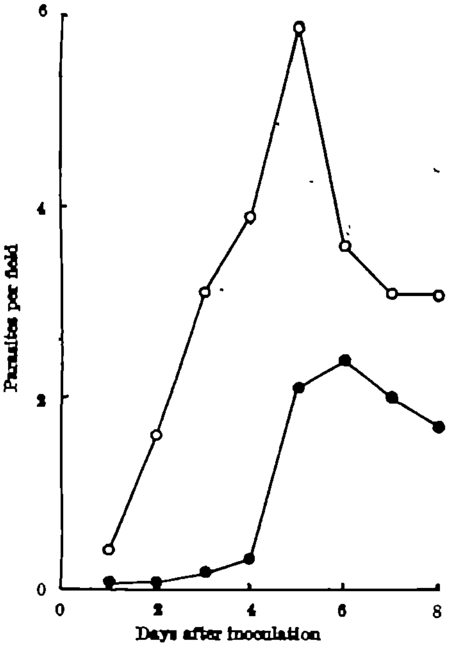

Fig. 1. Parasitæmia in mice treated with indian ink and infected with *P. berghei*. ○—○—, Average of five control mice; ●—●—, infection in one mouse, *M* 35, treated with indian ink

Of five mice treated with indian ink, one died on the day following infection, and of the others, three showed only occasional parasites throughout the eight days that the experiment lasted, while the fifth mouse had a very low parasitæmia. The infection proceeded normally in the control mice. For two or three days after the ink injections there were many polymorphonuclear leucocytes in the peripheral blood, but these soon fell to a normal level. Seven or eight days after infection, the experimental animals showed a considerable degree of anæmia, with greatly increased numbers of reticulocytes in the peripheral blood, but parasites were very rare.

Indian ink greatly stimulated the production of immature red cells, apart from its effect on the macrophages. In this experiment, the one mouse that had a low-grade parasitæmia had many reticulocytes in the peripheral blood—supposedly the preferred substrate for parasite growth—after several days, yet no great increase in parasitæmia occurred. Further investigations are needed before any definite conclusions can be drawn.

## An Uncollected Record of the Great Sea-serpent

COMPILATIONS and bibliographies are double-edged weapons; though they facilitate access to some sources of information, they usually tend to intensify the concealment of others. Some two hundred reports of the sea-serpent have been collected and analysed in the works of Oudemans[1] and of Gould[2]; but the record which follows has so far escaped scientific notice. Though trivial by itself, it corroborates a number of more detailed accounts of a similar monster in the North Atlantic towards the end of the eighteenth century.

Thomas Holcroft[3] (1745–1809), in a letter written in 1799, describes an interview on board the *Kennet* (Captain Thompson). After recounting two second-hand stories of the Kraken and comparing these with Pontoppidan's versions, Holcroft continues:

"Finding this Leviathan so familiar to their belief, I next inquired if they had heard, or knew any thing of the sea-snake, by some called the sea-worm? To this question I received a still more direct answer. The Mate, Mr. Baird, who certainly was not a liar by habit, whatever mistake or credulity might make him, assured me that, about midway in a voyage to America, in the Atlantic, he had himself seen a fish, comparatively small in the body, of from forty to fifty fathoms in length; and that it had excited great terror in the Captain, who was well acquainted with those latitudes, lest it should sink the ship.

". . . and I think it a duty to collect evidence, and to remain on this question, as on many another, in a certain degree of scepticism."

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, October 10

King's College, London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr. Gabriel Kron: "Tensor Analysis of Rotating Electrical Machinery". (Further Lectures on October 11, 12, 13 and 14.)

University of London (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. F. Safar (Baghdad): "Hatra—the City and its Inscriptions". (Further Lectures on October 12 and 14.)*

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. F. Danielli: "Physico-Chemical Mechanisms of Drug Action".*

University of London (in the Geology Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. B. Gutenberg (U.S.A.): "Low Velocity Layers". (Further Lecture on October 14.)*

## Tuesday, October 11

Zoological Society of London (in the Mappin Refreshment Pavilion, Mappin Terrace, Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

University of London (in the Hall of the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5.30 p.m.—Dr. R. P. Linstead: "The Future of the Imperial College".

Society of Chemical Industry, Plastics and Polymer Group (in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Discussion on "Physical Properties and Testing of Polymers".

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 8.15 p.m.—Prof. V. G. Childe: "The Culture Sequence in Prehistoric Thrace". (First of two Lectures on "New Archæological Discoveries in Bulgaria". Further Lecture on October 18.)*

## Wednesday, October 12

University of London, School of Pharmacy (in the Beveridge Hall, Senate House, London, W.C.1), at 3 p.m.—Sir Ian Heilbron, F.R.S.: "The Chemist and Pharmacist on a Common Front" (Inaugural Address at the Opening of the 114th Session of the School of Pharmacy).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Beno Gutenberg (U.S.A.): "The Energy of Earthquakes" (Eleventh William Smith Lecture).

Society of Chemical Industry, Corrosion Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Mr. F. A. Champion and Mr. G. W. Walkiden: "The Composition of Sprayed Aluminium Coatings"; Mr. T. P. Hoar: "Sprayed Alloy Coatings".

Society of Chemical Industry, Food Group (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Meeting on "Factors Affecting the Choice of Food".

## Wednesday, October 12—Friday, October 14

Iron and Steel Institute (at Scunthorpe)—Special Meeting.

## Thursday, October 13

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. J. G. Capewell: "Some Episodes in the Geological History of the Lake District".*

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. J. Monod (Paris): "Specific Factors in the Biosynthesis of Enzymes".*

University of London (at Goldsmiths' College, Lewisham Way, London, S.E.14), at 5 p.m.—Prof. Sir Cyril Burt: "The Delinquent Child". (First of six Lectures on "Psychology and Education". Further Lectures on October 20, 27, November 3, 10 and 17.)*

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. Eric S. Thompson (Carnegie Institution of Washington): "The Rise and Fall of Maya Civilization". (First of three Special University Lectures in Anthropology. Further Lectures on October 14 and 17.)*

University of London (at Queen Elizabeth College, Campden Hill Road, London, W.8), at 5.30 p.m.—Sir Russell Brain: "Dr. Johnson and Science".

College of Preceptors (in association with the School Nature Study Union at 2 Bloomsbury Square, London, W.C.1), at 6 p.m.—Mr. H. R. Syms and Mr. A. Brownlee: "The Keeping of Animals for Observation".

## Friday, October 14

Textile Institute (at 10 Blackfriars Street, Manchester 3)—Mr. J. R. Whinfield: "Textiles and the Inventive Spirit" (Fifth Emsley Lecture).

British Mycological Society (in the Physics Lecture Theatre, Birkbeck College, Malet Street, London, W.C.1), at 11 a.m.—Meeting on "Diseases of Fruit and Hops".

Society of Chemical Industry, Microbiology Group (at th National College of Food Technology, Cranwood Street, Londo E.C.1), at 4 p.m.—Demonstration Meeting—"Some of the Mor Recent Techniques and Apparatus used in Microbiology".

North East Coast Institution of Engineers and Shipbuilder (in the Lecture Theatre of the Literary and Philosophical Society Newcastle-upon-Tyne), at 6.15 p.m.—Commander J. R. H. Bul R.N.: "Impact of the Development of Atomic and Thermonuclea Weapons on the Royal Navy".

## Saturday, October 15

Association of School Natural History Societies (in th Lecture Hall, British Museum (Natural History), Cromwell Road London, S.W.7), at 11 a.m.—Annual Exhibition.*

British Psychological Society (in the Gustave Tuck Theatr University College, Gower Street, London, W.C.1), at 2.30 p.m.—Prof. J. S. Bruner (Harvard University): "Strategies in Thinking".

# APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Senior Lecturer (graduate) in the Department of Mathematic—Registrar, College of Technology and Commerce, The Newarke Leicester (October 12).

Lecturer in Anatomy—The Warden and Secretary, Royal Fre Hospital School of Medicine, 8 Hunter Street, London, W.C.1 (October 14).

Assistant Experimental Officer (with a pass degree or at leas general certificate of education (advanced level) in the Plan Pathology Section—The Secretary, National Vegetable Researc Station, Wellesbourne, Warwick (October 17).

Senior Lecturer (or Lecturer) in Mathematics—The Cler to the Governors, Chelsea Polytechnic, Manresa Road, London S.W.3 (October 19).

Head of the Mechanical Engineering Department; Hea of the Electrical Engineering Department; Head of the Physic Department; Senior Lecturer in Mechanical Engineering; and a Senior Lecturer in Chemistry—The Principal, College of Technology, Belfast, N. Ireland (October 21).

Assistant Biochemist (basic grade) (with a B.Sc. degree wit honours in chemistry or biochemistry, or an equivalent qualification—The Group Secretary, Royal Hospital, Wolverhampton.

Assistant (preferably with some special knowledge of histology in the Department of Physiology—The Secretary, The University, Edinburgh.

Lecturer (with an honours degree in electrical engineering or i physics (and/or a Chartered Electrical Engineer) and with industria experience in electronics or telecommunications) in Electrica Engineering—The Principal, North-West Kent College of Technology, Dartford, Kent

Research Assistant (with a good honours degree in geology, preferably with emphasis on mineralogy, petrology, or structural geology) in the Department of Geology—Prof. J. C. Brindley Department of Geology, University College, Science Buildings, Uppe Merrion Street, Dublin.

Research Entomologist, Senior Scientific Officer or Scientifi Officer grade (with an honours degree in biology and at least tw years postgraduate training or approved experience in scientifi research, with specialization in entomology and preferably wit statistical training or interest in statistics) at the West Africa Institute for Trypanosomiasis Research, for duties primarily in connexion with research upon the behaviour, breeding and longevity of the tsetse fly—Director of Recruitment, Colonial Office, Sanctuar Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/198/04

Scientific Assistant (with a science degree, a good reading knowledge of two European languages (of which one should preferably b other than French or German) and ability to write good English) fo work in scientific information service involving abstracting and indexing—The Director, Commonwealth Bureau of Soil Science, Rothamsted Experimental Station, Harpenden, Herts.

Scientific Officer (with first- or second-class honours degree in biological science, preferably with training or experience in microbiology), to assist in studies on alimentary microflora of farm animals—Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

Scientific Officer (with first- or second-class honours degree in mathematics, physics or electrical engineering or equivalent qualification) for the Air Ministry in London, Maidenhead, Berkshire and Norfolk, for operational research duties, theoretical studies and development work in the field of communications and general electronics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.113/5A.

Scientific Officers (with first- or second-class honours degree in mathematics or physical sciences or equivalent qualification) at the National Physical Laboratory, Teddington, for work in physics (including radiology), mathematics and electric computers (Ref. A.338/5A), and metallurgical chemistry (Ref. F.449/5A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No.

Senior Entomologist at the Glasshouse Crops Research Institute—The Secretary, Glasshouse Crops Research Institute, Rustington, Littlehampton, Sussex.

Senior Experimental Officer (with G.C.E., advanced level in science subjects, or equivalent qualifications) to take charge of the Technical Records Section at Dounreay Works, Caithness—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, Lancashire, quoting 1113.

The SCORAH OXY-COAL GA BLOW PIPE

specially for workin BOROSILICATE GLASSES (Pyrex, Phoenix, Hysil, etc.

● Five jets an central pilot light - flame size selecte INSTANTANEOUSLY

● Rotating turre head for easy jet selection.

● Auxillary suppl of oxy coal mixture fo hand torch.

*Minimum oxygen consumption*
*Maximum economy*

A modern oxy-coal gas blow-pipe of sturdy construction evolved throug years of practical experience in glass manipulation. A nearly silent flam from pin point to one capable of working 100 mm. tubing at a flick of th turret. To the inexperienced it gives confidence, to the experience it is an assurance of efficiency and successfully completed work. A uniqu instrument for the research laboratory or workshop. Send for Leafle BP/N2.

*Obtainable only from*

Price **£19.10.0**

# THE PURPOSE OF UNIVERSITY EDUCATION

ALTHOUGH the importance of general education, and particularly of securing more breadth in raining the scientist, or indeed any type of specialist, was emphasized at least as much at the Conference of Rectors and Vice-Chancellors of European Universities last July in Cambridge as at the subsequent meeting of the British Association at Bristol, there seems to have been little progress in suggesting means of securing it. The Cambridge Conference, indeed, noted a progressive deterioration of the balance which should exist in the universities between specialization and general culture, and a report presented to the Conference urged a stand against the current inflation of the curriculum. There was, however, little support for a preliminary year of compulsory studies of general cultural subjects, or for any system which obliged arts students to study a scientific subject and science students an arts subject for much of their university career.

At this Conference the means generally favoured were optional courses in subjects of general cultural interest, which could be taken without a subsequent examination, or a general course designed more specifically to prepare the student for his specialized courses. It was also recognized that it is desirable to deepen the student's understanding of his own special subject in the context of a wider background. This method appeared to be regarded as the most promising means of restoring the traditional balance between specialization and general culture; but the discussions seemed to lack either real unity or the note of urgency which Dr. J. Bronowski contrived to bring into his address at Bristol and Dr. Eric James into his lecture to the Science Masters' Association on "Science and Citizenship".

Perhaps more notable was the absence of any suggestion that the proper place in which breadth and general education should be acquired is in the schools. This might have been even more regrettable but for the appearance in the following month of the report of the sub-committee appointed two years ago by the Committee of Vice-Chancellors and Principals to consider and make recommendations in regard to university entrance requirements in Britain. It is clear from this report that, except for recommending that only two subjects should be required at the Advanced level of the General Certificate of Education instead of three, there is little unanimity on matters of importance to sixth-form school and first-year university teaching. Agreement on this point was indeed reached at the outset of the six meetings of the sub-committee concerned; and while the sub-committee agrees that it may be desirable to continue to require three passes at the Advanced level on the science side, the report gives little indication of the reasons for a recommendation which admittedly makes real education very difficult or even impossible for the science student. The report is, on the contrary, mainly concerned with the reasons for the divergence of views, which have produced two minority reports.

One side maintains essentially that the present requirement of prescribed subjects should be maintained, and that unless this is done the curriculum at many schools will be narrowed to subjects which are clearly utilitarian and directly vocational. It is argued that it is unrealistic to say that the schools should take full responsibility for the general education of their pupils. On the other side, it is contended that, on the contrary, no number of passes at the Ordinary level ensures the standard of general education that university teachers desire their students to possess and that, while universities and schools have a common interest in promoting a broad and liberal education side by side with appropriate specialized studies, the responsibility for general education must be taken by the schools alone.

The poor reception of this report may well be due in part to the lack of urgency and realism which seems to have characterized its proceedings. If its members had been really convinced of the importance of general education, either for the specialist or the ordinary citizen, it is difficult to believe that such relatively small points could have kept the two sides apart. There is lacking, for example, the conviction which marked the addresses of Mr. J. F. Wolfenden and of Dr. Bronowski at Bristol, or the contributions of Sir Philip Morris, Prof. N. F. Mott, Prof. F. A. Vick and Dr. A. W. Barton to the joint discussion between Sections A and L on the training of physicists (see *Nature*, October 7, p. 678). The means will be discovered when it is believed that the end really matters; and if the universities are really interested in discovering the state of the general education of their students at the time of admission, they will not be prevented from ascertaining that state even if it is necessary to devise an entirely fresh means of doing so. Mr. T. W. Holland, headmaster of Reigate Grammar School, has suggested the institution of a general paper which would ensure that the student had read widely and to some purpose, that he had gone deeply into the history and geography of another country and that he was not "scientifically illiterate".

It is clear from the report that some members at least of the sub-committee lean towards such an idea, and the discussion at Bristol on the training of physicists indicated a far greater disposition to re-examine the underlying issues, both by schools and by universities, than is apparent from the sub-committee's report. Sir Philip Morris, for example, opening the discussion, took for granted much that Mr. Wolfenden had emphasized as to the necessity of a fully educated man possessing both the deep insight into human nature that is most conveniently and comprehensively acquired from the written and printed record, and the first-hand personal experience of human actions to be gained from deep and practical immersion in human affairs, personal, social and political. He agreed, too, as to the importance of the non-scientist having some understanding of the scientist's outlook on the physical universe; indeed, as

Mr. Wolfenden had put it, in our present civilization the view that more is required than just the human without the scientific, or just the scientific without the human, was not seriously challenged in the discussion that followed.

Sir Philip Morris posed some searching questions: Should science be taught in the secondary school as separate subjects? Do scientists value the acquisition by the general citizen of an understanding of the scientific outlook sufficiently to support the diversion of effort to that end from the acquisition of new knowledge? Is the structure of postgraduate education adequate or does it, too, require re-examination? Are we relying too much on research as a means of postgraduate training and education?

A noteworthy feature of the discussion at Bristol was the evidence it provided of a readiness to re-examine first principles, to experiment with new methods and to make drastic changes if required. Prof. Mott and Prof. Vick were as ready as Sir Philip Morris not merely to ask searching and leading questions, but also to seize opportunities of experimenting with new ways. They recognize the importance of close and new ways of co-operation between school and university and realize that suggestions thrown out must be put to the test—for example, that of Prof. Mott for allowing a general paper to play a major part in determining the award of scholarships. While Prof. Mott was emphatic that general education is the responsibility of the school, and in particular that it is essential for the sixth-form scientist, there appeared to be little difference between his point of view and that of Dr. A. W. Barton, who described some of his attempts at the City of London School to assist boys to make a wise choice of their sixth-form courses. Prof. Mott believes that it is desirable that the decision to read science should be made as late as possible in a boy's time at school; and this is quite consistent with Dr. Barton's claim that the sixth-former intending to read science should be allowed to spend a major part of his time on science, for Dr. Barton's plea was based on the assumption that adequate time had previously been given to general education. Furthermore, Dr. Barton argued that the school's function is to stimulate curiosity, to develop the critical faculty and impart some understanding of the scientific attitude and method.

If this is achieved, the ordinary sixth-former should acquire exactly the basis for his general education that he needs as a citizen of this modern world, whether he follows a scientific career or not. Moreover, he will also acquire very largely the broad and general education that Prof. Mott requires as a basis for a university course. Dr. Barton's ideas, moreover, lend some support to the view argued most eloquently by Prof. Vick that it is possible to build around physics as a major component an education for future Civil servants, politicians and industrialists as deeply and widely stimulating as that provided by the 'Greats' or 'Modern Greats' of Oxford. Prof. Vick maintained that in this way we could develop, for example, intellectual courage and honesty, the ability to assess a situation, to think logically and quantitatively, and to handle abstract ideas as well as impart some understanding of the meaning of scientific proof and recognition of the limitations of science. He was as confident of the practicability of working out such courses as Prof. Mott was that the general education for the sixth-form scientist is a matter of fitting the wider studies into the curriculum and making the reward for working at them sufficiently attractive.

There is thus much more reason than the report on University Entrance Requirements itself implies for believing that the schools and the universities of Britain are ready to come together in this matter, and to contemplate even drastic changes if necessary. The addresses and discussions at Bristol have made clear to a wider audience that the educated man to-day—and even more in the next two or three decades—must have a clear understanding of the outlook and method of science. The non-scientist must possess a framework into which to fit new knowledge, a vocabulary with which to handle it, standards by which to test and to tell genuine knowledge from nonsense, just as the scientist must possess an understanding of human issues and human experience. To insist that science must become part of our culture is not indeed to argue that the scientist should have the deciding voice in local, national or international affairs: it is simply to maintain that his training must qualify him to make perfectly clear to his fellow-citizens, at all stages and at all relevant points, what will be the consequences, in scientific terms, of any decisions which are contemplated, and equally that those fellow-citizens receive an education which enables them to understand what the scientist is saying.

The educated man must thus, as Mr. Wolfenden contended, be able to move with some facility in at least two spheres. He must be able to appreciate in something like perspective the achievements of the human race, in government, literature, art and social living, and, secondly, he must be able to move with some facility in the realm of abstract ideas. It does not matter which field he finds most congenial; but Mr. Wolfenden is clearly right in holding that we should seek not to give the same kind of education to all but, recognizing the differences between people, to educate them rather according to their ability, age and aptitude.

To do this might go far to assist in the adjustments that will be called for if we are to provide, not merely the educated men and women that will be required in industry and in the government service and for the continuous acquisition and application of new knowledge, but also the ordinary citizens who are capable of taking intelligent decisions in the many affairs of local or national politics in which scientific and technical issues are involved. Those adjustments, moreover, are unlikely to be made unless the objective is recognized as fully worth while, and education is seen as an inter-related whole. Qualitatively as well as quantitatively, the provision to be made for the education of the scholar and the scientist must be considered in relation to that made for the training of the administrator and man of affairs, the technologist, the technician and the ordinary citizen whose formal education terminates at secondary school level.

What does seem to be emerging from current discussions is the recognition of the possibility that available resources may be utilized to the best advantage if there is a more general disposition to consider the wider perspective and less tendency to push sectional claims to extremes. Those who insist most strongly on the importance of a general education for the scientific specialist, or of some understanding of the outlook and achievements of science on the part of those not entering on a scientific career, are not advocating any relaxation of university standards. They are, on the contrary, suggesting that university practice and standards should be adjusted to take closer account of the advances in human thought and experience which science has made possible. It is not enough for the teaching of specific disciplines like physics and chemistry to take account of the immense advances in their own fields. The technique of teaching itself requires adjustment, and the scope of university work must have regard both to the changes in the schools and in the level of education of the adult population. Extra-mural activities like adult education need reviewing in relation to the purpose and the resources of the universities, and in relation to the impact on adult education of such new media for the communication of ideas as broadcasting and television.

This is not to suggest that the universities bear the sole or even the primary responsibility for adult education, for example. Their responsibilities in that field can be neither defined nor discharged without the co-operation and support of other bodies, or without regard to what, for example, professional institutions and local authorities are doing, any more than they can fulfil their functions in regard to the general education of their students without regard to what the schools are doing or without close co-operation with the schools. Such co-operation will become the easier and closer when we have clear ideas both of the functions which the different institutions can best fulfil and their relation to the whole task of producing an educated community. The university must indeed always bear a major responsibility in that task; but its part may be more easily seen and the more effectively played if there is kept in mind the whole ideal of the university as a community of masters and scholars in pursuit of knowledge and learning, who also form a community of men and women living together and seeking the truth, and that not in their own narrow subject alone. When we regard the university, on the contrary, as merely a scholar's workshop and laboratory, a place for students to study, teachers to teach, and the investigator to carry out research, it fails to bring to its members or to the whole community the full service and inspiration that lie within its power. The nature of the university's contribution to the training of men and women to serve the community, to the equipment of the adult citizen to meet the needs of the modern world, may well need re-examination, and also the methods used to make that contribution; but it is above all essential that we should keep in mind that supreme function of the university as a community dedicated to the search for truth and the fearless communication of ideas.

In this sense the universities can never abdicate their responsibilities for leadership in the community without endangering their own existence. It is not simply that the community looks to them to give some broad indication of the implications for human thought and living of advances in knowledge and changing technologies—of the consequences, for example, of nuclear weapons or of the development of nuclear power and the spread of television. The community needs centres of independent thought and criticism, in which the value of international interchange of thought is clearly demonstrated, just as much as it needs institutions to provide it with the fully trained and really educated men and women capable of handling alike the scientific and technical problems of government and industry and the human and social issues that are also involved, and to provide the new knowledge upon which the advance of science and technology depends. It needs chiefly, however, men and women who are both able to draw imaginatively on past human experience, and are no less competent to face the future with vision, with understanding and courage, and to fashion and create the new institutions and new loyalties that changing needs demand. If that is to be done, the creative thinking and experiment must begin within the university itself. Testing and re-shaping where necessary its own methods and institutions—but safeguarding and upholding the highest standards and traditions of university life and work—the university must seek to further the mutual understanding with the society outside its walls which is essential both to the health and sanity of society and to the continuance of the external support upon which the university itself depends.

# PLANT ANATOMY RESEARCHES OF I. W. BAILEY

**Contributions to Plant Anatomy.**

By Prof. Irving W. Bailey. Pp. xxvi + 262 + 23 plates. (Waltham, Mass.: Chronica Botanica Company, 1954.) 7.50 dollars.

THIS volume includes reprints of a few of Prof. I. W. Bailey's papers, selected mainly to illustrate how techniques from other sciences have been adapted to botanical problems and to direct attention to the value of collaboration between the sciences. After a childhood in Peru, Bailey entered Harvard, where he became instructor in forestry in 1909 and professor of anatomy in 1927. In later years his width of experience made him an invaluable adviser in forestry research and an ideal director of the reorganization of Harvard's botanical resources.

Throughout Bailey's work the problem of the origin and evolution of the Angiosperms was much in his mind and provides the link between such diverse aspects of his work as wood anatomy, floral morphology and palæobotany. To my mind his most important researches were those on the cambium, and it is striking how many of the basic facts in botanical teaching owe their confirmation to his work. The cambium is a difficult tissue to handle, and the success of Bailey and his collaborators in solving outstanding problems is largely due to excellence of technique; it is one point to regret that he has never, to my knowledge, found it possible to give a full and precise account of his cambial techniques. The soundness of his work on the cambium is convincing, and his conclusions have stood the test of time. He was the first to establish the uninucleate condition of the long fusiform initials of the cambium in *Pinus* and to show that the same nuclear volume controls the cytoplasm of ray and fusiform initials, although the volume of the latter may be 500–1,000 times greater. The description of mitosis in pine fusiform initials is one of the most spectacular in botany, while the application of a modified vacuome technique enabled Bailey and Zirkle to demonstrate the highly vacuolated condition of these remarkable meristem cells.

A problem of tree growth which had long exercised the minds of botanists was the method of increase in number of fusiform initials in the widening cambial periphery; the precision of Bailey's technique and a comparison of a wide range of types enabled him to state that in Gymnosperms and many of the less-specialized Dicotyledons the increase is brought about by occasional, relatively transverse divisions and the elongation past one another of the products, while in the most specialized types radial longitudinal divisions occur. These studies occupied the period 1919–30; but some of Bailey's later papers on wood show his phylogenetic interests, as, for example, the consideration of the ways in which vessels have originated in Tracheophyta, with the conclusion that they have arisen independently five times, including different origins in Dicotyledons and Monocotyledons. Close study of wood anatomy in some living Gymnosperms directed attention to the importance of precise information on variability for comparison with fossil types.

Between 1934 and 1939 Bailey turned his attention to chemical and physical methods for the investigation of cell walls, collaborating with Kerr, Vestal and Berkley in different aspects of the work. Again, some of the results have become basic in teaching, such as the properties and non-cellulosic nature of the middle lamella and the distribution of lignin in the secondary wall in the interstices of the cellulosic matrix. In X-ray studies he was one of the first to elucidate some of the aspects of the structure of cellulose walls.

In floral morphology the development of clearing techniques facilitated study, and the extremely interesting type of stamen and carpel in the previously undescribed *Degeneria*, along with studies of the carpels of Winteraceae and related types, will attract carpel morphologists. On a different line, the study of myrmecophytic species of *Cecropia* provided interesting facts about feeding habits of Attine ants and led to an assessment of Schimper's teleologically based theory of myrmecophily.

A review of this book cannot omit reference to the most attractive sectional title pages, head pieces and vignettes. Inspired by Bailey's papers, Prof. B. G. L. Swamy has illustrated in this form some of the main evolutionary trends and topics discussed. Special reference must be made to the last vignette, which illustrates the evolution of tracheal elements in the form of a 'herb' diagram derived from a motif common in paintings of the Mogul School. The use of the pattern of the cross-section of the wood of a coniferous root for the cover lining is most appropriate.

This is an unusual book which should certainly find a place on botanical shelves as a guide to the work and scientific approach of one of America's greatest botanists. The volume contains a full list of Bailey's publications, and the frontispiece shows a characteristic photograph of the author.

# X-RAY DIFFRACTION IN PHYSICAL AND CHEMICAL LABORATORIES

## X-ray Diffraction by Polycrystalline Materials

Edited by H. S. Peiser, H. P. Rooksby and Dr. A. J. C. Wilson. (Physics in Industry.) Pp. 725. (London: Institute of Physics, 1955.) 63*s*.

THIS work recently published by the Institute of Physics will certainly come to be one of the most-used volumes in X-ray laboratories. It is written for 'diffractionists'—that is, those who work with X-rays as a tool for studying the physics and chemistry of solids but not for determining structures.

It is not at all a text-book, but one for workers in the laboratory. It can only be appreciated and properly used by a man of science having already a good grounding in crystallography and in the theory of X-ray diffraction. The arguments recapitulated in the first chapter will clarify the uncertainties of a beginner but do not pretend to introduce him to the subject of crystallography.

The aim of the authors has been to outline the methods actually in use in the study of crystalline powders. First place is given to descriptions of apparatus and techniques—above all, the most recent ones. Those who may be unhappy about their own collection of literature references need no longer worry: the authors have given them all the references that may be missing and, what is best of all, a summary, both brief and clear, of all the important works which have appeared during the past twenty years. It is a remarkable feat to have presented this considerable documentation in such an attractive manner and so well laid out. For example, if a scientist has to make a study of structures at high temperatures, he can find the method that is best suited to his needs and the original references which will give him the details for the construction of apparatus.

Certain chapters are original monographs—for example, those on counters, microbeams, diagrams of organic fibres, etc. The chapters of the last part of the book, on some applications, are particularly welcome: they appear to contain the essence of many investigations. Against this must be set the fact that certain points remain but slightly developed, despite the interest they have for those concerned with the physics of the solid state: such topics are the analysis of the shape of the lines from distorted crystals, and the determination of the parameters of order in solid solutions. It must be admitted, however, that mention is made of the study of the single crystals, and it is difficult to reproach as being incomplete a book which already runs to more than seven hundred pages.

The book is the collective work of some thirty authors. Thus each topic is dealt with by a specialist, and each author's personal experience of his subject explains the lively approach of the work. All annoying heterogeneity has been completely smoothed out by the three editors: Dr. H. Rooksby, on techniques; Dr. A. J. C. Wilson, on methods of interpretation; and Dr. H. S. Peiser, on applications. All the authors are British, and to me as a Frenchman this shows how numerous in Britain is the school of X-ray crystallographers continuing brilliantly the work of their teachers who founded this science.

A. Guinier

## ERASMUS DARWIN

The Temple of Nature; or, the Origin of Society
A Poem, with Philosophical Notes. By Erasmus Darwin. (In Russian.) Pp. 239 + 6 plates. (Moskva: Izdatelstvo Akademii Nauk SSSR., 1954.) 12 roubles, 80 kopecks.

It may be that the great admiration felt for Charles Darwin in the U.S.S.R. induced the Academy of Sciences to re-publish the Russian translation of this poem of his grandfather. "The Temple of Nature", by Erasmus Darwin, was originally published in 1803, a year after his death. The original Russian translation of this poem was published in 1911 in the *Journal* of the Ministry of Education in St. Petersburg. The translator, N. A. Kholodkovsky (1858–1921), was rather a remarkable man—a professor of zoology, a poet and a gifted translator of Milton, Shakespeare, Byron and Goethe.

"The Temple of Nature" is probably less known than "The Botanic Garden" by the same author. It is a didactic-scientific poem written in pseudo-classical style in heroic couplets. It is not a major poetic work, but it is not without certain charm and is full of humour, much of it clearly unconscious. Here is a fragment of it, chosen at random:

> "In earth, sea, air, around, below, above,
> Life's subtle woof in Nature's loom is wove;
> Points glued to points a living line extends,
> Touch'd by some goad approach the bending ends;
> Rings join to rings, and irritated tubes
> Clasp with young lips the nutrient globes or cubes;
> And urged by appetencies new select,
> Imbibe, retain, digest, secrete, eject."

The translator really did a wonderful job not only in bringing out the full meaning of the poem but also in preserving the style, rhyming sequence and metre of the original. To do this he had to expand the original 1,928 lines into 2,247 lines.

In addition to the full text of the poem, the volume contains Charles Darwin's life of his grandfather in translation, two sets of notes by Erasmus Darwin, also in translation, one set by the translator and one set by the editor, who also provides a biographical sketch of the translator. There are two portraits of Erasmus Darwin, one of the translator and other illustrations.

The book is carefully edited by E. N. Pavlovsky, director of the Zoological Institute of the Academy of Sciences in Leningrad, a significant fact especially when it is realized that the translator, N. A. Kholodkovsky, was also a prominent zoologist.

The poem is an expression of Darwin's scientific views on the origin and development of life, the evolution of the mind and the growth of society. Like his "Botanic Garden", this poem is an invaluable record of scientific thought at the end of the eighteenth century. The publication of the Russian translation of this is not intended as a homage to a minor English poet, but as an important contribution to the ever-growing Russian literature relating to the history of science.

S. I. Tomkeieff

## SYSTEMATIC ZOOLOGY

Methods and Principles of Systematic Zoology
By Ernst Mayr, Prof. E. Gorton Linsley, and Prof. Robert L. Usinger. (McGraw-Hill Publications in the Zoological Sciences.) Pp. ix + 328. (London: McGraw-Hill Publishing Co., Ltd., 1953.) 51s.

Novelty usually brings rapid developments in a science followed by a spate, sometimes superabundant, of text-books and treatises. The novelty of the new systematics is, however, unspectacular either in methods or results, and development in taxonomy has been correspondingly slow, with the need for a comprehensive treatise growing equally slowly. The need has, however, been very acute for many years, and zoologists can count themselves fortunate that it has now been satisfied in proportion to its intensity. The three authors have brought to the task not merely the essential knowledge but also breadth of understanding and an ability for lucid and logical exposition.

The book, "a concise presentation of the methods and principles of zoological classification", is subdivided into three parts, of which the first, and shortest, deals with the history of taxonomy and proceeds logically to consider changed concepts and the status of the hierarchical categories. Part 2, taxonomic procedure, is a step-by-step guide from advice on the selection of the problem and assembling the pertinent material and information, to the preparation of the paper describing the results, selecting its title and seeing it through the press. Much of this part is, of course, elementary; but much that is complex is made to seem elementary, not by over-simplification but by clear thinking and presentation. The phenomena the taxonomist will, or may, encounter and the methods he will, or ought to, use for dealing with them are themselves treated in taxonomic fashion and grouped in logical categories. It is a sorry comment on human frailty that nomenclature, which should be merely the handmaiden of zoologists, has so beguiled some and bedevilled others that the section dealing with it needs the equivalent of a quarter of the whole book. But that is not the fault of the book, nor of its authors, and students will find the section very useful even though the important Copenhagen Decisions (1953) were not available in time for inclusion.

"Methods and Principles" is an essential text-book for all students of evolution and taxonomy and a valuable reference book for practising systematists however experienced they may be. Much of it should be read by any zoologist who would claim to have a broad and liberal understanding of his subject. There are, naturally, some expressions of opinion that are controversial, but errors are notably few and generally insignificant. The authors will therefore find it especially galling that the statistical section, which the non-mathematically minded may follow blindly, contains a slip; the numerical value of the standard error of the difference between means (p. 142) is not an index of significance.

H. W. Parker

# THE INTERNATIONAL WOOL TEXTILE RESEARCH CONFERENCE, AUSTRALIA, 1955

WOOL is a most versatile fibre, and many facets of interest to scientists and those concerned with its growth and processing were examined at the Wool Textile Research Conference, held successively at Sydney, Geelong and Melbourne, under the chairmanship of Dr. F. W. G. White, during August 22–September 9. The Conference was promoted, with much foresight and imagination, by the Commonwealth Scientific and Industrial Research Organization (C.S.I.R.O.) to mark the expansion of research into the wool textile field in Australia. Never before had so many wool scientists and technologists assembled together from many countries of the world. The excellent planning and organization of the many sessions held for the presentation and discussion of papers (some 140 or so in number) ensured the success of the Conference, despite the wide range of scientific investigations that the Conference encompassed.

Many of the fifty-three overseas delegates, from Great Britain, the United States, France, Sweden, Germany, Japan, India, South Africa, Canada and New Zealand, attended by invitation of the Australian Government, and all would wish to express their appreciation of the hospitality received from both organizations and private individuals during this memorable occasion.

In addition to the scientific sessions, tours of the Sydney–Geelong region were organized so that delegates could learn at first hand of wool-growing, pastoral improvement, and irrigation in Australia.

Wool research under the Commonwealth Scientific and Industrial Research Organization has rapidly expanded in recent years, chemistry and biochemistry being directed by Dr. F. G. Lennox at Melbourne, physics and engineering by Dr. Burgmann at Sydney and technical development by Dr. M. Lipson at Geelong; reference should also be made to the McMaster Animal Health Laboratory at Glebe, Sydney, the Sheep Biology Laboratory at Prospect, the Animal Health Research Laboratory at Parkville, and other stations of the Organization and university departments. Some hundred delegates attended from these institutes. The overseas visitors were able to see the work in progress, which included amino-acid and peptide analysis, the study of crimp and other physical properties of fibres, and a new approach to solvent-scouring of wool. Australian workers contributed more than fifty papers, while those from abroad included twenty from the Wool Industries Research Association of Torridon, Leeds, eighteen from the University of Leeds, nine from other delegates from Britain, thirteen from the United States, and twenty-three from other countries.

Several lectures, some to the delegates and scientific observers from universities and research centres and others open to the general public, were given during the Conference period. The public lectures each attracted an audience of five to six hundred, and this, together with other evidence, clearly indicated the public recognition of the contribution of the Commonwealth Scientific and Industrial Research Organization to the service of the community. The inaugural lecture at the Conference was given by Prof. W. T. Astbury, of the University of Leeds, who, in his own inimitable style, showed how early work on the structure of keratin fibres and materials had stimulated much of present-day thought and research on proteins. Dr. E. G. Carter, of the International Wool Secretariat, gave an excellent account of the part played by science in the study and use of wool to a large public audience at the University of Melbourne. Perhaps the most stimulating lectures, however, were those given by Prof. Robert B. Corey, Dr. F. Sanger and Prof. Emil L. Smith. Many of the overseas delegates had previously heard lectures from these investigators, but it is certain that even these delegates were again thrilled to hear a first-hand account of the masterly researches of Corey and Pauling on the configuration of the proteins, of Sanger on the structure of insulin, and of Smith on structure determinations of papain. Everyone present appreciated the significance of Sanger's statement that the molecular weight of insulin is 5733.

In addition to these Conference lectures, many delegates addressed local societies and other groups interested in scientific and technical advances in the use of wool. There was, in fact, a wide exchange of opinions and information and there is little doubt that many opportunities were taken to co-ordinate research between different countries.

It is impossible within reasonable space to give a detailed account of all the papers presented at the Conference; but a useful purpose will be served by giving, for each of the main sciences, the outstanding features, with special reference to new work, that were made available either by a single paper or by a group of contributions. Some idea of the amount of material made available to the Conference will be gained by the anticipated size of the Conference Proceedings, to be published in the near future, namely, more than 2,000 pages that will occupy five or six volumes.

## Chemistry

In the chemical studies, the emphasis was understandably on proteins. Dr. F. Sanger (University of Cambridge), in addition to describing the investigations carried out by his team of research workers on the distribution of the cystine residues in insulin, with special reference to the cyclic structure formed by intramolecular dithio linking, discussed cysteic acid peptides formed by oxidation and subsequent partial hydrolysis of wool; paper ionophoresis under high voltage indicates a very complex mixture in which serine– and glutamic acid–cysteic acid peptides predominate. Researches on the enzyme papain, parallel in many ways with those of Sanger and co-workers on insulin, were reported by Prof. Emil Smith. The crystalline protein and also its mercuric derivative have been studied and much of the amino-acid sequence has been elucidated. One interesting feature of this work is that, of the eight sulphur atoms present in the molecule, only six can be accounted for as cystine or cysteine and, in this connexion, it should be noted that in wool only 85–86 per cent of the total sulphur appears to be present as cystine–sulphur, due, according to Dr.

D. H. Simmonds (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne), to the presence of 14–15 per cent of elementary sulphur. This latter finding was reported in a paper by Simmonds in which were given complete amino-acid analyses for four samples of wool fibre.

The availability of a complete amino-acid analysis for wool would mark the end of the first stage in the study of the keratin molecule. Unfortunately, there are several problems to be resolved with regard to the data available. Simmonds's data agree reasonably well with those of Dr. A. Robson and M. C. Corfield (Wool Industries Research Association, Leeds), which were also reported to the Conference; but there are differences in the values for certain of the amino-acids that appear to be outside the tolerance of accuracy of the analytical methods used. In addition, the content of some amino-acids clearly differs with different wools; this is undoubtedly true of cystine and tyrosine, and possibly occurs with phenylalanine, glycine, aspartic acid and threonine. The data available account for 96 per cent (Simmonds) to 99 per cent (Robson and Corfield) of the total nitrogen, and hence the unknown sulphur fraction must exist as elementary sulphur—a theory not readily acceptable to most protein chemists—or to the presence of a polysulphide group in place of the cystine–dithio linkage.

Many papers were concerned with the constitution of the keratin molecule. Dr. S. Blackburn and G. R. Lee (Wool Industries Research Association, Leeds) reported that the method of hydrazinolysis of Akabori *et al.* shows glycine, alanine, serine and threonine to be carboxyl terminal groups in intact wool. Most workers in this field, however, are concerned with the obvious heterogeneity of the wool fibre and have attempted to separate, either from the whole fibre or some histological fraction, for example, cortical cells, a soluble protein or protein degradation product. Experiments in this direction, carried out by means of thioglycollic acid, were described by Dr. F. G. Lennox and by J. M. Gillespie (both of the C.S.I.R.O. Wool Textile Research Laboratory, Melbourne), while Dr. P. Alexander and Dr. L. F. Smith (Chester Beatty Research Institute, London) claimed that oxidative fission, achieved by peracetic acid followed by extraction with aqueous ammonia, affords products of a lower degree of peptide-chain degradation. I. J. O'Donnell and E. F. Woods (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne) reported a comparison between the reductive and oxidative methods, and Dr. B. S. Harrap (of the same Laboratory) examined some of these preparations for molecular weight by the spreading monolayer technique; for α-keratose he obtains values ranging from 7,500 to 70,000 depending on the *p*H and ionic strength of the solvent. Prof. H. Zahn and J. Meienhofer (University of Heidelberg) obtained products, which they call wool gelatin, by extraction of wool with cold water; but there is some doubt as to the wool keratin being the direct source of their material. The bearing of the nature of soluble protein material from wool on the regeneration of wool fibres was discussed by Dr. F. Happey (Bradford Technical College).

Much attention was given to the reactivity of the disulphide bonds in proteins and peptides. Alkaline treatment of wool results in formation of lanthionine, and this reaction was discussed by Prof. A. Schöberl and Annemarie Wagner (Veterinary School, Hamburg), by Prof. H. Zahn, and by Dr. S. Blackburn and G. R. Lee (Wool Industries Research Association, Leeds); these workers described a method for the determination of lanthionine based on the spectral absorption of the ninhydrin colour, whereas Dr. E. O. P. Thompson (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne) resorted to bromine oxidation. The separation of the diastereoisomerides of lanthionine was described by Schöberl and Wagner and by Blackburn and Lee. The mechanism of the formation of lanthionine and the preparation and properties of derivatives of lanthionine were given in papers by Zahn and by Dr. J. M. Swan and co-workers (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne).

The attention that has been given to the extraction products of high molecular weight and to the products of partial hydrolysis was reflected in the papers devoted to their separation. Thus Dr. R. L. M. Synge (Rowett Research Institute, Aberdeen) discussed the separation of larger peptides and advanced considerations that merit serious study, while the paper by Dr. A. J. P. Martin (National Institute for Medical Research, London) on the partition chromatography of proteins was a valuable contribution to this subject; in this connexion, Dr. Sanger recommended the use of paper ionophoresis at high voltages for use with peptides.

A fuller utilization of wool has been developed by chemical treatment of the fibre; this was shown by papers on this subject, especially those by Prof. J. B. Speakman and his co-workers of the University of Leeds, who gave a series of papers describing investigations on the chemical mechanism of permanent set, on cross-linking by the use of formaldehyde and of ninhydrin, and on the setting of stained fibres at low temperatures. Prof. Zahn, in a lecture to the Conference, described the use of mono- and bi-functional cross-linking agents and their effect on the resistance of the fibre to degradative processes, and a paper by J. E. Moore and Dr. H. P. Lundgren (U.S. Department of Agriculture) referred to dimaleimides as cross-linking agents. Prof. M. Oku and I. Shimizu (Kobe University, Japan) claimed that the stability and mechanical properties of wool are improved by formaldehyde cross-linking, achieved by treatment with hexamethylenetetramine.

A new approach to the chemical modification of the wool fibre was shown by Wikstrom and co-workers (Swedish Textile Research Institute, Gothenburg), who found that the surface reactivity of the fibre could be increased by treatment with chemical reagents, especially hydroxyl ions and organic solvents; it is of interest to note that W. G. Crewther (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne) noted in his paper that hydroxyl ions increase the susceptibility of wool fibres to proteolytic attack. A paper of practical importance in the shrink-proofing of wool, given by R. Bentham, C. B. Stevens and Prof. C. S. Whewell (University of Leeds), dealt with the action of hypochlorites on wool that had been modified by treatment with alkalis, acids, deaminating agents and dyes. All these contributions place emphasis on the part played by the cuticular layers of the wool fibre in chemical processes.

The general trend of work on the chemical modification was well exemplified in a lecture by Dr. H. P. Lundgren, who discussed the stability of the hydrogen-bonded wool structure, as shown by the reaction with β-propiolactone, the stability of the disulphide bonds, the behaviour of wool on heating or exposing to ultra-violet light and the protection of wool against such agents by the use of, for example, titanium alkoxides; one interesting observation in this lecture was that the yellowing of wool is promoted by suint, one active principle of which is urocanic acid (a glyoxalylacrylic acid).

## Physics

The application of reaction-rate theory of visco-plasticity to wool was the subject of a lecture by Prof. H. Eyring (University of Utah) and of one of the physics sessions. This theory often merely expresses the usual experimental results in an alternative form, but a stimulating paper by Dr. L. Peters (University of Leeds) attempted to relate the statistical parameters to a molecular model of the fibre. The interaction of wool and water again brought reaction-rates to the fore, and some beautiful experimental work from the C.S.I.R.O. Wool Textile Research Laboratory at Sydney provided data for the very rapid diffusion of water into single fibres. A paper by F. L. Warburton (Wool Industries Research Association, Leeds) showed how useful the wet-bulb theory could be for calculations of drying and conditioning on an industrial scale.

A review of the present position of research on worsted spinning was contributed by J. Ingham (Wool Industries Research Association, Leeds), and Dr. Margaret Hannah (University of Leeds) discussed problems of high-draft spinning. This session also considered woollen carding and spinning and the design of experiments when industrial plant has to be used. Fibre arrangement and the behaviour of fibres during mechanical processing were surveyed in a series of papers presented by British and Australian delegates. Wet processes, together with dyeing and finishing, were discussed in three sessions, the most interesting development being the solvent scouring system used at Geelong. Much information was also made available on the degradation of wool during wet processing, and the full report of the Conference should provide manufacturers with an excellent guide to precautions that are necessary when subjecting wool to acid or alkaline conditions. The sessions on manufacturing processes were concluded by a symposium at Geelong with some four hundred members of the local textile industry, where a lively discussion followed short addresses by Dr. A. B. D. Cassie, Dr. J. G. Martindale and Prof. C. S. Whewell.

## Histology

The fine histology of wool and the recent discovery of its bilateral structure provided much material for exchange of experience and opinion. There seems little doubt that the bilateral structure contributes largely to the crimp of wool, and because of the different reactions of the two structures to swelling, it may well be a principal factor in maintaining the bulkiness, and therefore the warmth, of wool fabrics. Although much was discussed about the wool follicle and its blood supply, no suggestion was made as to how this difference in keratinization, apart from references to Auber's work on detailed segmental keratinization, or possibly even in chemical composition, might arise. The histology of the wool fibre and that of its follicle are subjects that require much more research, possibly with entirely new approaches. The fine structure of wool is slowly being revealed by the electron microscope, and infra-red absorption spectra coupled with deuteration of the protein chains not locked in crystallites offer opportunities for considerable advance in our knowledge of wool structure. It must be remembered, however, that although the crystallographers may solve the problem of the crystal structure of keratin, they will have thrown only a little light on how wool works. The contributions by Dr. R. D. B. Fraser (C.S.I.R.O. Wool Textile Research Laboratory, Melbourne) and by G. King (Wool Industries Research Association, Leeds) on the infra-red spectra of swollen fibres were, therefore, most welcome.

There were also sessions on wool as a textile fibre, where students of genetics and nutrition sought guidance from the physicists and chemists on the fibre characteristics desired by the wool manufacturer. These discussions revealed again the uncertainty that exists concerning the uniformity of the physical and chemical properties of wool; and until greater accuracy is attained in such measurements, the biologist can only seek greater regularity of length, diameter and crimp. Many of the difficulties facing the physicist and chemist in finding variations in the properties of wool are probably due to the heterogeneous samples that normally come their way, and one outcome of the Conference has been the establishment of contacts that will provide wool samples from flocks of a definite type of sheep, or even from different parts of one or more fleeces: in this connexion, a scheme has been proposed for the preparation of, for example, large samples of finely cut, clean wools so that workers all over the world may have a common source of material for amino-acid analysis, etc.

As a final note, it is appropriate to consider the Conference in its wider perspective, made possible by the numerous and long-distance tours that the delegates, either individuals or in parties, were able to make during their stay in Australia. Here was a vast expanse of land, much of it scrub and with large tracts of uncultivatable soil. Yet to-day approximately 127 million Australian sheep are producing more than 1,200 million lb. of greasy wool, 74 per cent of which is merino. This is merely a reflexion of the strength and endeavour of the Australian people who, as described in the Conference Handbook, "live in a dynamic economy". Since the introduction at the end of the eighteenth century of the first merinos into Australia and Tasmania, the land has been cleared and the pasture improved in order to raise such an immense number of the descendants of the original small stock. The arduous task of developing the refractory land was first achieved by the early settler, but to-day the Australian Mutual Provident Society is organizing and financing land clearance on a large scale. Terrain capable of feeding one-half or less sheep per acre is improved to levels of two or more per acre. This improved pasturage has been made possible by the work of the Commonwealth Scientific and Industrial Research Organization, which has investigated the vital questions of soil fertilization, selection of grasses, clovers, etc., the problems of metal deficiency in soils, and the many factors in the breeding and care of sheep.

Irrigation also presents a serious problem in a country where the rainfall is generally meagre and irregular. The delegates saw vast areas in Victoria and South Australia where there was serious flooding and where, in the summer months to come, the land will be dry and parched. Extensive schemes of irrigation and water conservation have been carried out or are nearing completion, and delegates had the opportunity of appreciating the magnitude of these schemes by visits to the Snowy Mountains and to dams under construction, such as that at Warragamba.

To-day there are stud farms where the merino stock is maintained, and the delegates were able to visit such studs near Deniliquin and those in the Macquarie Valley region in Tasmania, where a very pure strain of fine-woolled merinos is maintained. Research on genetics and growth of sheep by the Commonwealth Scientific and Industrial Research Organization has been most active. The occurrence of 'steely wool' and malnutrition of the sheep was traced to cobalt deficiency. The wide need for phosphate fertilization of the soil was demonstrated, and to-day problems such as 'staggers' due to *Phalaris tuberosa* are being investigated.

The people of Australia in general and the graziers in particular have come to appreciate the invaluable work of the Commonwealth Scientific and Industrial Research Organization, and the importance of the Conference to Australia was indicated by the presence of the Prime Minister and several colleagues at the inaugural dinner, and by the reception of all delegates by the Governor-General and Lady Slim at Canberra.

# SOIL MECHANICS, GEOLOGY AND CIVIL ENGINEERING

During the recent meeting at Bristol of the British Association, a most informative joint meeting between Section C (Geology) and Section G (Engineering) took the form of a symposium to discuss the interdependence of geology, civil engineering and the new science of soil mechanics. Mr. F. H. Edmunds, of the Geological Survey of Great Britain, introduced the discussion. He pointed out that the civil engineer, in order to make an appreciation of the likely reactions of the rocks to his activities, requires as full geological information as possible concerning a new site, particularly in regard to the physical characteristics of rocks as determined from small samples (their hardness, cohesion, porosity of the rock); the arrangement of rock masses and strata at an engineering site (whether they lie horizontally or are inclined or buckled or folded, etc.); and the potentialities of water storage in, and movement through, the rocks. Detailed geological information is more necessary to-day than in former years for two main reasons: through advances in technique and machinery, many civil engineering works of to-day are immensely larger and more complex than those of past days; and whereas the old engineers usually had the choice of site, present-day works often have to be constructed at sites imposed on the engineer. These may be on alluvial tracts, in coastal areas, or in other difficult situations where the ground is occupied by thick beds of unconsolidated material, in many instances saturated with water.

Up to thirty years ago, geological science had more or less ignored petrological studies of soft sediments. The physical characteristics of soft rocks and, in the case of clays, differences of behaviour relative to the variable factor of the amount of adsorbed water in them, had received scant notice; but these points are of vital importance to engineers. In the circumstances, engineers and physicists set out themselves to get information of the kind required. From their work has evolved the science of 'soil mechanics'.

The word 'soil' in this connexion connotes soft unconsolidated material irrespective of its thickness or of its depth below ground surface; it has but little connexion with the top several inches of the earth's crust associated with agriculture. Generally speaking, what the engineer calls 'soils' are the 'soft rocks' of geological terminology, for example, sand and clay. Their essential feature, however, is lack of consolidation.

Much of soil mechanics investigations is a matter of physics undertaken in the laboratory, but laboratory tests by themselves are incomplete. To obtain the fullest information from them the small samples used need to be related to the stratigraphy of the beds from which they are taken.

Mr. P. L. Capper, of University College, London, described the fundamentals of soil mechanics. Soil—used in the engineering sense—necessarily forms, in its natural condition, the foundation for all works of construction, except where these can be founded directly upon solid rock. It is also used extensively as a constructional material, for example, in embankments, dams and earth roads. In designing any members of an engineering structure, four points have to be considered: the load or external forces applied to the member; the internal forces and stresses set up in the member; the deformations produced; and the way in which failure will take place if the member is overloaded. The same applies to soil; but compared with other materials of construction, soil presents greater difficulties on account of its lack of uniformity and its susceptibility to changes in its properties arising from variation in the water content. Soil mechanics comprises three main divisions: mechanics of soils, that is, the loss of equilibrium induced by engineering work, stress distribution and movement of water in soil; site investigation and the testing of soil for the determination of the relevant properties; the application of the findings under the first two headings for civil engineering design and construction.

The first division of soil mechanics includes the study of the conditions of stability of masses of soil, the determination of the internal stresses set up in soil under the action of external and gravitational forces and study of the laws governing the movement of water in soil. As with other engineering materials, the solution of stability and stress-distribution problems in soil involves an application of statics combined with assumptions as to deformation characteristics such as elasticity or plasticity.

In deciding upon the depth to which an investigation should be carried out, the chief point is to estimate the depth of soil which will be appreciably affected by the applied loads, and this depends upon the extent of the loaded area. The concept of the bulb of pressure illustrates this principle. The most important soil properties from the engineer's point of view are compressibility, shear strength and permeability. The compressibility of soil, in the broadest sense of the word, may be defined as the relation between compressive deformation and the pressure producing it. The deformation may result from one or more of the following factors: it may be elastic, recoverable when the pressure is removed; plastic, due to plastic flow of material; or may result from consolidation or closer packing of the particles resulting from the expulsion of water. In clay soils the settlement due to consolidation may be of considerable magnitude but is a very gradual process.

The shear strength of soil is assumed to be made up of two components: intergranular friction and cohesion. Generally speaking, sands and gravels derive their strength almost entirely from friction, whereas in clay soils cohesion predominates.

Reviewing the rapid development of soil mechanics, it is seen that a vast amount of knowledge, theoretical and practical, has been accumulated in a comparatively short period of time. If this knowledge is to be used to the best advantage in civil engineering, careful study must be made of 'case history', that is, observation of engineering works during construction and while in ordinary use. Also, every opportunity should be taken of investigating thoroughly any failures which are attributable to the soil. Soil mechanics is not, and never can be, an exact science, and its successful application always calls for experience and common sense.

Two papers on direct applications of soil mechanics and geology to civil engineering followed, delivered respectively by Mr. A. H. Toms, of the Civil Engineer's Department, British Railways, Southern Region, and by Mr. D. F. C. Henry, of the University of Leeds.

It was not until about 1937–38 that the scientific study of the physical and engineering properties of soils was taken up by one or two selected civil engineers of British Railways with the view of obtaining better understanding of the many landslips and other soils problems with which British Railways are faced. In the case of landslips, calculation, taking into account the mechanics of the slipping masses, the water pressures and the resistances offered by the soil, now often enables a far more rational approach to be made to the remedial measures than was possible before the advent of the science of soil mechanics.

The biggest single landslip problem affecting British Railways is that of the coastal landslips of the Folkestone Warren, Kent. There the railway runs for two miles continuously across a great expanse of slipped chalk and Gault clay resulting not from a lubricated surface between the Chalk and the Gault as formerly assumed, but from shear failure of the Gault in its basement bed on top of the Lower Greensand. The Middle and Lower Chalk form cliffs rising to + 550 ft. O.D. behind the wide stretch of slipped ground, while the Gault underlies the whole of the affected area. In 1938, research was commenced into the nature of the slips, which were then once again beginning to threaten the stability of the railway. Test boreholes were sunk over a wide area down to depths of 300 ft. and many soil samples were extracted for visual inspection and special testing. In this work fossil identification and the recognition of stratigraphical horizons by the geologist proved of the utmost value in supplementing the information obtained from soil mechanics tests.

As a result of the research at the Warren, an extensive programme of stabilization works has been put in hand consisting of: (1) new sea walls farther out to sea, with filling behind protected by concrete slabs in order to provide toe weight on the foreshore; (2) drainage of water out of the slips by means of a new tunnel heading; (3) overhaul of all existing drainage headings and groynes; and (4) repair to old groynes and provision of new ones.

It has been found by experience that in many cases of substation buildings, signal boxes and bridges the design of the foundations is determined, not by the shear strength of the ground but by its consolidation settlement under the load. One of the most difficult problems which arises in connexion with the estimation of the probable settlement of structures is that in which a group of piles may be required to transmit the foundation load to a layer of soft compressible soil, the thickness of which is too great to permit the piles to penetrate to firmer material below. Nevertheless, it has proved possible to arrive at reasoned estimates of probable settlements in such cases, a typical one being that of proposed pile groups for new side spans to the Kingsferry Bridge over the Swale, where there is a great depth of soft alluvium overlying London Clay of varying strength.

Typical of the application of soil mechanics to the solution of tunnel stability problems is the case of Bo-peep Tunnel, Hastings. This double-lined tunnel passes through the Wadhurst Clay. A few years ago it was noticed that the tracks near the western end of the tunnel were rising, the side walls were closing in and houses over the top started to subside. Steps were taken at once to put temporary supports in the tunnel to arrest the movement. Very careful investigations revealed that the movements were due to shear failure of the ground in the side-wall footings. This had been brought about by very slow progressive softening of the ground under the tracks on account of the combined action of percolating water and the dynamic effects of rail traffic.

Following this instance, extensive soil mechanics investigations were made in both Hastings and Ore tunnels, and major strengthening works were put in hand.

Mr. Henry described some soil mechanics aspects of the design of pad, strip and raft foundations located on the surface of the ground or at a relatively shallow depth. Recent experimental investigations include those of Golder, who in 1941 carried out tests on axially loaded model footings ranging in size from 6 in. × 6 in. to 30 in. × 6 in. on the surface of clean dry river sand contained in a 3 ft. 6 in. × 3 ft. 6 in. × 14 in. deep box. Tests were also carried out on footings ranging from 3 in. × 3 in. to 18 in. × 3 in. on remoulded London Clay in a 2 ft. 6 in. × 1 ft. 8 in. × 8 in. deep box. Meyerhoff made some tests on footings on sand contained in a box with a glass front; the inside of the glass was smoked so that the movements of the grains under load were automatically scribed on the glass. In another series of tests, vertical and eccentric loads were applied on footings of various lengths and 1 in. wide on the surface of, and at shallow depths in, loose and medium Ham River sand and remoulded London Clay.

More experimental evidence based on larger footings tested on the surface of, and at a depth in, sand and clay and loaded with axial and eccentric loads is desirable. In planning tests, the elimination of restraint due to confinement of the soil is necessary, and the results must be carefully analysed in the light of what is known concerning the behaviour of soils under stress and the modes of failures of footings.

Mr. Henry concluded that the present position of soil mechanics aspects of foundation design is reasonably satisfactory. Where soil conditions are straightforward or the structure is not large—for example, a domestic house or a small retaining wall—then simple investigations of the site and tests coupled with elementary soil mechanics theories are sufficient for practical work. On the other hand, considerable practical experience and theoretical knowledge is required where soil conditions beneath projected important structures are complex, and the interpretations of investigations and recommendations are best placed in the hands of specialists.

The engineer will never be able to escape the fact that soil is the most variable material with which he has to deal, and even where a mass of soil is apparently of uniform type, its physical properties may vary considerably. Apart from general changes in physical properties which may occur across a site, there are innumerable local variations which would entail much work to determine and take into account directly. In suitable cases such local variations can be catered for in the design of important structures by means of a coefficient of variation, in the nature of a factor of safety, based on the magnitude and frequency of properties revealed by soil mechanics tests.

The symposium was attended by a large audience and admirably exemplified the value of joint meetings between sections, a feature that becomes yearly more desirable with the rapidly increasing degree of inter-digitation of the different sciences. Interest in the meeting was accentuated by the kindness of *Engineering* in providing pre-prints of the several papers, and of the Soil Mechanics Department of the University of Bristol in furnishing apparatus for purposes of demonstration. F. H. EDMUNDS

# LIGHTING AND VISION

THE discussion on lighting and vision in Section I (Physiology) of the British Association during the recent Bristol meeting was opened by four speakers whose papers dealt with some important aspects of the subject.

In the first paper, H. C. Weston, director of the Medical Research Council's Group for Research in Occupational Optics, gave a brief account of some of the studies of human responses to varieties of lighting that have been made in recent decades with the object of providing scientific knowledge as a basis for planning lighting, particularly for building interiors. A number of these studies which have influenced present concepts of good lighting practice have been made in Great Britain, under the ægis of the Medical Research Council and the Department for Scientific and Industrial Research. They were primarily prompted by concern for the welfare of people at work and for their occupational efficiency.

Thus, in the early twenties, Elton, Weston and Wyatt each studied the effects of lighting upon the performance of weavers, which was shown to vary with the amount of illumination available up to about 30 lm./ft.$^2$. Weston and Taylor varied the illumination provided for printing compositors, and found that the rate and accuracy of working was proportional to the logarithm of the illumination value up to a level of 25 lm./ft.$^2$. They also showed that if the lamps used were so placed as to be glaring, work was impeded and the effectiveness of a given value of illumination on the work was reduced.

McDermott determined the desirable illumination for the work of typists, and Adams studied the response of persons doing visually unexacting work under different conditions of lighting. By such field-studies in occupations, chosen because their visual demands seem typical of whole classes of occupations, it was hoped to determine a scale of values of illumination adequate on physiological and psychological grounds for diverse purposes. This is a lengthy and difficult procedure, and a more fundamental approach was suggested by Beuttell in 1933. Pointing out that the visibility of all objects depends on certain of their characteristics, chiefly their size, contrast and luminance, he proposed that the relations between these variables be ascertained experimentally, so that levels of illumination could be computed for any visual task the critical components of which could be measured.

Using a suitable series of standardized tasks, Weston determined these basic relations, and his data are widely used internationally in prescribing illumination for good visual performance. He has also shown the effect of age upon the performance of these visual tasks and how it varies with different levels of illumination.

A much studied aspect of lighting is glare. Current rules of practice for the avoidance of this evil are due largely to the experimental studies of Stiles and, more recently, of Hopkinson and others at the Building Research Station. Responses to a variety of other features of lighting have been and still are being studied scientifically. Although recent advances in knowledge of lighting requirements, as well as in lighting techniques, are being applied fairly extensively, there is no doubt that the present lighting of many homes, schools, hospitals, offices, factories and other places is poor; not very rarely it is almost incredibly bad.

The investigations described by W. R. Stevens, head of the Illumination Group, General Electric Company's Research Laboratories, Wembley, were made by Foxell and Stevens to explore the dependence of the capacity for seeing detail upon the luminance of the object looked at and the luminance of fields of different size surrounding the object. Lythgoe (1932) showed that, except at low values of test-object luminance, the visual acuity attainable is better when the surrounding field of view has a luminance not very much below that of the test-object than when this field has zero or almost zero luminance.

On the basis of this finding, it has been widely held that lighting for good seeing should brighten the whole apparent environment almost as much as it brightens the given object of attention. However, Lythgoe did not study the effect upon acuity of luminous surrounds of test-objects when the surrounds do not entirely fill the visual field. Foxell and Stevens have done this, and have also measured acuity at higher values of luminance than Lythgoe used. They made, altogether, about 100,000 observations, using a Landolt broken ring as test-object. The ring was presented in contrast with a central field subtending an angle of 0·5° at the eyes of the observers. The luminance of this field was varied up to a value of 10,000 ft. L. Visual acuity was measured with the remainder of the visual field dark and also when the small central field was surrounded with a more extensive bright field. Measurements were made using three such surrounds the angular subtense of which was, respectively, 6°, 38° and 120°. The effect of the bright surround was studied when its luminance was made either equal to or different from the luminance of the central field.

It was found that at low luminances of the central field, visual acuity was unaffected by the size and luminance of the surround except, as Lythgoe also found, that it was reduced when the surround luminance exceeded that of the detail to be detected. At all luminances of the central field exceeding 1 ft. L., the presence of a luminous surround improved acuity, and the best effect was observed when the central field and the surround were matched in luminance. The beneficial effect of a bright surround upon acuity was not significantly greater with surround sizes of 38° and 120° than with the 6° size. Although this comparatively small luminous surround suffices for the achievement of high acuity, in ordinary circumstances a general distribution of light is usually necessary in buildings because detail has to be seen in many positions.

Foxell and Stevens found that maximum acuity was reached at a central field luminance of about 1,000 ft. L., with a 6° surround of equal luminance. At higher levels of luminance and for all surround conditions, acuity decreased. Some experiments were also made with equal-luminance red–green combinations of test-object and central field to determine the acuity due to colour contrast. Quite high values of acuity were attained, but the maximum was inferior to that reached with a high-contrast neutral test-object.

In his contribution, dealing with some effects of filament and of fluorescent lighting on visual performance, Dr. W. F. Floyd, senior lecturer in physiology, Middlesex Hospital Medical School, London, presented the results of a number of tests applied to clerical workers subjected to these forms of lighting alternately. Among the questions which have been posed concerning fluorescent lighting, that of its efficiency as a visual stimulus is one to which an answer is of particular interest to large employers of labour, who must provide artificial lighting on a large scale. Another question is what, if any, is the effect of the usually unnoticeable cyclic variation in light output of fluorescent lamps ? Dr. Floyd's investigations were primarily intended to find an answer to these two questions.

Dr. Floyd first made an experiment with twenty-two persons of normal sight, who performed Weston's speed of visual discrimination test illuminated to 10 lm./ft.$^2$ alternately by filament lamps and by fluorescent lamps. The mean performance of the subjects under each illuminant did not differ significantly. Multiple tests of a similar kind were then performed by another group under 6 lm./ft.$^2$ of filament lighting and also under 6 lm./ft.$^2$ of fluorescent lighting; again there was no significant difference between the respective mean performances. In another experiment, seventeen persons were exposed to lighting which was automatically and instantaneously changed from filament to fluorescent at intervals of a few seconds. The filament lighting provided a fixed illumination, but the illumination given by the fluorescent lamps could be varied by the subjects, who were asked to match it to the filament lighting for 'equal comfort'. The mean level of fluorescent lighting chosen in this way was slightly higher than the control level, although the difference was physiologically insignificant.

So as to make a long-term comparison between filament and fluorescent lighting, three comparable groups of clerical workers carried out their normal daily work, interspersed with various tests of performance and of certain visual functions, for thirteen weeks under three forms of lighting. One group had filament lighting, another had fluorescent lighting operated by an a.c. power supply and the third group had d.c.-operated fluorescent lighting free from cyclic variations. The working illumination in each office was standardized at 12 lm./ft.$^2$. None of the tests applied to the three groups afforded any evidence that the three forms of lighting had different effects. Thus, from all these experiments, it appears that, for equal illumination, visual performance is just as good under fluorescent lighting, with or without 'flicker', as it is under filament lighting.

Discussing the lighting of streets and vehicles, J. G. Holmes, technical director of Holophane, Ltd., pointed out that its function is to give road users confidence in their visual impressions as trustworthy guides to action. In a suitable state of adaptation, the sensitivity of the eye to light is remarkable; but, while very low illumination may enable familiar objects to be recognized fairly quickly, the rapid recognition of unfamiliar and unexpected objects, which is often essential for the safety of road users at night, requires much better illumination. An almost instantaneous assessment of the quickly changing scene confronting both pedestrian and vehicle driver has to be made and suitable motor responses initiated.

Under modern conditions in busy traffic areas, there is a bewildering variety of lights, among which those intended to give vital information or warning to road users sometimes lack conspicuity or add to the general confusion. The essential information should be given clearly with the right emphasis, and misleading information must be avoided. The variety of suitable colours and shapes of road signal lights seems now to be exhausted, hence the recent recourse to flashing lights so as to achieve conspicuity.

There is a tendency to increase the power of lights to gain attention to them, but this device also increases dazzle. An example is the red 'stop' lights on numerous modern cars. Some of these are of 100 candelas or more, and this is out of proportion to the general level of street lighting. They appear with shattering suddenness, often only a few yards in front of a following vehicle driver, and they tend to promote irritation and strain rather than visual confidence. Flashing beacons at pedestrian crossings give a welcome and timely warning of the need for special care; but where a number of them are visible at multiple road junctions they are disconcerting if out of step. Flashing car-direction lights take longer to interpret than semaphore indicators.

Mr. Holmes directed attention to the importance of siting street lamps so as to define the direction of roads unambiguously and to reveal the presence of roundabouts and centre reservations. Although improved street lighting tends to encourage greater traffic density and somewhat higher vehicle speeds, there is some statistical evidence that the night accident-rate is reduced, and there is no doubt that it increases the confidence of road users. As to the question of yellow versus white headlamps, careful experiments have led to the conclusion that, for equal beam intensity, there is no significant difference in revealing power nor in estimates of glare, and it is not true that yellow light penetrates fog better than white.

The general discussion evoked by the papers which have been summarized was confined to the subjects of fluorescent and of street and vehicle lighting. The chairman, Dr. R. S. Creed, mentioned that difficulty in reading meniscus gauges under fluorescent lighting was within his knowledge, although this may have been due simply to misplacement of the lights. Dr. Floyd pointed out that lamps of different colour temperature give different colour-rendering and, occasionally, a critical contrast might be weakened by the light from one type of lamp although not by another. He had investigated a variety of complaints against fluorescent lighting, but they were often expressions of dissatisfaction with other conditions, or they were due to conditions of lighting not necessarily produced by using fluorescent lamps. In reply to speakers who asked whether ocular ill-effects resulted from long-term exposure to fluorescent lighting, Mr. Weston said that there is no evidence of this. There had been a few cases of ocular affections occurring soon after a change from filament to fluorescent lighting, and those affected had wrongly blamed the lighting; he mentioned one such case which was demonstrably due to a bacterial infection. When, as now, many changes to fluorescent lighting are taking place, it would be surprising if there were no merely coincidental occurrences of ocular troubles. From his own investigations, he could confirm Dr. Floyd's conclusion that complaints against fluorescent lighting often proved to have a different basis. Referring to flashing beacons at pedestrian crossings, a speaker thought it unfortunate that they do not adequately illuminate anyone using or waiting to use the crossing. As to the red 'stop' lights on cars, another speaker claimed that experiments have demonstrated that these should be of 50 candelas for seeing at a distance of 50 yards when a driver is dazzled by opposing headlights.

---

# GENETICS AND PLANT BREEDING

A JOINT session at Bristol of Sections K (Botany) and M (Agriculture) of the British Association was devoted to a symposium on "Genetics and Plant Breeding". The range of contributions to the symposium emphasized not only the scientific bases of present-day plant-breeding programmes, but also the dependence of advanced communities on a constant, integrated attack on those limiting factors to yield and quality which can be overcome by the genetical approach to crop improvement. A guaranteed standard of living, which advanced peoples have come to regard as a birthright, and which is now recognized as an international responsibility so far as the less-developed peoples are concerned, demands maximum efficiency from the germ plasm in food production. Not only must crop plants produce maximum yields at economic levels, but also quality, variety and long-term reliability of the material in the face of epidemics and environmental variations must also be among their attributes. The interaction of food production and soil fertility over large areas of the world presents grievous problems which can only be solved satisfactorily by escaping from an exhaustive form of monoculture to a rotational culture based on species of plants yet to be isolated from Nature's repertoire. If it is to continue to serve advanced communities, the science of plant-breeding has to respond quickly to human progress in all directions, in changes of dietary needs, in advances in agronomy, in farm mechanization as well as in the grading and processing of the final product.

Dr. D. Lewis, of the John Innes Horticultural Institution, Bayfordbury, in his opening paper, suggested how genetics, although unable to produce plants to order, can offer a systematic approach towards such problems and possibilities by initially 'blue printing' the foundation genotypes as well as outlining methods whereby a desired genetic architecture can be constructed stepwise. The limits to the construction of gene recombinations are frequently set by close linkage, involving gene effects with opposing or compensating functions. The eventual attainment of genotypes as near as possible to the ideal often depends on the breakdown of these linked units of inheritance. This problem is one with which crop-improvement projects are constantly being faced, and reliable methods such as a temporary passage through a tetraploid condition or the application of physical environmental stresses at meiosis might profitably be perfected to achieve an immediate and permanent release of undesirable gene combinations. Similarly, the breakdown of the natural breeding system of a species can often aid materially in releasing variability as well as in ensuring reliability of cropping. Thus in cherries, mutations induced by X-rays have yielded fully self-fertile genotypes which crop well even under adverse conditions for pollination by insects.

The importance of the part played by the breeding system in controlling variability and therefore in deciding the genetical approach to its improvement is nowhere better exemplified than in the genus *Rubus*, which was surveyed by Dr. G. M. Haskell (John Innes Horticultural Institution, Bayfordbury). Here apomixis is widespread, but in some instances variations in the mechanism allow of segregation and recombination among maternal chromosomes. Such sub-sexual processes give rise to greater variability than is often realized, and selection becomes possible. The segregation of quantitative characters within the sub-sexual apomict *R. nitidioides* (Merton Early) indicates that the improvement of economic characters such as earliness and intensity of prickles is possible, though the speed of selection will necessarily be slower than in fully sexual groups. Many apomictic species are also polyploids of various kinds, and a complete change to sexuality may reveal an unbalance characteristic of some polyploid groups. Thus in the *Eubatus* section of *Rubus*, broadly divisible into the mainly tetraploid group *Moriferi veri*, and the *Corylifolii*, which are largely pentaploid and are descended from the apomictic *R. caesius*, apomixis is widespread; whereas in the section *Idaeobatus*, consisting predominantly of diploid species, sexual reproduction is normal. The breeding behaviour of both inter- and intra-group hybrids is therefore often complicated, and only the most thorough study of joint segregations of groups of characters will ensure the detection of sexual progeny from the sub-sexuals and the apomicts. It is through such investigations on breeding behaviour and on the genomic constitution of species and varieties that the breeder can make full use of all the variability potential of his material.

Among the most helpful genetic concepts in plant breeding that have been developed in recent years are those elaborated by Prof. K. Mather in his studies on variability, in which variation is classified as free or potential. In homozygotes, all the variability is free and, discounting mutation, it is in a fixed state. If the breeding system allows, populations of homozygotes possessing maximum immediate fitness will be developed. Heterozygotes, however, contain potential variation which can only be freed at meiosis in sexual reproduction. Where the number of heterozygous loci is large, and where close linkage preserves gene combinations in a heterozygous condition, as it inevitably must in many cases, the problems of freeing the potential variation in heterozygous material become very real. Dr. A. J. Bateman (Christie Hospital and Holt Radium Institute, Manchester) emphasized that the upper limits of selection are governed by the methods that are used to realize the potential store of variability in heterozygotes. Using methods designed to exhaust the genetic potential, notions on the selection limits of certain characters in living organisms often have to be radically revised. This has been clearly demonstrated in laboratory experiments on *Drosophila* and the mouse, while in Nature it has become expensively obvious in another direction among the parasitic Basidiomycete fungi. Such laboratory and natural successes from new releases of variability underline the need for studying every aspect of plant-breeding procedure to ensure that crop improvement programmes shall not be allowed to rest on what well may turn out to be false selection limits.

One successful method of transcending selection limits has been the utilization of heterosis both in animals and plants. It is consistent with many aspects of the historical growth of science to find that immense benefits have followed the practical use of heterotic hybrids in food production, while we are still debating the nature of the precise genetic mechanism underlying the phenomenon. Mr. Watkin Williams (John Innes Horticultural Institution, Bayfordbury) developed a theme from which it could only be concluded that it was unnecessary and undesirable to partition heterosis into mutational euheterosis, balanced euheterosis, and luxuriance, after the scheme of evolutionists—notably Dobzhansky. Although it seems likely that the underlying genetic mechanisms controlling vigour are essentially the same in all these artificial categories, it does not follow that heterosis is always governed exclusively by any one mechanism in any given organism. Indeed, this is most unlikely, if only from analogy with the numerous mechanisms that are known to control discontinuous variation. The question of deciding between the two main theories of heterosis, namely, dominance with linkage as against the over-dominance theory, has hitherto presented an insoluble problem. However, the failure of certain selection procedures in the American hybrid maize programme indicates that the dominance hypothesis alone is insufficient to explain all the facts, while data on the biochemistry of heterozygotes, such as those of Pauling and Irwin, indicate the physiological mechanisms through which overdominance could operate. Thus an exclusive approach to heterosis is at present to be avoided, if maximum utilization is to be made of the various mechanisms which govern quantitative variation.

In no field of crop improvement is the basic approach so important as in selecting for resistance to disease. The breakdown in resistance which we have come to expect following the release of new varieties on a commercial scale has raised doubts in many minds as to whether the interplay between host and parasite can be settled in favour of the host. Dr. Lewis, from a survey of the literature, has concluded that genetic control seems more likely with insect pests than with fungal disease where chemical control appears to be more effective. An important consideration in this connexion was contained in a contribution by Dr. R. L. Knight (East Malling Research Station), in which it was suggested that the ease with which parasites form biological races may be correlated with a simple genetic mechanism controlling resistance in the host. Resistance based only on a few major genes may be more easily circumvented by a single mutation in the parasite. Complex resistances based on major genes, and reinforced by modifiers and polygenes introduced from a wide range of material, are on the contrary much less likely to be overcome by biological specialization in the parasite. The manipulation of complex resistances of this nature has been successfully accomplished with the cotton variety, Sudan Sakel, which is susceptible to attack by jassids. Here a bridging genotype had to be synthesized by back-crossing, to give a modified Sakel which in turn was used as the recurrent parent for the intensification of resistance through further transferences of polygenes affecting length and density of epidermal hairs. The scanning of a genus or of a species for sources of resistance involves the acquisition of a wide collection of genotypes from both wild and cultivated sources, and the maintenance of a large and expensive genetic museum of material. Nevertheless, in genera such as *Solanum* and *Gossypium*, where collections have been organized, valuable economic improvements have been achieved.

The regimentation of Nature's store of variability into collections for the ready use of the science of plant breeding needs to be interpreted in the last analysis as necessary organization for the benefit of humanity. Dr. G. D. H. Bell (Plant Breeding Institute, Cambridge) outlined the need for crop improvement in terms of the demands and responsibilities of the more advanced nations. World food production is now recognized as a world problem, and communities of people as they advance expend less and less of their energies on primary food production. Thus with vast new areas awaiting development on one hand, and shrinking acreages such as those of the British Isles demanding that maximum production be achieved at an economic level on the other, the plant breeder to-day is vital to survival. This sense of urgency has already been recognized both by sovereign countries and by international organizations such as the Food and Agriculture Organization and the Organization for European Economic Co-operation.

Notwithstanding such considerations, Dr. Bell emphasized that it is the need for the application of more scientific methods, and the great complexity of the problems to be solved, that have made necessary the provision of adequate and intelligent facilities for plant breeding. No longer can we afford to rely on a division of science into the pure and the applied, and wait for a piece of research to be completed in its appropriate pigeon-hole before further progress is attempted. Nor can we expect a science without scientists, and the training of a plant breeder presents yet another of those educational problems which most university curricula have so far failed to solve.

WATKIN WILLIAMS

# UNIVERSITY OF OXFORD SCHOOL OF FORESTRY

ON October 1, the University of Oxford School of Forestry celebrated its golden jubilee in the Imperial Forestry Institute, which has been its home since 1950, and in St. John's College, which has been very closely associated with it throughout the fifty years of its existence. When the Royal Indian Engineering College at Coopers Hill (near Windsor) closed in 1905, training for the Indian Forest Service which had been given there since 1888 was transferred to Oxford, temporary accommodation having been secured to serve until the building promised by St. John's was ready. The director, Dr. (afterwards Sir William) Schlich, and his assistant W. R. Fisher brought over the current class of twelve probationers and thus opened the first university forestry school in Britain (or indeed the British Empire), though Edinburgh already had a lecturer in forestry. The senior of this group, A. E. Osmaston, officiated at the planting of a jubilee oak tree at the recent celebrations. This was done in Bagley Wood, which has been continuously available to the School through the generosity of St. John's, the owner of the wood for four centuries. Mr. Osmaston is one of a famous forestry family of which seven members are serving or have served in the Forest Services of India, Britain and the Colonies ; three were present on this occasion. He was assisted by one of the present students, and a gathering of about 130 persons, nearly all former students or members of the staff, witnessed the ceremony.

The jubilee address was delivered by Sir Harold Glover, one of the first students to read forestry in Oxford, his year being headed by the late Lord Robinson, sometime chairman of the Forestry Commission. Many of that year took degrees in natural sciences, as well as the Forestry Diploma. Sir Harold joined the Indian Forest Service, Oxford having been for some years the only training centre for Indian Service probationers ; between 1907 and 1932, when recruitment in the United Kingdom ceased, 213 out of the total intake of 306 had passed through the School. The last five inspectors-general in India have been Oxford graduates, including the present holder of that important post.

In 1924, the School was strengthened by the establishment of the Imperial Forestry Institute to provide a centre for higher education and research for those parts of the Empire which needed such facilities : though the Institute was in no sense a part of the School, many facilities such as the library were shared, and members of the Institute staff undertook some of the teaching. The two organizations were amalgamated in 1938 to form the University Department of Forestry. In the early years, only a diploma was awarded on the work of the two or three years the course covered, but a pass degree was granted in 1918, and finally an honours degree in 1944.

The School has provided 144 recruits to the Colonial Forest Service, and since the opening of the Institute, practically all members of that Service have attended postgraduate courses in Oxford. The proportion of the officers of the United Kingdom Forestry Commission trained at Oxford has been lower, but forty-four are serving at present, and the Commission's research staff worked at Oxford before the research station at Alice Holt was established.

A lunch was given in St. John's College, the speaker being Sir Henry Beresford-Peirse, deputy director-general of the Forestry Commission. He made particular reference to the very wide range of subjects covered in a university forestry course, giving it an educational value much beyond a technical training.

The average number of students over the past three years has been fifty-eight, and the number graduating twelve. There are at present students from the United Kingdom, Canada, New Zealand, South Africa, India, Pakistan, Burma, Ceylon and several Colonies. The staff now consists of the professor, one reader, sixteen demonstrators, twenty technical assistants, twelve secretarial and librarian employees and six others, and the annual expenditure approximates £50,000.

H. G. CHAMPION

# OBITUARIES

## Prof. H. K. Mookerjee

THE death occurred very suddenly on August 18 of Prof. H. K. Mookerjee, professor and head of the Department of Zoology of the University of Calcutta. Born in 1898, Mookerjee's undergraduate days were spent in the Presidency College, Calcutta. He won the University Gold Medal in zoology in 1924, and joined the University as assistant lecturer in 1925. As the Guruprasanna Ghose Scholar, Mookerjee went to London in 1926, and worked in the Imperial College of Science and Technology under the late Prof. E. W. MacBride. His work on the development of the vertebral column attracted considerable attention. He was Sara Marshal Scholar in the Imperial College during 1927–28, and Ghose Travelling Fellow of the University of Calcutta during 1928–29. He was awarded the D.Sc. of the University of London in 1930. He rejoined the University of Calcutta on his return, and in 1933 became the University professor of zoology, which post he filled with great credit until the end of his life.

Prof. H. K. Mookerjee's important contribution in the field of embryology and evolution was based on the study of development of the axial skeleton of practically all groups of the chordates starting from *Balanoglossus* right up to man. He pointed out further that the centrum of all the chordates is formed in the same manner according to a basic plan ; in the development of the vertebral centrum of all the chordates, from *Amphioxus* up to the mammals, only notochord, chord sheath, and the pericordal tube formed around the latter, take part, according to Mookerjee, but not the arch-bases or other elements claimed previously. Besides this hypothesis, Mookerjee also pointed out the many characteristic changes that take place in a non-plastic organ like the vertebral column along with change of environment. Very recently, he had shown that the so-called notochord of *Balanoglossus* is really the true dorsal nerve cord with a definite neurocœl. He utilized this finding to draw up the affinity of the *Balanoglossus* in a recent paper.

Prof. Mookerjee was elected president of the Zoology Section of the Indian Science Congress in 1936 and was elected a Fellow of the National Institute of Sciences of India in 1939. He was associated with various learned bodies and connected with different Indian universities in various capacities. He acted as a secretary of the Asiatic Society in the Natural History Section and was the founder-president of the Zoological Society of Bengal. He was an important member of the senate and syndicate of the University of Calcutta.

Prof. Mookerjee was responsible for initiating fishery research in the University, and himself made notable contributions to the life-history of freshwater fishes of Bengal. He was admired and respected by all who came in contact with him. He leaves his mother, wife and one son and three daughters and a host of friends and admirers who mourn his loss.

S. R. Bose

## Mr. Howard Evans

The death occurred, suddenly, on September 11, of Mr. Howard Evans, superintendent of the Laboratory of the Development and Research Department of the Mond Nickel Co., Ltd.

Mr. Evans was born in 1907. He was educated at the Grammar School, Penistone, after which he was for five years junior chemist at the Penistone Iron and Steel Works of Cammell Laird and Co., Ltd. During this period he was a student at the University of Sheffield, and graduated A.Met. with the award of the Mappin Medal and Premium in 1930. From 1930 until 1938 he was employed as research metallurgist in the Physics Section of the Research Department of the Metropolitan-Vickers Electrical Co., Ltd., Manchester, except for one year, when he was working on iron–aluminium alloys on a George Senior fellowship at the University of Sheffield. It was during this period that he co-operated with Dr. C. Sykes in his classic work on order/disorder transformations.

In 1938, Mr. Evans joined the Development and Research Department of the Mond Nickel Co., Ltd., as a research metallurgist in the Birmingham Laboratory, under Dr. L. B. Pfeil. After a period of activity on various research projects relating to steel, including work on steel castings and on temper brittleness, he became closely associated with war-time investigations undertaken by that company on behalf of government departments. To all this work he brought outstanding energy and enthusiasm, a meticulous attention to detail and insistence on an excellence of performance from which he would never depart.

In 1945 he was appointed principal assistant to the superintendent, and in May 1954 superintendent of the Laboratory. In these capacities he was connected with a wide variety of research projects in both the ferrous and non-ferrous fields, and his indefatigable zeal was a constant inspiration to those with whom he worked.

Mr. Evans was elected a Fellow of the Institution of Metallurgists in 1946 and was a member of many metallurgical organizations, to which he presented numerous technical papers. During the year 1954–55 he was president of the Birmingham Metallurgical Society.

A notable feature of Mr. Evans's activities was his sincere interest in the training and education of junior members of his staff, many of whom have profited by his sympathetic guidance and encouragement when embarking upon a metallurgical career. His interest in technical education led him to undertake part-time lecturing for some years at the Birmingham College of Technology, despite his very heavy duties in other fields. He joined with typical wholeheartedness and no little skill in the recreational life of his colleagues and continued to take part in many of their sporting activities right up to the time of his death.

In all the many circles in which he moved, Howard Evans will long be remembered for his enthusiasm, initiative and ability to get things done.

W. Steven

# NEWS and VIEWS

### Editor of *Science* and *The Scientific Monthly*: Prof. G. DuShane

Prof. Graham DuShane, of Stanford University, has been appointed editor of *Science* and *The Scientific Monthly*, the two journals published by the American Association for the Advancement of Science. Prof. DuShane, who is forty-five years old, took his Ph.D. degree at Yale in 1934 for embryological work and then did two years of research in the University of Iowa and in Stanford University. The following ten years were spent in the University of Chicago, teaching in the Department of Zoology and carrying out research on problems of amphibian morphogenesis. In 1946 he moved to Stanford University where, in addition to his work in embryology, he devoted himself to the development of the University's programme in general biology and gave freely of his services for editorial consultation and faculty committee activities and as the president of the Stanford chapter of the American Association of University Professors. Prof. DuShane goes to the editorship of *Science* and *The Scientific Monthly* initially on the basis of a year's leave of absence from Stanford. The breadth of his scientific knowledge, his facility in writing and editing, and his interest in the accurate communication of the findings and conditions of science are good auguries for the future of the Association's journals.

### United Kingdom Agricultural and Food Representative in the United States: Mr. O. G. Williams

Mr. Owen G. Williams, provincial grassland officer for the East Midland Province of the National Agricultural Advisory Service, has been appointed to the new post of United Kingdom assistant agricultural and food attaché in Washington, D.C. The post of agricultural adviser (technical) has been discontinued, but its main functions will be incorporated in the new assistant attaché post. Mr. N. F. McCann, the former agricultural adviser (technical), will take up a new appointment as deputy director of the

National Agricultural Advisory Service in the Yorkshire and Lancashire Province. Mr. Williams, who is forty-three, graduated in agricultural botany from the University College of North Wales, Bangor, in 1941. Before his university studies he had considerable practical experience, including eight years on his father's mixed farm in the Conway Valley and a year as manager of a large dairy farm. He joined the Ministry of Agriculture and Fisheries in 1942, becoming two years later a technical development officer for the county of Buckinghamshire. Mr. Williams has taken particular interest in the development of herbage seed growing in Buckinghamshire and the East Midlands, and has been a member of the Management Committee and vice-chairman of the Certifying Committee of the Lincolnshire Seed Growers' Association. He has also been a member of various young farmers' clubs advisory committees and has lectured frequently to farmers' clubs and societies. He was one of the official United Kingdom delegates to both the Fifth International Grassland Congress held in Holland in 1949 and the Sixth Congress held in the United States in 1952, and at the latter he afterwards toured extensively in the Middle West, visiting farms and research stations.

## Royal Aeronautical Society: Mr. E. T. Jones, C.B., O.B.E.

Mr. E. T. Jones, principal director of scientific research (air), Ministry of Supply, has been elected president of the Royal Aeronautical Society for the year 1956–57 and will take office at the annual general meeting of the society, to be held on May 10, 1956. Mr. Jones, who is fifty-eight, was a pilot and flying instructor in the R.F.C./R.A.F. during 1915–19, and then graduated from the University of Liverpool. During 1923–30 he was with the Aerodynamics Department, Royal Aircraft Establishment, and for eight years was with the Marine Aircraft Experimental Establishment, Felixstowe. During the Second World War he was chief superintendent of the Aeroplane and Armament Experimental Establishment, Boscombe Down; in 1947 he was appointed director of instrument research and development at the Ministry of Supply, and was promoted to his present position at the Ministry in 1949. Mr. Jones was created an O.B.E. in 1942 and C.B. in 1953.

## American Academy of Arts and Sciences: Award of Francis Amory Prizes

Francis Amory prizes of 3,500 dollars each, for the invention or discovery of measures for the relief or cure of diseases affecting the genito-urinary system, have been awarded by the American Academy of Arts and Sciences as follows: Frederic E. B. Foley, Lowry Medical Arts Building, St. Paul, Minnesota, for outstanding inventive and surgical genius in the treatment of those afflicted with urological disease; Choh Hao Li, University of California, Berkeley, California, for his work on the relation of the anterior pituitary hormones to the maintenance and functioning of the human reproductive organs; T. R. R. Mann, Molteno Institute, University of Cambridge, for his basic contributions to the biochemistry of reproductive functions providing basic data stimulating research and clinical progress; Terence J. Millin, Queen's Gate Clinic, London, for his contribution to surgery; Warren O. Nelson, College of Medicine, State University of Iowa, for his studies of the structural relationships of the male sex organs and of the factors that determine the functional activities of their components; Frederick J. Wallace, American Cystoscope Makers, Inc., New York, for his co-operation with the urological profession in developing diagnostic and therapeutic instruments which have contributed materially to the technical advances in this specialty; Lawson Wilkins, Johns Hopkins University, Baltimore, Maryland, in recognition of his contributions to fundamental knowledge of the growth and development of secondary sex characteristics in man and his application of the adrenal cortical hormone to their management and treatment.

## New Headquarters for the Institute of Biology

The Institute of Biology, having spent the first five years of its existence in rooms at Tavistock House, has moved to new premises at 41 Queen's Gate, London, S.W.7 (Tel.: Western 2229). The new rooms are in the house of the Royal Entomological Society, and the meeting room of this Society is to be made available to the Institute of Biology for certain of its meetings. The removal marks a stage in the development of the Institute, which has now achieved a membership of twelve hundred full members, seventy probationer members and three hundred student members. The new headquarters will provide facilities not previously available to members. In particular, a members' room has been provided in which members will be able to meet friends, conduct interviews and hold small discussion groups. A telephone and ample space for writing and reading will be provided. A selection of works of reference will be available, and there will be a frequently changed display of recent books on biological subjects, maintained by a leading scientific bookseller. While it is not proposed to attempt to build up a comprehensive library because of the existence of the neighbouring libraries dealing with various branches of biology, the Institute may establish a collection of books on the broader aspects of biology which will include copies of the classic works of the past. It is hoped that the new rooms will be found useful, possibly in different ways, by members from the Colonies spending long leaves in Britain, by the many members in the London area who have no access to similar facilities in central London and by those from other parts of Britain paying brief visits to London.

## Television Transmitter at Meldrum, Aberdeenshire

The opening on October 12 of a new B.B.C. medium-power transmitting station at Meldrum, Aberdeenshire, brings television within the reach of about half a million people living in the north-east corner of Scotland, south of the Moray Firth. This transmitter replaces the temporary low-power transmitter at Redmoss, Aberdeen, the useful service-area of which did not extend much beyond the city boundaries. The 5-kW. vision and 1·25-kW. sound transmitters, manufactured by Marconi's Wireless Telegraph Co., Ltd., feed a three-stack 'batwing' aerial mounted at the top of a 500-ft. steel mast. The mast and station are situated on a hilltop, so that the aerial is about 1,300 ft. above sea-level. About half-way up the mast is an eight-tier slotted aerial from which the B.B.C. Home, Light and Third programmes will be radiated when frequency-modulated very-high-frequency transmitters are installed early in

1956. No studios are provided at the station. The video signal from the Kirk O' Shotts transmitter is picked up at a Post Office receiving station at Cupar and relayed to Old Meldrum via a two-stage microwave link. Additional microwave aerials and receivers are available for use with outside broadcast units. The audio signal comes over Post Office landlines with some inevitable loss of the higher audio frequencies. A low-power (500 W. vision, 125 W. sound) transmitter, manufactured by Standard Telephones and Cables, Ltd., is installed for use should the main transmitter fail. It is supplied from a diesel alternator. The main transmitter can draw its power from either of two independent 11-kV. ring mains operated by the North of Scotland Hydro-Electric Board, and the customary stand-by diesel alternator has been dispensed with.

## Patent Office Library Centenary

The Patent Office Library, at 25 Southampton Buildings, Chancery Lane, London, W.C.2, has just celebrated its centenary year with an exhibition of literature illustrating the development of the industrial arts through the century of its existence. The exhibition showed industrial development by decades and included specifications of basic inventions, manufacturers' catalogues and scientific and technical periodicals which appeared in each period of the century covered. The material displayed was an attempt to demonstrate the resources of the Library and to illustrate the importance of patented inventions in the foundation of great industries. Some original examples of manufactured products, now widely known and used, were displayed as a focus to the exhibition of literature. A special tribute was paid in the exhibition to Bennet Woodcroft, F.R.S., the first clerk to the Commissioners of Patents and founder of the Library.

## Documentation of Spectra by Punched Cards

The documentation of new scientific data so that it remains within readable bounds presents a growing problem, and the difficulties are especially acute in those fields of pure and applied research where the solution of a particular problem demands a preliminary exhaustive search in the literature for physico-chemical reference data. For example, there is a recognized urgent need for spectral data in a compact form. This applies especially to infra-red and Raman data for use in physical or organic chemistry and for analysis, all the more since lack of space and costs now prevent full publication of such material in the scientific journals. A joint Anglo-German scheme for the documentation of molecular spectra, recently announced by Butterworths Scientific Publications (88 Kingsway, London, W.C.2) and Verlag Chemie (Weinheim/Bergstrasse), is therefore welcome news for many academic and industrial laboratories. The spectra of pure compounds, and of other technological products, will be provided on punched cards, with much other structural and spectral information. A detailed code which applies to the punched holes has been designed so that the cards can be used to provide the answers to a wide variety of questions which often occur in research. The spectral cards are also linked to a current literature survey, which adds to their intrinsic value. Details of the scheme, which is expected to begin in 1956 with about two thousand cards annually, can be obtained from the publishers.

## Hair Embroidery in Siberia and North America

No. 7 in the series of Occasional Papers on Technology of the Pitt Rivers Museum, Oxford, deals with the subject of "Hair Embroidery in Siberia and North America" (pp. 83+16 plates; from the Museum, 1955; 15s.). Mr. Geoffrey Turner, who has been closely associated with the Museum for many years, has made a deep study of the North American Indians and their material culture, and no one in Great Britain is better at placing a given specimen. Moose and reindeer hair embroidery are often confused with porcupine quill work, and Mr. Turner shows how they may be distinguished, also explaining how the various techniques are carried out and where they are found. In addition, he outlines what is known of the historical background, showing the effect of French influence on the development of the craft in North America. The paper will be indispensable to all museum curators who have North American or similar Asiatic material under their care, and it is to be hoped that more of Mr. Turner's learning will be published in future numbers of the series.

## Illuminating Engineering Society

At the first meeting of the Illuminating Engineering Society for the 1955–56 session, Mr. A. G. Higgins, assistant secretary of the Institution of Gas Engineers, took office as president. Mr. Higgins formerly held a number of positions with the South Metropolitan Gas Co., including that of outdoor lighting superintendent.

The following awards have been made for papers presented to the Society during the past year: *Leon Gaster Memorial Premium*, to Dr. W. E. Harper (Plastics Division, Imperial Chemical Industries, Ltd.) and Mr. A. G. Palmer (North Thames Gas Board) for their paper entitled "Lighting of Hazardous and Corrosive Locations in Industrial Plants"; *Silver Jubilee Commemoration Award*, to Mr. K. R. Ackerman (British Broadcasting Corporation) for his contributions to lighting design and brightness patterns.

## Royal Institution: Lectures

The programme of lectures at the Royal Institution up to Christmas includes seven Friday Evening Discourses, beginning October 28, as follows: Sir Edward Salisbury (director of the Royal Botanic Gardens, Kew), fruit and seed production; Sir Graham Sutton (director of the Meteorological Office), weather forecasting—the future outlook; Dorothy L. Sayers (author), 'Œdipus Simplex'—freedom and fate in folklore and fiction; Dr. C. F. A. Pantin (reader in zoology, University of Cambridge), the primitive nervous system; Dr. B. F. J. Schonland (deputy director of the Atomic Energy Research Establishment, Harwell), lightning and the long electric spark; E. J. H. Corner (lecturer in botany, University of Cambridge), botanical collecting with monkeys; and Sir Lawrence Bragg (resident professor and director of the Laboratories at the Royal Institution), the discovery of useful electricity. In addition to the Discourses, Prof. J. B. S. Haldane (Weldon professor of biometry, University College, London) will deliver the Woodhull Lecture on October 27 at 6 p.m., speaking on "The Prospects for Eugenics". R. H. Macmillan (lecturerer in engineering, University of Cambridge) will give four lectures on Tuesdays (at 6 p.m.) beginning October 25, on the subject of automatic control and production. On November 3, 10 and 17 (at 6 p.m.), Dr. R. C. Sutcliffe (deputy director of the Meteorological

Office) will give three lectures on large-scale weather processes. Both these sets of afternoon lectures are open to the public (2*s.* 6*d.* per lecture). The Christmas Lectures will be given by Prof. H. W. Melville, Mason professor of chemistry in the University of Birmingham, who will speak on "Big Molecules". Lectures, illustrated by experiments, have also been arranged for school children, and refresher courses for science teachers will be given. Details of these have been sent to education authorities in the London area and it is hoped that this new venture in science teaching, which Sir Lawrence Bragg started so successfully last year, will become an important part of the Royal Institution's work.

### Iron and Steel Institute

The eighth Hatfield Memorial Lecture of the Iron and Steel Institute will be given on October 7, at 6.30 p.m., in the Firth Hall of the University of Sheffield by Dr. E. C. Bain, vice-president, research and technology, of the United States Steel Corporation, his subject being "Trends in Metallurgical Research in the United States". Admission will be by ticket only, obtainable from the Registrar, University, Sheffield 10. A half-day meeting of the Iron and Steel Engineers Group will be held at the Engineers' Club, Manchester, on the morning of October 20, in connexion with the National Fuel Efficiency Exhibition; Dr. W. S. Walker (Round Oak Steel Works, Ltd.) will present a paper on "Fuel Efficiency in the Iron and Steel Industry". The autumn general meeting of the Institute will be held during November 16–17, at the offices of the Institute, 4 Grosvenor Gardens, London, S.W.1.

### Commonwealth Fund Fellowships for Advanced Study and Travel in the United States

A number of Commonwealth Fund fellowships are again being offered by the Commonwealth Fund of New York to British subjects, for study and travel in the United States. All expenses of travel, study and living will be met, with some adjustment of stipends for married men. The fellowships, which are open to British men and women who are not normally resident in or near the Americas and who have not previously worked or studied for more than a few months in the United States, are offered annually in six categories as follows. *General:* twenty fellowships to graduates of a university in Great Britain or Northern Ireland; candidates must be available in London for interview in March 1956; age, 23–32; tenure, 12–21 months; applications by December 15. *Home Civil Service:* five fellowships to permanent members, in the higher ranks of the Civil Service in Great Britain, three for the administrative grades and two for the scientific and professional grades; age, preferably less than 40; tenure, 9–15 months; applications by December 10. *Australian and New Zealand Civil Services:* five fellowships to Civil servants in the Governments of Australia and New Zealand; age, less than 40; tenure, 9–15 months; applications by November 1. *Oversea Civil Service:* two fellowships to Civil servants in the Governments of British Colonies, Protectorates and Trust Territories; age, less than 40; tenure, 9–15 months; applications by November 18. *Journalism:* three fellowships to journalists practising in the United Kingdom and engaged on the opinion-making or broadly editorial side of their profession; age, 23–35; tenure, 9–15 months; applications by December 31. *American Studies:* four fellowships to faculty members appointed to or holding posts in American studies in universities in the United Kingdom; candidates to be nominated by their universities; tenure, 4–15 months (these fellowships are not limited by previous study in the United States). Application forms and further information can be obtained through British universities or Government departments, or from the Warden, Harkness House, 35 Portman Square, London, W.1.

### Announcements

Prof. R. C. Garry, regius professor of physiology in the University of Glasgow, and Mr. H. J. Seddon, director of studies in the Institute of Orthopædics, University of London, and clinical director of the Royal National Orthopædic Hospital, London, have been appointed members of the Medical Research Council.

On the occasion of a visit to Great Britain by Prof. J. Heyrovský, of Prague, an advanced course on polarography will be given at the Royal Technical College, Salford, Lancs, during November 18–19. A number of lectures will be given, including two by Prof. Heyrovský; and there will be a demonstration of apparatus. The fee for the course is one guinea. Further information can be obtained from the Head of the Department of Chemistry and Applied Chemistry at the College.

Mr. W. H. Rutherford has been appointed assistant secretary of the Royal Society of Edinburgh in succession to Mr. G. A. Stewart (see *Nature*, October 8, p. 675). Mr. Rutherford, who has been on the staff of the Society since 1940, has served as Mr. Stewart's deputy since 1948. Educated at the High School of Dundee, he was elected a fellow of the Society of Secretaries in 1951, an associate of the Corporation of Secretaries in 1954, and is a member of the Royal Institute of Public Administration.

Prof. F. J. Llewellyn, professor of chemistry in Auckland University College, New Zealand, and formerly senior lecturer in chemistry at Birkbeck College, London, and I.C.I. Research Fellow in the University of Birmingham, has been appointed rector of Canterbury University College, Christchurch, in the University of New Zealand.

Dr. F. H. K. Green has resigned from the secretaryship of the (European) Scientific Advisory Committee of the Lady Tata Memorial Trust, which he has held since 1934, on his appointment as scientific secretary of the Wellcome Trust. He will be succeeded by Dr. David Galton, of the Chester Beatty Research Institute, Fulham Road, London, S.W.3.

At the October meeting of the Board of the Institute of Physics, it was unanimously resolved to record in the minutes that it had noted that the British physicists, under the leadership of the president (Sir John Cockcroft), played a prominent part in the recent United Nations Conference on "The Peaceful Uses of Atomic Energy", and was happy to see this further contribution to one of the Institute's principal objects, namely, the advancement and diffusion of a knowledge of physics, pure and applied.

Reference was made in *Nature* of August 13, p. 297, to a paper on the drying of skins, published in *Colonial Plant and Animal Products.* The authors of this paper were Dr. M. H. French and Dr. R. L. Sykes; we regret that Dr. French's name was omitted.

# CINEMATOGRAPHY IN SCIENTIFIC RESEARCH

PROGRESS in scientific research depends on precision instruments, because accurate quantitative data alone can form the ultimate basis of new discoveries. Although infinitely versatile, our human sense organs are very limited when accurate measurements are needed, be they of size, or length or of weight. The invention of the microscope, the micrometer and of the chemical balance have each opened large fields of research, and their accurate measurements have greatly advanced biology, engineering and chemistry. Without such instruments, and the ciné camera is one of them, scientific research would scarcely have progressed beyond the speculative and descriptive stage. To demonstrate the latest results achieved by scientific cinematography, the Scientific and Technical Group of the Royal Photographic Society arranged a special morning session on September 3 at the British Association meeting in Bristol. In spite of many other attractions, it was extremely well attended, and the audience numbered more than three hundred.

The meeting was opened by R. J. Hercock, chairman of the Scientific and Technical Group, who introduced the programme, and by Prof. N. F. Mott, who took the chair during the morning. Prof. Mott was of the opinion that research films are well suited to bring together scientific workers from many different disciplines, and that this is one of the main functions of the British Association. He was followed by Dr. A. R. Michaelis, who had been responsible for the organization of this session. Dr. Michaelis gave a brief outline of the history of the subject, of E. J. Marey's classical contribution and his insistence on the quantitative nature of all scientific cinematography, which he hoped would be stressed by all the other speakers. He mentioned the many cinematographic techniques which have been used in scientific research and gave a few classical examples of their applications in different fields.

The use of high-speed cinematography in physical and engineering research was the subject of W. D. Chesterman's (Royal Naval Scientific Service) paper and research film. A wide range of problems was shown on the screen, particularly noteworthy being underwater sequences of cavitation phenomena, partly recorded on models in hydrodynamic flow channels and partly recorded in the open sea. Spark cinematography at frequencies up to 100,000 frames/sec. was demonstrated in ballistic research work and showed in detail the impact of projectiles on armour plating. Mr. Chesterman concluded with a plea for the wider use of underwater cinematography by marine biologists, who might well use this established technique for the study and recording of their subjects in natural surroundings.

An example of the use of high-speed cinematography in industrial research was presented by D. J. Dearnley (Central Research Establishment I, National Coal Board). Froth flotation of fine-coal particles was cinematographically recorded at 2,500 frames/sec. in order to elucidate the mechanism and efficiency of grain attachment to air bubbles. A field-splitting optical system was developed in order to record each bubble simultaneously from two directions at right angles, and from the resulting research film, received with applause at the meeting, it proved possible to measure collection efficiency and contact times as well as to plot the trajectories of particles and bubbles.

The most outstanding research film shown at the meeting was the one dealing with the behaviour of living cells in tissue culture, presented by E. J. Ambrose (Chester Beatty Research Institute, London) and recorded in collaboration with M. Abercrombie (University College, London). Combining the new technique of Smith (Baker) interference microscopy with time-lapse cinemicrography, Dr. Ambrose was able to show a colour film which left a deep impression on all who saw it and which was received with much applause. The advantage of this new technique was the demonstration of changes in thickness of cells, shown by marked colour changes, and thus providing an extra dimension in the depth of the recorded image. In the film, the behaviour of normal and cancer cells was contrasted, showing that, when two normal cells make contact, adhesions occur on their surfaces which do not take place in the case of tumour cells. Particularly outstanding was the record of the behaviour of cancer cells in the presence of ribonuclease; this enzyme stimulated the free movements of the cancer cells even further and led to their death through over-digestion of the enzyme.

High-speed cinematography through the microscope, a rare and extremely difficult research technique, was demonstrated with three examples by R. McV. Weston (Simpl, Ltd.). After explaining the technical problems of the technique, Mr. Weston showed its use for recording the movement of mercury in a clinical thermometer, for examining the lever escapement of a watch and for the discharge of elaters and spores from a liverwort. The first two films showed hitherto unknown defects, and the third allowed quantitative evaluation by Prof. C. T. Ingold (Birkbeck College, London), for whom it was taken. In the absence of Dr. J. S. Courtney-Pratt in the United States, Mr. D. P. C. Thackeray (Research Laboratory on the Physics and Chemistry of Surfaces, Cambridge) presented a brief paper and a research film made by the Courtney-Pratt image-sampling technique; the subject of the film was the explosion of single crystals.

X-ray cinematography, both of the direct and the indirect method, was shown by G. E. H. Foxon (Biology Department, Guy's Hospital Medical School, London); the ingenious use of 'Meccano' gears was greatly admired in a film more devoted perhaps to an exposition of technique than of results. J. Underwood (G.K.N. Group Research Laboratory) gave the last paper, describing further examples of the use of high-speed cinematography in industrial research: his first high-speed film showed the passage of liquid in a heat-exchanger model; his second the initiation of a welding arc under an argon shield by a condenser discharge; and his third, taken at 5,000 frames/sec., allowed the determination of the acceleration characteristics of the blades of a flying shear. Altogether, thirteen films were shown at the meeting, which concluded with excerpts from the American research film, "Color Motion Pictures of the Whole Sky".

Four German research films which had been specially sent over for this meeting were projected two days later during the general festival of scientific films. Two of these were "Netzbau der Kreuzspinne" and "Pervitinwirkung bei der Kreuzspinne"; both were made by Prof. H. M. Peters (Zoological Institute, University of Tübingen). The second of these two was particularly noteworthy, as it allowed the quantitative evaluation of the action of benzidrine on the spider *Aranea diadema*; this was achieved by plotting against time the intervals along the radial threads of the web. "Biologie des Hamsters", Parts 1 and 2, were produced by Dr. I. Eibl-Eibesfeldt (Department of Animal Behaviour, Max-Planck Institute for Marine Biology, Buldern, Westphalia) and showed some remarkable instances of mating behaviour of hamsters as well as of their young. These four films were lent by the Institut für den wissenschaftlichen Film, Göttingen, through the courtesy of its director, Dr. G. Wolf.

There can be no doubt that this first collective presentation of research films from many disciplines at a meeting of the British Association was a great success, as the frequent and often lengthy applause by the audience amply demonstrated. The hope can only be reiterated in this article that, at the meeting next year in Sheffield of the British Association, all those who have made research films in the meantime will use the opportunity to present their results; the films should be submitted to either the Scientific and Technical Group of the Royal Photographic Society or to the Scientific Film Committee of the British Association.

A. R. MICHAELIS

---

# RADIOCARBON DATING

## CONFERENCE IN CAMBRIDGE

THE second conference on radiocarbon dating held in Europe took place in Cambridge during the week July 25–30. Dr. H. Godwin, head of the Cambridge dating laboratory at the University Sub-department of Quaternary Research, Botany School, was the host and inspiring organizer of a most successful and instructive symposium. He assembled a small group of scientists representing almost all the dating stations in Europe, plus a few physicists who are in the process of setting up dating equipment. Thanks to a generous grant from the Wenner-Gren Foundation, New York, it had also been possible to invite a few of the leading Americans in this field. Thus, the conference was a first step towards the goal set in Copenhagen a year ago, where the establishment of closer personal contact with American colleagues was considered essential for future discussions—in Europe—of the implications of radiocarbon dating.

The Cambridge conference was devoted almost exclusively to the discussion of new methods, which have undergone rapid development in the past two years. The classical Libby method of 'counting' solid carbon in the screen-wall counter is being abandoned, mainly because the widespread contamination of the atmosphere with radioactive dust—although probably too low to be of significance as a health hazard—represents a serious menace to accurate low-level assay. This is particularly true in the case of 'black carbon' samples with their extremely large surfaces and high adsorption capacities.

In the United States and in Europe, a number of new approaches to the measurement of natural radiocarbon have been made simultaneously; for example, gas counting of carbon dioxide, acetylene and methane, and scintillation counting in which the sample to be dated is incorporated into the scintillator. Each of the methods mentioned was discussed in detail at the Cambridge conference, and a comparison of the merits of various techniques was attempted, especially as regards the ease and speed of operation, the accuracy achieved within a given counting time, the relative sample sizes, etc.

Just as at last year's conference in Copenhagen, the question of errors of radiocarbon ages was the subject of lively discussions. In the solid carbon method, the statistical error of the net count represents the largest contribution to the error of the final result. As this error is being suppressed by improving the ratio $S^2/B$ (sample over background), other factors such as isotopic fractionation during processing of the samples, variations in the natural isotopic constitution of the unknown and the reference sample, and the uncertainty in the half-life of radiocarbon, etc., begin to play an appreciable part in estimating the accuracy of radiocarbon measurements. Different errors have been combined in a variety of ways, and very few publications contain a concise statement as to how the errors listed have been computed.

A solution of this problem acceptable to all participants could not be found during the Cambridge meeting; but it was agreed that the manner in which the error is calculated should be stated explicitly in future publications.

Moreover, the standardization of the form of publication of dating results was discussed. All investigators present agreed that dating results should be collected at regular intervals for publication in either *Nature* or *Science*. They should preferably appear in the form of date lists similar to those issued by Libby, containing only a brief description of the sample, its current laboratory number and the station's identification prefix letter (cf. below). Obviously, publication of date lists will not replace presentation of the same results in their proper context in any other scientific journal; however, it will make the dating results of various stations more readily accessible to those interested in any one of the widely differing fields of application of the radiocarbon dating method. Also, the results of inter-laboratory cross-checking and standardization, as well as of mass-spectrometric monitoring, are of interest to many workers in this and related fields, and all data should be made available to the widest possible circle of readers. A list of the dating stations in operation or close to completion, and the identification prefix letters used or accepted for use by these stations, is given in Table 1, and additional information will be appreciated.

Table 1. DATING LABORATORIES

In this connexion it may be mentioned that an informal exchange of scientific information between European dating laboratories has been in existence for almost two years, and an effort is being made to maintain and widen such contacts among scientists actually engaged in radiocarbon dating.

The meeting in Cambridge has given ample evidence of the great need for and interest in small conferences, where experience and progress within this rapidly developing field are discussed informally. The method of radiocarbon dating is still new, and further technical improvements are likely to come. On the other hand, its wide range of applicability has not yet been fully understood and appreciated. Therefore, joint meetings of physicists and chemists with archæologists, geologists and other users of dating results are bound to be mutually instructive and stimulating, provided the groups can be kept small and scientists with as remotely related interests as atomic physics and history of human cultures can discuss the essentials, each making an effort to understand the others' problems. HILDE LEVI

# ANIMAL PRODUCTION FROM GRASS

THE theme of "Animal Production from Grass" proved a most successful choice for the fifth 'study meeting' of the European Association of Animal Production, which was held at Reading during July. Representatives of seventeen countries were present, and all stayed in two of the University's halls of residence; this contributed on the social side towards the success of the meeting.

As a preliminary to the meeting, most of the visiting European delegates took part in a tour beginning with a visit to the Royal Show at Nottingham, where the Council of the Royal Agricultural Society extended its hospitality to the visitors. Particular interest was shown in the display of British breeds of livestock. Afterwards, visits were made to the research farm at Thurgarton and the Veterinary Research Unit of Messrs. Boots, and to Mr. Maurice Passmore's farm at Wormleighton.

At Reading, the theme for discussion was introduced by two main papers, each being followed by shorter reports on current research in the various countries. On the first day, Prof. M. M. Cooper, of King's College, Newcastle upon Tyne, delivered the chief contribution on "Animal Management for Intensive Production from Grass". This comprehensive review of the present position in farm practice and in the experimental field was both stimulating and provocative and delivered with characteristic vigour. Prof. Cooper directed attention to the discrepancies that exist between the recorded output from grassland under experimental conditions and that obtained on most farms, even those under more progressive management. For this the farmer must not be judged harshly. Many lack the capital to ensure better utilization, while generally there is a lack of the technical knowledge of how to produce grass with "the composition of a watered concentrate for eight or nine months of the year in sufficient quantities to meet the nutritive demands of high-producing cows"; and there is no simple recipe the adviser can give the farmer to enable him to do so.

In Britain the well-distributed rainfall and the fact that eighty acres is the size of the typical farm have made the higher efficiency of the dairy cow a dominating factor, and she is the pivot of a system of mixed farming. The meat-producing sheep is important on large arable farms and on the large, preponderantly grass farms of the north, where cattle may be merely mowing machines to keep the grass in good condition for maximum mutton production. One of the current problems is the extent to which sheep can be integrated into dairy farming. Some sheep on a typical large dairy farm are a necessity for proper pasture management; and in establishing a directly re-seeded pasture, they are invaluable in effecting consolidation and controlling weeds in the early stages. Used sensibly, they can augment the quality of grazing for the dairy herd; but in such circumstances, they are essentially scavengers, which is also their proper role on a large arable farm with limited grass.

Prof. Cooper also discussed systems of grazing, pointing out that trials in New Zealand gave better live-weight gains, carcass weights and lamb grading from rotational grazing where the stocking-rates were high than from non-rotational grazing, but that at low rates of stocking the reverse was true. On conservation of grass we have much to learn from Continental countries. Though we should aim at maximum use *in situ*, with the reduced conservation losses, lower handling costs and better return of animal excrement to maintain fertility, conservation is also essential and is a means as well as an end in intensive pasture management.

Finally, Prof. Cooper appealed for a better assessment of nutrient off-take from pasture. It is absurd to credit full value to concentrates and other foods of known analysis, leaving grass and grass products to carry all the errors of estimate. Such a system, now current, discounts the value of grassland under a system where both grass and concentrates are fed, and makes intensive grassland management appear less efficient than it actually is.

The first of the subsidiary papers was by Dr. W. Holmes and D. S. MacLusky, of the Hannah Dairy Research Institute. They reviewed the effects of pasture management methods on the production and feed consumption of dairy cows in trials on the Institute's farm. Production per acre was in many cases the final objective, and for this purpose maximum herbage consumption per cow might not be the best policy, as it might be obtained at the expense of efficient food conversion. Possibly slightly more mature herbage than the ideal may sustain more cattle per acre with only negligible reduction in yields per cow. Provided weather and good management ensure a constant supply of good grass, the strip-grazing method without cutting the grass or providing supplementary feed appear to give the most satisfactory results.

In a report of "A Comparison of Systems of Sheep Grazing Management" carried out at Wye College, Kent, H. Cornforth dealt with two sheep-grazing trials. Where nitrogenous fertilizers were used, rotational grazing gave the best utilization. Three days appeared to be the maximum that fattening sheep should remain on each plot. Gang-mowing had an advantage under continuous grazing where no nitrogenous fertilizer was used, but not where nitrogen was applied. Rotational grazing of a sward treated with nitrogen gave almost 700 lb. live-weight gain per acre, which is 27 per cent better than from a continuous grazing treatment on the same light chalk soil.

Other papers in this section were from Yugoslavia, Germany, The Netherlands, Austria, Portugal and Switzerland. That from P. B. De Boer, a Netherlands farmer, outlined his methods of intensive grassland farming, designed to try to eliminate the estimated

3 per cent loss of grown herbage in the process of grazing and conservation. This is done by strip grazing for limited periods and housing the cows at night. Each field is cut or grazed five or six times per season, nitrogenous fertilizer being applied following each cut or grazing period. By alternating cutting and grazing, palatability is improved. Dung is only applied to fields the crops of which are to be cut for silage the following season. The yield of cows shows that grass grown in September or October is not so productive of milk as that grown earlier in the summer. Starchy foods are used to balance the grass and give better utilization.

The second session of the meeting was devoted to the "Agronomic and Physiological Considerations governing Grassland Utilization". For this subject the principal paper was in two parts, the first on the physiological aspects being given by A. M. Frens, of The Netherlands State Agricultural Experiment Station at Hoorn, while the second, on the economic principles of grassland farming, was given by H. Dijkstra, of The Netherlands Agricultural Economics Research Institute.

Mr. Frens, in a clear and persuasive paper, pointed out the difficulties with which cattle on intensively managed pasture have to contend in dealing with the physical structure and high moisture content of young tender grass on which they are expected to live for long periods. Where the feed is low in fibrous and stemmy components, it tends to pack too closely in the rumen, and optimal microbial activity does not develop. This may lead in extreme cases to a deficiency of those nutrients of microbial origin which are essential to the animal's well-being. Not only so, but also the large quantities of water that have to be dealt with by animals living on luscious young grass strain their resorptive capacity, and water resorption from the intestines may be less effective than it physiologically should be. This results in soft fæces, in which an excess of minerals is excreted. Cattle which are scouring, moreover, tend to have a greater sodium and copper requirement, and the grass may contain insufficient to meet the extra demand caused by the increased loss by excretion. Supplementary food to give additional fibre to cattle on highly stimulated pastures can be an advantage, even if the grass contains all the nutrients needed for the animal's level of production. It should be chosen carefully, so that it does not prevent a high intake of grass, and the inclusion of extra sodium, copper and perhaps magnesium may be worth while.

Mr. Dijkstra's paper was the only one dealing with economic aspects. He laid down three conditions that must be fulfilled for the most economical production: (*a*) grass and grass products must be adapted, in the most economical way and along with any purchased feeding-stuffs, to the feeding requirements of the farm livestock; (*b*) the farm equipment, seeds, fertilizers and labour used must be so applied that no greater net output could be obtained by utilizing them in any other line of production; and (*c*) the primary products of the enterprise (grassland products) must be converted as efficiently as possible into the secondary products (milk, meat, etc.). These three conditions are not independent of each other, but have a mutual influence.

There were twelve subsidiary papers in this session, of which two were contributed from the United Kingdom. W. F. Raymond, of the Grassland Research Station, reviewed the problems involved in the "Estimation of Herbage consumed by Grazing Stock". At the Grassland Research Station, as in New Zealand, the fæcal index method is being developed. It is felt that this method is likely to give greater accuracy than others being tried in America; and that from it an estimate of the grazing intake can be made and a measure of the herbage quality obtained. While the technique is simple to operate, it is dependent on adequate sampling, and to this greater attention has still to be given. J. L. Corbett, of the Rowett Research Institute, dealt with "Some Aspects of the Nutrition of Grazing Dairy Cows" and gave details of trials in which the effects of supplementary foods on herbage intake were studied.

Other contributions were from France, Portugal, Switzerland, Belgium, Germany, The Netherlands, Finland and Italy. Dr. L. Seekles, of The Netherlands, dealt with grass or lactation tetany, to which he prefers to give the name 'nutrition tetany'. He criticized the suggestion frequently made that intensively fertilized pasture is a prime cause, since it may occur both on lush pastures and in stall-fed cattle. In addition to the visible symptoms of tetany, there is also gastro-intestinal disfunction. It is possible that certain poisons of intestinal origin interfere with the magnesium-regulating centre in the brain, causing a shift of magnesium from the blood to the tissues. This may be initiated by abnormal functioning of the digestive tract due to its overburdening with excessive food, whether it be lush pasture or other foods. More than one contributor directed attention to the importance of developing the correct bacterial flora for the best digestive utilization of silage. Invariably, animals to which silage is introduced make little or no progress for some time, though later they may recover the lost ground. This appears to be due to the time taken for the correct bacteria for digestion of silage to develop. Further study of this aspect of digestion and of the best utilization of various forages is needed.

A characteristic of both sessions was the vigorous discussion, which was ably directed by the president, Prof. A. M. Leroy. The meeting concluded with the adoption of a resolution calling for intensified research on international lines on the problems of producing a high yield of good-quality grass and of its utilization. There is still, except in some circumstances, a failure to use the full potentiality of the grass crop.

A. R. WANNOP

# INSTITUTE OF MEDICAL LABORATORY TECHNOLOGY

## SEVENTH TRIENNIAL CONFERENCE

THE seventh triennial conference of the Institute of Medical Laboratory Technology was held in the University of Nottingham during August 29–September 2. In opening the conference, Dr. G. E. Godber, joint deputy chief medical officer to the Ministry of Health, spoke on the development of the pathology services in Great Britain. He began, appropriately, by showing the build-up of laboratory services in the North Midland Region since the beginning of the Second World War, during which the Emergency Pathology Service became the forerunner of the existing network. In spite of war-time improvements, the pathological services over the whole country were far short of requirements when the National Health Service took over in 1948.

Between then and 1954 the amount of pathological work has doubled; almost two thousand technicians and about the same number of student technicians were employed last year in National Health Service laboratories. This increase of laboratory work should be looked upon as part of a process established before the Health Service or even before the War. We have moved from the conception of a hospital which was primarily to provide beds in which patients recovered with varying degrees of assistance from their attendants, to one in which the hospital is a diagnostic and treatment centre, where most patients are out-patients, their needs being met without admission. Admission to the ward is now regarded as a stage in the patient's life and illness which should in his own interests be cut as short as is compatible with speedy and effective cure. Briefly, the hospital is a special kind of service which stands behind, and supports, the great bulk of curative work that is done in other places—surgeries, clinics and the patients' own homes.

Naturally, the bulk of the most complex and highly scientific work is done for patients attending consultative out-patient departments or admitted to the wards. This should not hide the importance of the laboratory's share in diagnosis and treatment in other places, and it is necessary that this side of its work should be expanded. The work of general practitioners is of great importance because so much of it can lead to earlier diagnosis, prevention of serious illness, and the reduction of the load on other departments of the hospital. There is ample evidence that the availability of the pathology laboratory to the general practitioner does not swamp the laboratory with work at the expense of the requirements of the hospital itself: it may even have the opposite effect. That every practitioner should be able to refer his cases direct to the laboratory is a prime necessity.

Speaking of the capital development plan for hospitals, Dr. Godber said that it is commonly believed that a new hospital must necessarily cost more to run than an old one, and it may be that a new one will cost more per bed per year; but if the new hospital makes it possible to treat three patients in the number of bed-days formerly required for two, then there is a margin for increasing cost per patient-day and still reducing the cost per patient treated. A modern pathological service can do much to enhance this process, and particular care is needed in hospital planning to ensure that such departments as pathology and radiology are on a sufficient scale to meet all requirements efficiently and at the same time with economy in man-power.

The laboratory, continued Dr. Godber, is part of the hospital and should not be divorced from it; the clinician relies upon laboratory workers for accurate and expert information which gives him the assurance that enables him to control the complicated armamentarium of treatments. Diagnosis is, after all, rarely a simple process of exact definition and needs a balance of evidence from a variety of sources. Likewise, modern treatments often need the most exacting control, and for these reasons there needs to be close contact between the laboratory and the clinician. Along with the use of more complicated and more accurate apparatus, there has been an increasing devolution of responsibility to the technical staffs of medical laboratories. The Institute of Medical Laboratory Technology has played a great part in facilitating the changes which have taken place in the past few years by its promotion of education and its qualifying examinations and by maintaining and achieving a status for the medical laboratory technician which is now recognized in Britain throughout the national hospital service and all other laboratories.

There were five sessions of scientific lectures at the conference, about two-thirds of which were given by Institute members and the remainder by guest speakers. Dr. M. Lumb spoke on the influence of antibiotics on modern clinical bacteriology; the influence of these substances in the treatment and bacteriology of tuberculosis occupied part of the talk given by Prof. Robert Cruickshank, president of the Institute. Some of the most interesting of the recent problems in this disease have been raised by the type of lesion in which the tubercle bacillus can be demonstrated microscopically but not culturally. Prof. Cruickshank ended his observations with a very necessary warning to laboratory workers. Many laboratories are now handling tuberculous material, and the need for antibiotic control has resulted in a great increase of living culture work. The incidence of the disease in laboratory workers is disturbing, and every possible care should be taken to guard against laboratory infection.

Prof. E. J. W. Barrington, of the Department of Zoology in the University of Nottingham, was able to show a common meeting-ground for those who work in pathology departments and those who work in other specialties, when he spoke of the place of histology in endocrinological research. Certain of the new cytochemical methods, he said, are of equal value in the earthworm and in man. Mr. F. A. Ibbott gave a provocative paper on the error induced in volumetric glassware by drying and sterilization with heat; his own experiments, some of them drastic, have shown that no significant changes were produced by dry heat in certain of his own standard apparatus. Dr. J. C. White, of the Postgraduate Medical School of London, gathered together recent advances in our knowledge of the human hæmoglobins, while Dr. N. P. Burman dealt with methods of detecting and counting antagonistic micro-organisms in soil and described some of his own methods for simplifying a tedious and time-consuming process.

Prof. K. E. Cooper, professor of bacteriology in the University of Bristol, took modern trends in microscopy as his subject and illustrated the principles of phase-contrast, electron and interference microscopy. Speaking of ordinary microscopy, Prof. Cooper deplored the tendency of some workers to set up a very good microscope with a poor illuminating system, so not making full use of their instrument. Mr. J. S. Simpson showed methods employed in the microbiological assay of antibiotics, vitamins and amino-acids, and was able to demonstrate how the use of large sandwiches of agar between glass plates saves the use of considerable quantities of Petri dishes. Dr. G. R. Osborn, director of pathology, Derbyshire Royal Infirmary, gave many examples of the use of modern cytological techniques in the early diagnosis of cancer, and he was followed by Miss M. E. Attwood, who has applied such techniques to the problem of diagnosing uterine carcinoma in particular.

Among other papers were those of Miss V. A. L. Brews, who dealt with electrophoretic patterns of blood sera and the flocculation tests, while Miss E. L. Bown gave a résumé of semi-micro methods used in pædiatric biochemistry. Dr. H. M. Rice, director of pathology, General Hospital, Nottingham, made observations on the sensitivity of the hæmolytic system in complement fixation tests and showed the greater reliability of modern modifications in the tests, for example, for syphilis. Mr. I. Dunsford, of the Sheffield Blood Transfusion Service, was able to draw on an extensive practical experience in discussing the difficulties encountered when selecting suitable blood for transfusion purposes. His main point was that no one test should be relied upon when cross-matching blood but that saline and albumin techniques should always be employed, with the addition of the Coombs test in cases where there was a risk of the patient having been immunized by previous transfusions or pregnancies.

In addition to these and other papers, numerous demonstrations were on view all the week. For the first time at an Institute conference a large number of foreign laboratory workers were present, and an evening was spent on discussion of matters of common interest. Another innovation was a demonstration for the public who, generally speaking, are not very knowledgeable about what takes place in the hospital laboratory. This demonstration, the result of much co-operation between local pathologists, technicians and many others, was open for only three hours on each of two successive evenings; but the success of the experiment may be judged by the fact that during this short time more than a thousand people visited it.

# PRESERVATION OF FOOD BY IONIZING RADIATIONS

THE traditional methods available for the preservation of food are several and varied in their nature. The almost prehistoric method of drying involving the use of solar radiations—unrecognized as such—was the subject of much research some years ago, and this work was very useful to Great Britain during the Second World War when there was a great shortage of shipping space. Some of the chemical preservatives, studied by the 1924 Departmental Committee of the Ministry of Health, often 'blunderbuss' in function, are virtually unused outside the British Isles where those of more recent introduction have been found acceptable both by the industry and the authorities. The availability of antibiotics—some very specific in their action—has created new problems for those who advise our legislators on the desirability of permitting additions to the schedule of preservatives, for such they are. In the realm of food science, experimentation and development, although more sedate in their progress compared with some of the other branches of science, often outstrip the ability of the manufacturers to take advantage of them.

The initial discovery by Röntgen in 1895 that X-rays can damage and destroy living cells has in more recent years been extended over the broader field of ionizing radiations in general. The situation to date, as recorded in various journals mainly of American origin, is that radiations derived from electrical generators, radioactive elements and nuclear reactions are available which exert a lethal effect upon micro-organisms and insects. Parallel with these observations have been reports of reactions initiated by the exposure of food components to such radiations—breakdown of amino-acids, fats, vitamins and so on. The food technologist faced with a new series of units representing the dosage of the product under treatment has often been in difficulty in grasping the significance of the evidence given in these reports, and the very long list of journals in which such reports are sometimes hidden only adds to his confusion. With considerable foresight, the Food Investigation Organization of the Department of Scientific and Industrial Research, as befits its name, has come to the aid of food technologists in providing, through the efforts of Dr. R. S. Hannan, a wealth of information and, let us not delude ourselves, of instruction in its Special Report No. 61 on "Scientific and Technological Problems involved in using Ionizing Radiations for the Preservation of Food"*. The bibliography of some four hundred odd references in this publication will satisfy every collector of reprints and is alone worth every penny of the modest price.

In his survey, Dr. Hannan deals with the ionizing radiations, their generation, their properties and the technical problems associated with their use. Having described the positive advantages of the use of this modern weapon, he very wisely presents for the reader's consideration the various gaps in our knowledge which must be filled before we are able to contemplate using it. The most suitable type of radiation and its optimum dose, the possibility of reactions initiated by such dosage involving the production of undesirable and maybe toxic substances or the destruction of some essential constituent—all these will need to be studied *in extenso* and by teams of workers. We are grateful for the information and for the guidance as to future research, and we look forward to the results of the further researches of Dr. Hannan and his colleagues.

# PHYSICS OF THE IONOSPHERE

THE rapid advances being made in many fields of scientific research leads to a vast amount of published literature in which it is not easy for the student and research worker to discover the real milestones of progress. As a means of partly mitigating this difficulty, there is now an established practice of organizing a conference or symposium at which a particular subject or field of investigation is reviewed and discussed, mainly by those working in the subject. Such a conference forms a suitable focus and also acts as a stimulant to those who otherwise may be rather dilatory in describing their own contributions or putting forward well-founded views on the work of others. The results of such a conference are made of immensely greater value when all the papers which were read and discussed are collected together and published in some recognized standard form.

The conference on "The Physics of the Ionosphere", held under the auspices of the Physical Society at the Cavendish Laboratory, Cambridge, in September 1954 (*Nature*, 174, 866; 1954), meets all these requirements with the publication of the report which is now available*. The report comprises fifty individual papers from authors in Australia, Canada, France, Germany, Great Britain, India, Japan and the United States. It is divided into four parts, each of which is introduced by a survey paper, with a most useful selected list of references.

---

* Physical Society. Report of the Physical Society Conference on the Physics of the Ionosphere, held at the Cavendish Laboratory, Cambridge, September 1954. Pp. iv+406. (London: Physical Society, 1955.) 40*s.*

In the first paper in Part 1, entitled "The Lowest Ionosphere", Prof. A. H. Waynick summarizes the recent radio data which may be used as a guide to the possible physical characteristics of the lowest regions of the ionosphere. These characteristics are primarily concerned with the absorption of short waves and their partial reflexion from the lower ionosphere, and the height of reflexion of very long waves. It is pointed out that great advances in our knowledge of the lower ionosphere is likely to occur in the near future. Recent rocket measurements of X-ray intensities in the neighbourhood of 50 A. suggest that this radiation may well be the primary source of energy associated with the formation of the *E* region. In addition, there now appears to be evidence for postulating the existence of a portion of the *E* region due to meteoric ionization. The remaining nine papers in Part 1 describe work conducted in this field in Great Britain, North America, Germany and India.

The second part of the report, "Irregularities and Movements in the Ionosphere", opens with a survey of existing knowledge by Mr. J. A. Ratcliffe. At all heights in the ionosphere there are randomly distributed irregularities in the electron density. Information on these irregularities—their size, shape and movement—is obtained from a study of the fading characteristics of waves reflected from, or transmitted through, the appropriate part of the ionosphere. The study of the fading observed at spaced receiving stations has contributed greatly to our knowledge of the movement of these irregularities. During recent years, measurements of the propagation of very-high-frequency waves by scattering from the *D* and *E* regions and from aurora are finding increased application. Observations on the scintillation of radio stars also enable drift movements in the *F* region to be investigated. The sixteen papers collected with the survey in this part of the report form a very complete and up-to-date appreciation of the state of experimental and theoretical knowledge of this subject.

"A Survey of Present Knowledge of the *F*2 Region", by Dr. D. F. Martyn, is the first paper in Part 3, and describes the salient features of the *F*2 region, including the production of its ionization, the recombination coefficients, winds and travelling disturbances, and the storms and anomalies associated with this region. While the other eight papers in this section summarize the present state of knowledge, including theoretical speculation, of conditions in the *F*2 layer, a brief reference is made, in an addendum to the survey, to the wealth of information which was obtained by a rocket ascent in May 1954 to a height of 219 km. A mass-spectrograph was used and data obtained on the composition and pressure in the upper atmosphere. While the results await confirmation, this is undoubtedly an indication of the success of a new technique for exploring the ionosphere.

The fourth and final part of the report deals with "The Mathematics of Wave Propagation through the Ionosphere", and is surveyed by Mr. K. G. Budden. With thirteen other papers, this section describes the mathematical technique used in the study of the properties of the ionosphere, and particularly the variation of ionization density with height, the resulting refractive index and the paths of radio waves in traversing the various ionospheric layers. This section is complementary to the previous three and makes the whole report a comprehensive work of reference which will be of the greatest value to students and research workers for many years to come. The publication of the report must be a very gratifying conclusion to the efforts of Mr. Ratcliffe and his colleagues who were responsible for the conception and organization of this conference.

---

# AUXIN AND PROTOPLASMIC STREAMING

It has now been known for some considerable time that indoleacetic acid and other growth-regulating substances increase the rate of protoplasmic streaming, but no generally accepted explanation of the phenomenon has yet been advanced. J. M. Kelso and J. S. Turner (*Austral. J. Biol. Sci.*, **8**, 1, 19; 1955) have now reported on the action of various growth-regulating substances on streaming in single cells of the staminal hairs of *Tradescantia virginiana*.

As the rate of protoplasmic streaming in these cells is not affected by change of oxygen concentration in a hanging drop enclosing the hairs over the range 1·5–100 per cent of oxygen in the surrounding gas phase, experiments can be carried out without continuous renewal of the water drop. It was observed that, over the physiological range of concentrations, indoleacetic acid, indolebutyric acid, naphthaleneacetic acid and 2,4-dichlorophenoxyacetic acid, all modify the rate of protoplasmic streaming. These substances, added alone, bring about changes in the rate of streaming within 10 min.; maximum effects are reached in 30 min., and the rates return to the normal in 60–70 min. (exceptions to this rule are noted for naphthaleneacetic acid (high concentrations) and 2,4-dichlorophenoxyacetic acid (low concentrations)). Low concentrations of the auxins stimulate the streaming, high concentrations depress the rate, and intermediate concentrations are without effect.

Auxins thus affect streaming much as they do the growth of stems, the optimal concentrations for stimulation being similar for both processes. The 'total effect' for each growth substance may be estimated as the total extra or diminished distance travelled by a protoplasmic particle in the presence of the applied substance. The maximum positive total effect is given at 1 mgm./l. (1 p.p.m.) for indoleacetic acid and indolebutyric acid, and at 5 mgm./l. for naphthaleneacetic acid. There is a marked *p*H effect for the reaction of streaming to indoleacetic acid, increase in *p*H rendering the applied solution much less effective over the whole range of concentration. The temporary effects of indoleacetic acid on streaming, both stimulation and inhibition, are stabilized near their maximal values, if fructose or malic acid is added with the auxin. These results largely confirm those obtained by Thimann and Sweeney for the *Avena* coleoptile, except that the concentration for indoleacetic acid giving maximal total effect for *Avena* is as low as 0·01 mgm./l. Moreover, for *Avena*, malic acid not only stabilizes the auxin effect but also alters the threshold of response.

# COSMIC RADIATION EFFECTS IN METEORITES

By DR. P. REASBECK
Physics Laboratory, University of Birmingham
AND
DR. K. I. MAYNE
Clarendon Laboratory, University of Oxford

RECENT studies of meteorites[1] showed that they contain an appreciable amount of helium-3 produced by cosmic rays. The interactions of high-energy cosmic-ray particles with the meteoritic matter will produce effects which are propagated to great depths by secondary particles as well as primaries. Nuclei of a wide range of mass numbers less than that of the original should occur in varying proportions, either as evaporation products or as residual nuclei.

We have investigated the production of nuclei of mass 3 and 4 [1] (evaporation products); we now report some measurements on the neon isotopes (residual nuclei) in iron meteorites. The data for helium and neon from four irons are given in Table 1.

Because the amount of neon is two orders of magnitude smaller than the amount of helium, only in the case of Thunda was enough neon available for mass-spectrometric analysis; the precision of this analysis is better than 5 per cent. The measurement is complicated by the presence of instrumental background peaks at mass 20 and 22, due to $H_2{}^{18}O^+$ and $CO_2{}^{++}$ respectively. The former was considerably reduced by replacing oxygen-18 by oxygen-16, the latter by using an (electron) ionizing voltage of 35 V. The method of helium and neon separation has been described elsewhere[2], but special care was taken to remove adsorbed atmospheric neon from the containing vessel before commencing dissolution of the meteorite sample. The amount of atmospheric neon contamination was less than $10^{-9}$ c.c., which represented less than 1 per cent of the meteoric neon finally measured.

It would appear from the isotopic analysis of the extracted neon that all its isotopes arise from the original iron nuclei after the direct ejection and evaporation of nucleons are completed. Such events as these are the 'stars' recorded in photographic emulsions exposed at high altitudes; and we have used the statistical data obtained from photographic plates to estimate the rate of production of neon by cosmic radiation. The degradation of the iron nucleus ($Z = 26$) to neon ($Z = 10$) involves the emission of 16 units of charge from the parent; but since some of the emitted particles will carry a multiple charge (helium nuclei), it seems, taking the He/$p$ ratio of about 0·3 derived by evaporation theory[3], that the events with which we are concerned will appear on the photographic plate as stars of about thirteen prongs. Taking the rate of star production by cosmic rays in photographic emulsions as about 2,500 stars/c.c./day at the top of the atmosphere[4], this is increased by a factor of 2 to give the rate of production in iron, and by a further factor of 2 to obtain the rate away from the earth's shielding effect. From the data given by Lord[4], it would seem that about 2 per cent of the total stars produced are thirteen-pronged events. Even if any cut-off of low-energy particles due to the earth's magnetic field does exist, one would not expect the figure of 2 per cent of the total stars giving neon to be very much altered in space, since only high-energy particles will give rise to thirteen-pronged events. Thus we calculate a rate of production of neon of about twenty-five neon atoms/gm. iron/day. In addition, one would expect the isotopes sodium-20, 21 and 22, and fluorine-20 and 21 to be produced in such quantities that, in decaying into a neon isotope, and more than replacing the loss due to neon-19 and 23, they will approximately double the yield of neon, making a total of fifty neon atoms/gm. iron/day.

We have already suggested[5] the possibility that the cataclysmic break-up of a parent planet formed the meteorite fragments about $2 \times 10^8$ years ago. On the basis of the above data, one would expect the neon produced in an unshielded fragment to be about $1·35 \times 10^{-7}$ c.c./gm. iron, and the isotopic composition and large yield of the helium extracted from our sample of Thunda would indicate that this piece was relatively unshielded from the cosmic radiation. Since it seems that the helium-3 and neon in a meteorite are all produced by cosmic radiation, one would expect approximately the same ratio of neon to helium-3 in any unshielded sample. This ratio for the four samples concerned is given in Table 1 and the values obtained prove to be closely similar. The calculations of Le Couteur[3] suggest that about 37 per cent of the total yield of particles from 'evaporation stars' will be in the form of helium-4, helium-3, or tritium, all of which will be recorded as helium after a suitable lapse of time. Taking the average number of prongs per star as ten at the average cosmic-ray energy concerned, and using the measured ratio ($^3$He + $^3$H)/$^4$He of 30 per cent, we can deduce a figure of about a hundred atoms of ($^3$He + $^3$H) per hundred stars. (The tritium we eventually measure as helium-3.) Using again the figure mentioned above of two to four neon atoms per hundred stars, we would expect the neon/helium-3 ratio to be between 2 and 4 per cent, comparing favourably with the measured value.

Table 1

| Meteorite | Helium ($10^{-6}$ c.c./gm.) | Neon ($10^{-8}$ c.c./gm.) | Ratio He/Ne | $^3$He/$^4$He (per cent) | Ne/$^3$He (per cent) | Per cent neon-20 | 21 | 22 |
|---|---|---|---|---|---|---|---|---|
| Thunda | 29·05 | 18·9 | 154 | 30·7 | 2·71 | 43 | 36 | 21 |
| Toluca (Durham) | 18·6 | 11·4 | 164 | 29·7 | 2·60 | | | |
| Carbo (3 cm.) | 20·94 | 12·3 | 171 | 28·6 | 2·63 | | | |
| Carbo (0·5 cm.) | 22·36 | 13·2 | 169 | 28·4 | 2·69 | | | |

We have also compared our results with those obtained from recent laboratory experiments on high-energy reactions induced by protons in copper[6]. In Table 2 are listed the estimated production cross-sections (from copper) of the

Table 2

| Isotope | Estimated cross-sections (m.barns) |
|---|---|
| Sodium-20 | 0·6 |
| Sodium-21 | 1·0 |
| Sodium-22 | 2·0 |
| Neon-20 | 4·0 |
| Neon-21 | 3·0 |
| Neon-22 | 2·5 |
| Fluorine-20 | 2·5 |
| Fluorine-21 | 0·5 |

nuclear species which end in neon isotopes. The variation of cross-section with $Z$ for a given element was estimated from the average shape of the curve for all neighbouring elements, as discussed by Batzel *et al.*[6].

Taking these values, the isotopic composition of the neon produced should be: neon-20, 44 per cent; neon-21 and neon-22, 28 per cent. Our measured isotopic ratios given in Table 1 are in reasonable agreement with these estimates, considering the uncertainties in the cross-sections, and in the energy spectrum of the cosmic rays.

With the data of Table 2 we may make an independent calculation of the rate of production of neon. Because we are considering reactions in iron (8 mass units from copper), we increase the cross-section values by 20 per cent; that is, we take 20 m.barns as the total cross-section for neon production. For a cosmic-ray intensity[4] of 0·3 particle/cm.$^2$/sec./sterad., $2 \cdot 6 \times 10^4$ atoms of neon are produced per gm. of iron per year; or in $2 \times 10^8$ years, about $2 \times 10^{-7}$ c.c. neon/gm. iron, a value once again close to the measured neon content.

It seems that the cosmic radiation to which the fragments have been subjected since the parent was broken up has produced measurable quantities of many nuclides lighter than iron, the study of which should lead to a better understanding of the radiation and the high-energy processes involved. We are continuing our investigations, particularly for samples of greater depth, and extending them to cosmogenic argon.

We would expect that the events which produce argon ($Z = 18$) from iron ($Z = 26$) would appear as six- or seven-pronged stars, and again using the data of Lord[4], we find that argon should be produced about four to five times as abundantly as neon, suggesting a cosmogenic argon content for unshielded meteoritic iron samples of about $6 \times 10^{-7}$ c.c./gm. In addition, it is to be expected that the isotopic composition of cosmogenic argon would differ markedly from that of atmospheric argon, with argon-36 and argon-38 much more predominant in the former source than in the latter.

If this proves to be correct, it should be possible to predict the amount of many other cosmogenic isotopes in meteorites, and to decide which of these will lend themselves most readily to experimental determination.

We are grateful to Dr. W. O. Lock and Dr. S. J. Goldsack, of the University of Birmingham, who helped to interpret the photographic emulsion data; and to Dr. J. L. Symonds, of the University of Birmingham, who provided the data derived from high-energy proton-induced reactions. We would also thank Prof. F. A. Paneth for his interest in the work and for providing samples of meteorites.

# MECHANISM OF SOME REDUCTION PROCESSES ILLUSTRATED ON A COENZYME I MODEL SUBSTANCE

By Dr. GABRIEL STEIN and GAD STIASSNY
Department of Physical Chemistry, Hebrew University, Jerusalem

THE enzymatic reduction of coenzyme I (diphosphopyridine nucleotide) has been the subject of many investigations and discussions recently[1]. The product obtained by reducing coenzyme I with hydrosulphite can be reoxidized enzymatically, as of course can the reduced coenzyme I formed by enzymatic reduction. It was recently shown that the reduction product obtained[2] from coenzyme I when reactive intermediates produced from, for example, ethanol in irradiated aqueous solutions were used as the reducing agents was not identical with the product of hydrosulphite reduction[3]. This reduction product was enzymatically totally inactive. Borohydride reduction yields a product which could be reoxidized enzymatically to the extent of about 50 per cent[4].

The chemistry of these processes has been investigated on N′-alkyl nicotinamide derivatives, which represent the active group of coenzyme I[5]. Karrer[6] isolated the hydrosulphite reduction products of several such derivatives and compared them with reduced coenzyme I, which they resembled closely. Such a substance was used in electrolytic and polarographic investigations of coenzyme I model systems[7,8].

Using such a model substance, it was also shown[3] that as, in the case of coenzyme I, when reactive intermediates formed in irradiated aqueous solutions were used as the reducing agent, a reduction product is obtained which is closely related to, but not identical with, the product of hydrosulphite reduction.

The work of Colowick[9] and Swallow (results in the press) indicate that the enzymatic and hydrosulphite reductions of coenzyme I proceed not through a free-radical intermediate, as sometimes assumed, but through an ionic addition mechanism. On the other hand, the mode of action in the irradiated system was assumed[3,10,11] to be due to the intermediate formation of free radicals. The ionizing radiation would in the main act on the bulk of the aqueous solvent, producing radicals according to[12]:

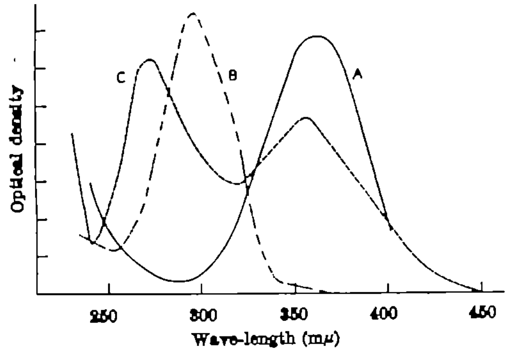

Fig. 1. Absorption spectra of: (*A*) product of hydrosulphite reduction; (*B*) product of acid treatment; (*C*) product of reduction in irradiated solution. Optical density in arbitrary units

$$HOH \rightarrow H + OH \qquad (1)$$

OH radicals attack the ethanol according to:

$$RH_2 + OH \rightarrow \dot{R}H + HOH \qquad (2)$$

The organic free radicals, $\dot{R}H$, thus formed are apparently efficient reducing agents of coenzyme I, themselves being oxidized to acetaldehyde.

Thus it appeared possible that, in the present case, closely related but not identical products are produced through different mechanisms of reduction. Accordingly, using nicotinamide-N′-propyl iodide as the model substance, we have examined some modes of reduction.

Using hydrosulphite, a pure crystalline reduction product could be isolated, melting point 86° C. Elementary analysis and oxidative titration showed it to be a dihydro-isomer. The absorption spectrum of the product in carbonate alkaline solution is shown in Fig. 1, curve *A*. In acid solution the spectrum changes to that shown in Fig. 1, curve *B*.

On irradiation with X-rays in aqueous solution (ref. 3 and unpublished work by the authors and Swallow) containing 0·5 *M* ethanol and approximately $10^{-3}$ *M* nicotinamide-N′-propyl iodide, another product was obtained, the spectrum of which is shown in Fig. 1, curve *C*. The product isolated was crystalline, melting point 99–103° C. Elementary analysis and oxidative titration indicated that it is a dihydro compound. In acid solution it gave a spectrum as shown in Fig. 1, curve *B*, identical in all respects with that obtained from the other product.

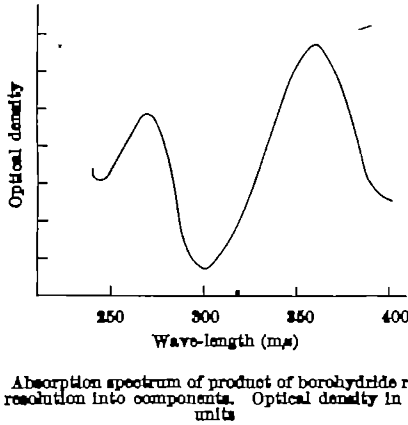

Fig. 2. Absorption spectrum of product of borohydride reduction, before resolution into components. Optical density in arbitrary units

In view of these findings, it was of interest to investigate the results of borohydride reduction. Here, in the case of coenzyme I, a product exhibiting enzymatic behaviour midway between the products obtained by the other two methods is obtained. On borohydride reduction of the nicotinamide we obtained a product having the spectrum shown in Fig. 2, a composite of the other two. From the product two pure components could be separated. One, a crystalline product having melting point 103° C., gave a spectrum like Fig. 1, curve *C*, whereas the other gave a spectrum like Fig. 1, curve *A*. Thus borohydride reduction apparently gives a mixture of the products obtained by the other two methods.

Regarding the product of electrolytic reduction, Leach[7] obtained the $E^0$ values of the product in solution, but did not isolate it. Fundamental work on the mechanism of organic electrolytic reduction processes became available recently[13], indicating that in this method radical intermediates may result.

On electrolytic reduction of nicotinamide-N′-propyl iodide in alkaline carbonate solution, a product was obtained the spectrum of which is identical with that of the radiation product and one of the borohydride products, as shown in Fig. 1, curve *C*.

We find, then, that electrolytic and radiation reduction, both of which are assumed to proceed by a free-radical intermediate, yield the same dihydro derivative. Hydrosulphite reduction, proceeding by an ionic addition intermediate, yields another dihydro derivative. Borohydride, the mode of operation of which is not entirely certain yet, but is often assumed to involve hydride ($H^-$) ions, yields a mixture of two such derivatives, which can be separated into its components.

If Pullman's[14] views are accepted and if hydrosulphite does indeed yield the same isomer as the enzymatic process, as is often assumed, then the product of these two methods would be the *para*-dihydro isomer. Two *ortho*-dihydro isomers are possible, and judging by the behaviour of the N′-alkyl nicotinamide models, Karrer thought the enzymatic product to be an *ortho*-dihydro derivative.

We hope to gain further information on this point from an investigation now in progress in collaboration with Dr. A. J. Swallow (unpublished work), whom we thank for valuable discussions and co-operation. The radiation chemical aspects of the present work and of work on some other systems of biological interest are being reported separately[11].

## Respiratory Chain Phosphorylation in Extracts of *Azotobacter vinelandii*

Respiratory chain phosphorylation has been demonstrated in crude extracts of a few bacterial species[1–4], and in one case the extract was separated into three components which were all necessary for phosphorylation coupled with the oxidation of reduced diphosphopyridine nucleotide[2]. However, the elements supporting the system of enzymes responsible for oxidative phosphorylation in bacterial cells is still unknown. The present communication describes some preliminary experiments in which a crude water-extract from *Azotobacter vinelandii* was fractionated by high-speed centrifugation into particles and 'soluble' fractions. This organism was chosen because it is strictly aerobic (cf. ref. 2) and has a very high respiratory activity.

Table 1. Oxidative Phosphorylation in Extracts of *Azotobacter vinelandii*

See text for method of preparation of fractions. In experiments 2–4, fraction *P* was washed by resuspending in 0·05 *M* phosphate, pH 7·0, and repeating the high-speed centrifugation.

Reaction mixture: phosphate, pH 7·4, 0·04 *M*; magnesium, 0·005 *M*; adenosine monophosphate, $6 \times 10^{-4}$ *M*; adenosine diphosphate, $6 \times 10^{-4}$ *M*; glucose, 0·03 *M*; versene, 0·001 *M*; succinate, 0·02 *M*, or fumarate, 0·005 *M*; hexokinase. In experiments 2, 3 and 4, fluoride (0 04 *M*) was present. Reaction volume, 1 ml., 25° C., 30 min. Δ (esterified phosphorus) and (oxaloacetate + pyruvate) measured as described previously (ref. 3)

* Dialysed against 0·05 *M* phosphate, pH 7 0, at 4° C., for 2 hr.
† Heated 100° C., 3 min., centrifuged, and supernatant used.

The extract was prepared essentially according to a procedure already described[5]. In Table 1, fraction *P* consists of particles not sedimented by 20 min. centrifugation at 10,000 *g*, but sedimented at about 120,000 *g* for 90 min. Fraction *S* is the clear supernatant taken from the top of the tube, after the high-speed centrifugation. The small particles oxidized succinate with phosphorylation, the phosphorus/oxygen (atoms) ratios varying between 0·14 and 0·87 in the experiments reported in Table 1. The reason for the wide variation between different preparations is not known; it is not due to instability of the enzyme systems in the extract, since neither the oxygen uptake nor the esterification of phosphate were affected by standing 24 hr. at 4° C. or 10 min. at 25° C. Fraction *S*, which contains proteins of molecular weight less than $10^4$, possesses considerable 'soluble' succinic oxidase activity, especially in exp. 1, with some phosphorylation. When the two fractions were mixed, both the oxygen uptake and the phosphorylation were stimulated far beyond that expected from an additive effect. The phosphorylation was usually increased more than the oxidation, so that the phosphorus/oxygen (atoms) ratio was increased.

The stimulation of the oxygen uptake is similar to an effect already described in extracts of *E. coli*[6]. It can be explained in our experiments by the ability of the supernatant to promote the oxidation of fumarate formed from the succinate. Fumarate is only very slowly oxidized by fraction *P* (exp. 3 in Table 1), so that the oxidation of succinate proceeds only a single step. However, fumarate is rapidly oxidized by the two fractions combined (exp. 4).

The increase of the phosphorus/oxygen (atoms) ratio brought about by adding fraction *S* to fraction *P* is partly explained by the fact that the proportion of the total oxygen uptake which is associated with the succinate → fumarate step, a reaction yielding relatively little phosphorylation, is decreased. However, it is unlikely that this is the complete explanation. Dialysis of fraction *S* had a marked effect on the phosphorylation, with relatively little action on the oxygen uptake. Heating fraction *S* abolished its activating effect. It is possible that fraction *S* contains soluble enzyme(s) and coenzyme(s) which may activate the relatively deficient particles in fraction *P*. This can be tested by further fractionation of fraction *S*.

The phosphorylation was only partially inhibited by dinitrophenol (Table 2). Pinchot[6] found that the phosphorylation with *A. faecalis* extracts was also little affected by dinitrophenol. It has previously been suggested[7] that the action of dinitrophenol on

Table 2. Effect of Dinitrophenol

Reaction mixture as in Table 1, with succinate as substrate and fluoride added. Fraction *P* (0·7 mgm. protein) + fraction *S* (4 8 mgm.)

| Dinitrophenol (*M*) | Oxygen uptake (μ atoms) | Δ (esterified phosphorus) (μmoles) | P : O |
|---|---|---|---|
| 0 | 4 35 | 1·74 | 0·40 |
| $3 \times 10^{-5}$ | 4 26 | 1·29 | 0·30 |
| $10^{-4}$ | 3 72 | 0 96 | 0 26 |

mitochondrial phosphorylation might be indirect. It may not be revealed in the very small particles in extracts of micro-organisms.

## Isolation of $\Delta^9$ Heptadecenoic Acid from Lamb Caul Fat

APART from the fats of dolphins and porpoises, which contain considerable proportions of *iso*valeric acid, it has been customary to regard animal fats as consisting of triglycerides of straight-chain even-numbered carbon saturated and unsaturated fatty acids. However, recent work in this laboratory has shown that there occur also trace amounts (up to 1·0 per cent) of saturated fatty acids in the form of odd-numbered *iso*-acids and *ante-iso*-acids[1], even-numbered *iso*-acids[2], polybranched acids[3] and odd-numbered straight-chain acids[4]. Odd-numbered straight-chain unsaturated acids, however, have not hitherto been found in natural fats.

Appel, Bohm, Keil and Schiller[5] have earlier shown that when synthetic fats containing odd-numbered carbon saturated *n*-fatty acids within the range $C_9$–$C_{19}$ are fed, these acids are deposited in animal fats, including the depot fats of the goat and the rat, and the milk fat of sheep. Moreover, the animal is able to desaturate these acids so that, in addition to the presence of odd-numbered saturated *n*-acids, there are also found the corresponding $\Delta^9$-unsaturated fatty acids within the range $C_{11}$–$C_{19}$ inclusive. In view of the ability of the animal to dehydrogenate odd-numbered *n*-fatty acids, it could be anticipated that having established the occurrence of uneven-numbered carbon straight-chain fatty acids in natural fats[4], the corresponding $\Delta^9$-unsaturated fatty acids would also be found. This is now confirmed by recent work in this laboratory.

The methyl esters of the liquids (1,054 gm.) prepared by crystallization three times from ten volumes of acetone of the mixed fatty acids of lamb caul fat (2,578 gm.) at − 35° were fractionally distilled *in vacuo* to yield a fraction *L*2,6, 41·5 gm., sap. equiv. 284·4, iodine value 65·8, $[\alpha]^{20^\circ}_D$ + 0·99. After removal of the more saturated constituents by crystallization of the acids (36·90 gm.) from 40 volumes of light petroleum (b.p. 40–60°) three times at − 40°, the soluble portion, 28·16 gm., iodine value 88·9, $[\alpha]^{20}_D$ + 0·44, was converted to methyl esters and subjected to repeated fractional distillation to remove the methyl esters of $C_{16}$ and $C_{18}$ acids. Eventually, there was obtained a fraction (7·94 gm.) consisting almost entirely of methyl esters of $C_{17}$-acids. Repeated low-temperature crystallization of the acids (6·68 gm.) from acetone resulted in the following fractions arranged in order of increasing solubility:

| Fraction | | Iodine value |
|---|---|---|
| 1 | 1·21 gm. | 13·4 |
| 2 | 1·05 | 72·4 |
| 3 | 1·19 | 74·7 |
| 4 | 1·03 | 80·9 |
| 5 | 1·88 | 99·2 |
| 6 | 0·532 | 119·9 |

Fractions 2, 3 and 4 were combined, and after conversion to methyl esters (3·09 gm.) were chromatographed on a 30-mm. diameter column packed with a mixture containing 106 gm. silica gel and 26 gm. of 'Celite'. Fourteen fractions were eluted with petroleum ether and the residue with methyl alcohol. Of these fractions, 1–6 were of relatively high melting point and showed optical rotation. Fractions 7–13 melted within the range of − 32° to − 30·5° showed negligible optical rotation and were therefore bulked, giving 1·846 gm. Hydrogenation of 0·30 gm. on conversion to the acid (0·25 gm.) had a melting point of 59·9–60·5°. When admixed with authentic margaric acid of melting point 60·8–61·0°, the mixture melted at 60·0–60·6°. Oxidation of 0·403 gm. with 2 gm. finely powdered potassium permanganate in acetic acid at 50° C. gave 0·078 gm. of unoxidized material. From the oxidation products insoluble in light petroleum there was obtained on crystallization from water 0·100 gm. of acidic products, melting point 102–103·5°, saponification equivalent 94·1. On admixture with authentic azelaic acid, melting point 104·5–105·5°, the melting point was raised to 103–104°. These results accord with the presence of $\Delta^9$-heptadecenoic acid in lamb caul fat.

In the present sample, the iodine values of the methyl esters of the liquids corresponding to those of $C_{17}$-acids was unusually high (65·8). In another sample of mutton tallow from older animals the iodine value associated with the $C_{17}$-fraction was of the order of 15, which suggests that the ratio of unsaturated to saturated $C_{17}$-acids shows a wide variation. In the sample under examination the iodine value of the $C_{18}$-fraction was of the order of 12 units, showing that the $C_{18}$-acids had been much less desaturated than the $C_{17}$-acids.

It is therefore concluded that, in addition to the types of fatty constituents mentioned above, it is likely from the evidence provided that there occurs also in natural fats a series of straight-chain $\Delta^9$-unsaturated fatty acids with an uneven number of carbon atoms.

## Molecular Weight of Ovalbumin and of Bovine Serum Albumin in Urea Solution

Since 1902, when Ramsden[1] described the effects of urea on "proteids", there has been much speculation regarding the molecular weights of proteins in urea solution. Some workers have claimed that aggregation does not take place in the urea denaturation of ovalbumin and bovine serum albumin. In spite of this, it is well known that their urea solutions frequently form gels when the protein concentration is high. Recently, Kauzmann *et al.*[2,3] have studied the viscosity changes accompanying the urea denaturation of these proteins and the gelling time for ovalbumin. Under certain conditions an aggregation dependent upon concentration occurred, and this was interpreted in terms of hydrogen bonding and intermolecular disulphide bonds (the latter through the —SS— and —SH exchange reaction of Huggins, Tapley and Jensen[4]).

During the past three years, a physicochemical study has been made in this laboratory of proteins in urea solution. Observations on sedimentation and diffusion for ovalbumin and bovine serum albumin are briefly reported here. Data for the denaturation of 1 per cent (w/v) protein in 7 *M* urea (with buffer and sodium chloride to Γ/2 of 0·1) at 25° C. are summarized in Table 1. Sedimentation coefficients (*s*) and diffusion coefficients (*D*) are given in C.G.S. units and have been multiplied by $10^{-13}$ and $10^{-7}$ respectively, and refer to the urea solvent at 25° C. unless otherwise stated. Where molecular weights have been calculated, the partial specific volume was taken to be the same as the native protein (the justification for this will be given elsewhere). The molecular weight of native ovalbumin was determined to be 39,000 ($s_{20,w}$ = 3·11, for 0·5 per cent; $D_{20,w}$ = 7·67) and bovine serum albumin 68,000 ($s_{20,w}$ = 4·07, for 1 per cent; $D_{20,w}$ = 5·49) in agreement with other workers[5].

Table 1. SEDIMENTATION AND DIFFUSION

| Ovalbumin | | Serum albumin | |
|---|---|---|---|
| *p*H | Homogeneity | *p*H | Homogeneity |
| 3·3 | Homogeneous. No aggregation. *s* = 0·66 ($s_{20,w}$ = 1·36). *D* = 2·33. Mol. wt. = 42,000 | 3·6 | Homogeneous. No aggregation. *s*, *D* will be discussed elsewhere |
| 6·2 | Heterogeneous. Progressive increase of faster components with time. *s* = 0·8 and 2·1 to 4·5 (peaks diffuse) | 6·4 | Homogeneous. No aggregation. *s* = 1·20 ($s_{20,w}$ = 2·43). *D* = 2·21. Mol. wt. = 71,000 |
| 9·4 | Heterogeneous. *s* = 0·8 and 1·5. Sedimentation peaks diffuse. Aggregation not eliminated by —SH reagent but sedimentation peaks sharpened | 9·5 | Very little aggregation after 4 hr. reaction. Increasing heterogeneity after 26 hr. Aggregation eliminated by —SH reagent |

The results in Table 1 (supported by optical rotation studies) suggest that unfolding (or swelling) of these proteins occurs in urea solution. At certain *p*H values this is followed by aggregation.

The extent to which the aggregation reaction could be blocked by cysteine and *p*-chlormercuribenzoate was also investigated. At *p*H 6·7, 0·02 *M* cysteine had no effect on the aggregation of ovalbumin in 7 *M* urea, in accordance with expectation (cf. ref. 2, p. 5169); at *p*H 8·3 it caused considerable sharpening of the two sedimentation peaks. The effect of 0·005 *M* *p*-chlormercuribenzoate at *p*H 9·1 was similar. The molecular weight of the aggregate in the presence of the —SH reagent was estimated to be 150,000–250,000 and therefore consists of four to six molecules of ovalbumin. The behaviour of serum albumin in the presence of —SH reagent was quite different. At *p*H 9 the protein was homogeneous by sedimentation and diffusion. The molecular weight (60,000, *s* = 0·98 and *D* = 2·33) was virtually the same as the native protein.

Considering our results with the previous work[2,3], there are evidently at least two kinds of aggregation reactions possible for ovalbumin in 7 *M* urea. The exchange reaction of —SS— and —SH groups seems to be less important than the other one (probably hydrogen bonding[3]). In the case of bovine serum albumin, aggregation only occurs through the exchange reaction. Further details of the results for these and other proteins will be described elsewhere.

## Some Differences in the Effects of Different Sympathomimetic Amines on the Isolated Innervated Rat Diaphragm Preparation

When the electrically stimulated contractions of the isolated innervated rat diaphragm preparation are depressed by extra potassium chloride in Krebs solution, addition of adrenaline produces recovery[1,2]. Further, when mixtures of adrenaline and potassium chloride are added to preparations already depressed by extra potassium, 0·2 μgm. adrenaline antagonizes as much as 5 mgm. of the chloride[2]. The approximate amounts of twelve different sympathomimetic amines needed to antagonize in this way 5 mgm. potassium chloride have now been found; they are shown, relative to adrenaline as unity, in Table 1, together with the formulæ of the amines.

Unexpectedly, 500 μgm./50 ml. methedrine hydrochloride, or 800 μgm. amphetamine sulphate, increased rather than reduced the depression due to potassium chloride, and with larger doses (2–5 mgm.) of methedrine or benzedrine the increase was very rapid. 500 μgm. pholedrine or tyramine had no visible effect within 5 or 10 minutes. When added alone, the different doses of the different sympathomimetic amines required to antagonize 5 mgm. potassium chloride did not produce equal amounts of recovery; the amines which antagonized less potassium chloride than adrenaline generally pro-

* I am grateful to Bayer Products, Ltd., for a gift of this compound.

duced larger recoveries than might have been expected from these antagonisms. For example, although about 2,500 times as much ephedrine as adrenaline is needed to antagonize 5 mgm. potassium chloride, about 100 times as much ephedrine as adrenaline produced equal recovery. This may be due to a slower rate of recovery produced, for example, by ephedrine.

Adsorption of adrenaline at specific receptor surfaces probably occurs prior to its effect on the contractions[3,4]. Preliminary attempts have been made to determine the amount of this adsorption: ½–2 min. after adding 1–5 μgm. adrenaline to a 50-ml. bath in which a rat diaphragm was suspended, 1–5 ml. solution was withdrawn and adrenaline estimated in the solution by the ethylene diamine method[5], without prior passage of the solution over alumina; 10 per cent of the adrenaline had disappeared from the solution. As adrenaline is not differentiated from adrenochrome when alumina is not used, the 'losses' of adrenaline may have been due to its transfer to the muscle rather than to its oxidation. If this is the case, and if the volume of the surface phase of the preparation is taken, with various assumptions[3], as $10^{-8}$ ml., the ratio of the concentrations of adrenaline in the surface and bulk phases of the solution would have averaged $10^3$–$10^4$, a figure in reasonable agreement with the minimum value $(2 \times 10^3)$, calculated from theoretical considerations by Danielli[3]. The amines with the most OH groups are the most effective in antagonizing potassium chloride and in producing recovery; this influence of polar groups is presumably related to the chemical configuration of the receptors.

Experiments carried out with the rat diaphragm preparation in normal Krebs solution and in solution containing only 0·5 m*M* calcium ions show that in these solutions the effects on the contractions due to methedrine and benzedrine are the same in direction as those of 2 μgm./50 ml. adrenaline, but are more prolonged; thus, 4–6 mgm. methedrine or benzedrine augmented the contractions in normal Krebs solution; in 400 μgm. doses they had no effect. In the solution low in calcium ions, there is partial neuromuscular block and this is temporarily increased by 2 μgm. adrenaline[6,7]; a subsequent 50-μgm. dose facilitates transmission[7]. Increased block was produced in varying amounts by other amines; for example, 4 mgm. methedrine or 6 mgm. benzedrine rapidly and completely blocked neuromuscular transmission and, also like adrenaline, slightly depressed the response to direct stimulation; unlike adrenaline, these effects were prolonged. 1 mgm. methedrine produced a slower block; no facilitation has so far been observed with these amines.

Obviously the depressant effect of 500 μgm./50 ml. methedrine in muscles depressed by extra potassium chloride, in which adrenaline produces recovery, cannot be due to prolonging of the action of adrenaline, and it is very unlikely to be due to the fairly high dosage of methedrine used: larger amounts of ephedrine augment the contractions in these circumstances, as do larger doses of methedrine in normal Krebs solution. It is even more unlikely that methedrine acts in a very different way from adrenaline on skeletal muscle. It is possible that the sometimes different effects of adrenaline and methedrine might be due to some difference in a single reaction; it is more probable, however, that redistribution of potassium[8] and of calcium[7], and other changes affecting the contractions which are produced by adrenaline, are the resultant of more than one reaction, chemical or physical, brought about by adrenaline. Further work with different sympathomimetic amines should be of interest with regard to the mechanism of action of these drugs.

## Single-Breath Continuous Carbon Dioxide Analysis

MEASUREMENTS of inequalities in alveolar ventilation and of physiological dead space give an estimate of the under-ventilated and under-perfused volumes of diseased lungs. Comroe and Fowler[1] described the use of a nitrogen meter to detect uneven alveolar ventilation during a single expiration. Dubois *et al.*[2] showed how the physiological dead space could be assessed by measuring the carbon dioxide content of expired air with a rapid infra-red gas-analyser, and Dornhorst *et al.*[3] described the pattern produced, with similar apparatus, by emphysematous patients. This method relates the carbon dioxide content of expired air to time, and the records produced are sometimes difficult to interpret because the carbon dioxide content is also influenced by the volume of air expired. Marshall *et al.*[4] demonstrated the relation between volume and carbon dioxide content of expired air by fractional analysis and applied their method to normal and diseased subjects.

We have modified the method of Dornhorst *et al.*[3] so as to plot directly the carbon dioxide content against the volume expired. The expiratory flow-rate is also demonstrated. A single expiration is made into a Benedict spirometer which has a potentiometer attached to the pulley. The change in volume is displayed on the horizontal axis of a cathode-ray oscilloscope trace. The spot of the oscilloscope is at the same time influenced in the vertical axis by a 6-c./sec. a.c. signal from an infra-red carbon dioxide analyser. This is fed with air which is taken from just beyond the mouth, circulated through the analyser, and returned to the spirometer by a small electric pump. The graph of carbon dioxide content against volume for one expiration is photographed on a stationary film. The delay of the analyser can be reduced to one-third of a second and can be allowed for in reading the records, being represented by two strokes of the a.c. signal.[2]

The normal record (Fig. 1) consists of a horizontal line representing dead space, followed by a rapid rise to a flat plateau of alveolar air. The abnormal record, illustrated in Fig. 2, is from a patient with advanced pulmonary fibrosis and emphysema. It can be divided into three phases: the horizontal initial line; a steeply sloping portion from poorly perfused lung, the volume of which can be substantially reduced by holding the breath beforehand, and from which physiological dead space can be estimated; and finally, a gently sloping portion which is very similar to the records obtained by Comroe and Fowler[1,4] and therefore probably reflects uneven alveolar ventilation. In other patients with emphysema, the horizontal phase may be followed by a rapid rise to the final sloping phase.

It causes the subject very little discomfort or inconvenience to obtain such a record, and the apparatus is commercially available. Abnormalities are immediately recognizable and the a.c. signal provides a time-scale from which the expiratory flow-rate can be calculated.

We are comparing records so produced with other methods of estimating pulmonary function and are planning to make records from the two lungs separately through a Carlens catheter.

We are grateful to the Gateshead Hospital Management Committee for the purchase of the apparatus, to the Newcastle Regional Board Research Committee for a grant for technical assistance, and to Mr. J. T. Kennair, who gave much technical advice. The carbon dioxide analyser was supplied by the Infra-red Development Co., Ltd.

## Inhibition of the Production of Precipitating Antibodies in Young Rabbits

THE failure of rabbits to develop antibody to bovine serum albumin when injected with this antigen at an early age was recently reported by Hanan and Oyama[1]. Similar results have been reported by Buxton[2], who found there was no antibody response to killed *Salmonella pullorum* in fowls after they had been exposed to this organism as embryos and young chicks. The studies of Hanan and Oyama[1] suggest that the responses to closely related antigens may also be impaired in rabbits that exhibit inhibition. If, however, rabbits that failed to develop antibodies to one antigen were capable of producing antibodies to a closely related one, the value of such antisera in systematic serology and similar fields would be apparent. Preliminary results of pre- and post-natal exposure of rabbits to parenteral administration of whole chicken serum are reported in this communication.

Two pregnant rabbits were obtained thirty days before term, and twice weekly each was injected subcutaneously with chicken serum. The young consisted of five (litter I) and six (litter II) rabbits. The young rabbits in each of the litters were divided into three groups.

Group *A* were killed and bled the day after they were born.

Group *B* were given post-natal injections of chicken serum before they were four months old (mature). Subcutaneous doses of $\frac{1}{2}$ ml. of antigen were injected three times weekly for four weeks. The rabbits from litter I were first injected four days after they were born. The rabbits from litter II were not given the first injection until they were five weeks old.

Group *C* were given post-natal injections of chicken serum after they were mature. The schedule of injections for this group was the same as given to group *B*.

Table 1

| Litter | Group | Titre | Anaphylaxis |
|---|---|---|---|
| I | *A* | 0 | none |
| II | *A* | 0 | none |
| II | *A* | 0 | none |
| I | *B* | 0 | none |
| I | *B* | 0 | none |
| II | *B* | 1 : 1,500 | severe |
| II | *B* | 1 : 2,500 | mild |
| I | *C** | 1 : 2,500 | fatal |
| II | *C* | 1 : 12,500 | fatal |
| II | *C* | 1 : 25,000 | not attempted |

* One rabbit in this group died before post-natal injections were administered.

All the injected rabbits were bled two weeks after he first injection and again after four weeks. The serum from each blood sample was separated for nterfacial 'ring' precipitin tests with dilutions of chicken serum in neutral physiological saline. The antibody activity of the rabbit serum was also tested for ability to induce passive anaphylaxis in guinea pigs. The guinea pigs were injected intravenously with 1 ml. of undiluted young rabbit serum and after 44–48 hr. were challenged with 1 ml. of chicken serum.

The results (Table 1) indicate that, in rabbits exposed pre-natally to chicken serum antigen, antibodies are not present at birth; but, if post-natal injection of antigen is delayed for five weeks after birth, antibodies do form. Burnet[3] has recently reviewed instances in which pre-natal exposure alone was sufficient to inhibit antibody production in mice to lymphocytic choriomeningitis virus and in a human being to *A* and *O* blood groups. The inhibition may be related to the presence of gamma globulins, which have been reported not to appear in the electrophoretic pattern of rabbits until they are six weeks old[1].

When the rabbits of group *B*, litter I, were four months old, they were still incapable of antibody response to repeated injections of chicken serum. When subcutaneous injections of bronze-turkey serum were given, however, the serum of one of the rabbits reacted to a titre of 1 : 2,500 and the serum of the other to a titre of 1 : 100 with dilutions of turkey serum in physiological saline. In precipitin tests with normal antisera produced in rabbits, turkey and chicken serum antigens show strong cross-reactions; but no cross-reaction was observed when the antiserum produced with turkey serum in the pre- and post-natally injected rabbits was tested with chicken serum.

These findings suggest that antisera produced by this method may be of considerable use in specific detection of avian bloods by the precipitin test. Adaptation of the method to the serological detection of bird bloods in hæmatophagous insects is being studied.

I thank Prof. A. S. West, professor of zoology in Queen's University, Kingston, Ontario, for helpful suggestions, and Dr. J. McLintock, Entomology Division, Ontario, for advice during preparation of the manuscript.

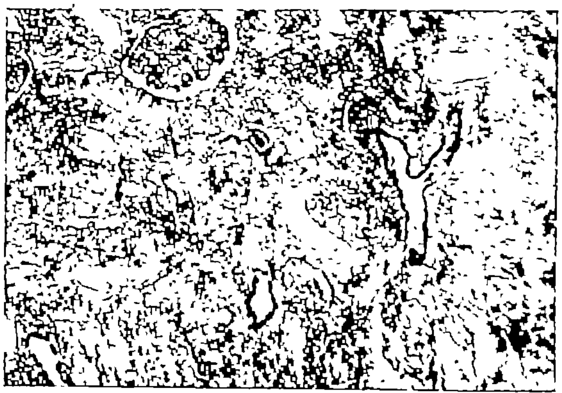
## Mucins in the Epithelium of Renal Collecting Tubules

As an incidental finding to a study of the staining of elastic tissue carried out by one of us[1], the luminal borders of the epithelium of the collecting tubule in the kidney of the guinea pig were observed to stain intensely by Gomori's aldehyde–fuchsin method[2] (Fig. 1). We have been unable to find in the literature any previous report of selective staining of the collecting system in the mammalian kidney.

Attempts have been made to interpret the significance of aldehyde–fuchsin staining[3], but little is known yet about its specificity or mode of action. Various other stains were therefore applied to characterize the reacting material. The same sites were demonstrated by a number of methods frequently used to stain mucins (Table 1), and the material is therefore presumed to be related to this general group. Krause[4] has noted the presence of mucins in the collecting system of the dove (*Columba livia domestica*) and lizard (*Lacerta agilis*).

To assess species distribution, kidneys of man, monkey (*Macaca mulatta*), dog, cat, pig, rabbit, rat, mouse, hamster, squirrel (*Sciurus carolinensis*), opossum (*Didelphis virginiana*), chicken, turtle (*Terrapine carolina*), frog (*Rana catesbiana*), toad (*Bufo marinus*), salamander (*Amblystoma maculatum*), goldfish (*Carassius auratus*), and toadfish (*Opsanus tau*) were examined. Materials stained by these various methods (Table 1) have been observed throughout the collecting tubules of the chicken



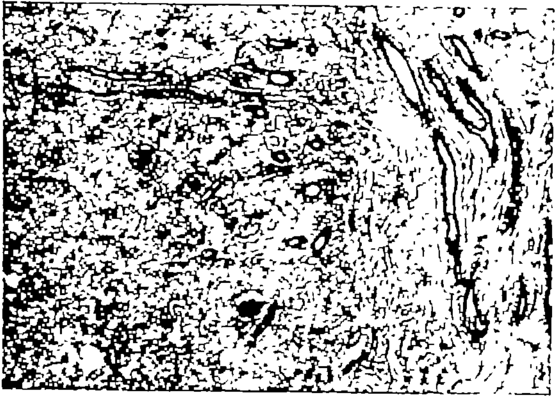


Fig. 1 (*Above*). Terminal ramifications of the collecting ducts in the kidney cortex of guinea pig. Aldehyde–fuchsin staining. × 150

Fig. 2 (*Below*). Arborization of collecting ducts in lobular papilla of kidney in chicken and dispersion into lobule proper Hale reaction. × 70

Table 1. STAINING PROPERTIES OF THE MUCINS OF COLLECTING TUBULES

| Aldehyde–fuchsin | 4+ | 4+ | – | 2+ | — |
| Hale | 4+ | 4+ | 4+ | 4+ | 4+ |
| Periodic–Schiff | ± | 2+ | 2+ | 3+ | 2+ |
| Mucicarmine | 1+ | 1+ | ± | 1+ | – |
| Mucihæmatin | 1+ | 1+ | 1+ | 1+ | – |
| Metachromasia (thionin) | ± | ± | – | – | – |

(Fig. 2), turtle and toadfish ; and in goldfish, numbers of mucous goblet cells have been found in some of the larger ducts.

The occurrence of such materials in the fish–reptile–bird sequence agrees with Krause's experience and is not remarkable ; but the case of the guinea pig remains a phyletic curiosity. It is of interest to note also that, despite their homologous origins, the collecting tubule mucin of each of these species is histochemically distinct.

## A *Glossopteris* bearing Sori-like Structures

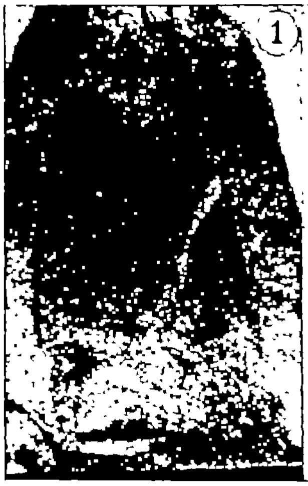
IT had been indicated by Feistmantel[1] that some species of *Glossopteris* bear sori in one of the following patterns, namely, in longitudinal rows (Indian materials), along the veins (Australian materials) and along the margin (Indian materials). Unfortunately, these structures were not well recognized in the subsequent literature on fructifications assigned to *Glossopteris*. Recently, an undetermined species of *Glossopteris*, bearing sori-like bodies (Fig. 1) as described by Feistmantel[1,2], has been collected from the Middle Permian (Barakar) in the Central Province of India. The specific determination of the specimen was not possible because its upper half only is preserved and the venation (excepting the midrib) is not always distinct. The rock bearing the fossil is a piece of soft greyish shale.

The sori-like bodies (1·2–2 mm. in diameter, Figs. 1 and 2) are usually round, slightly thickened spots, sometimes oval, and often coalesced and compressed laterally into irregularly linear structures along the margin of the frond. A number of individually recognizable sor like structures are also present on the margi These sori-like spots are mostly concentrated on th upper portion of the fossil, the lowermost portio being almost sterile. The supposedly fertile bodies a arranged (1) more or less along the main divergin lateral veins, and (2) also along the margin of th frond. They are not usually equidistant from on another. Those near the margin of the frond a bigger than those near the midrib. A few of the were examined, but unfortunately they did not yiel any spore or spore case.

It is very striking that in the present specimen th arrangement of sori-like bodies follows two distinc patterns of distribution (both along the veins an the margin), which have not been found hithert to occur in the same frond or fronds belonging t the same species[1] as in the present case. So the are at least four types of sorus arrangement in th genus *Glossopteris*, including the three types pre viously described by Feistmantel[1,2], "which b analogy with living ferns would represent as man different genera, belonging even to quite differen families"[1]. The fern-like arrangement of the sori(-lik bodies) on the *Glossopteris* fronds as described i this communication and by Feistmantel[1,2] is undoubtedly one of the most primitive types so fa known among the seed plants. Feistmantel[1] suggested the need for a generic separation o *Glossopteris*, and I formed the same opinion whe describing[3] several types of isolated cutinized micro sporangia (from macerated Indian Lower Gondwan coal) referable to *Glossopteris*. These microsporangi are of different shapes and sizes, and there may b at least two types of dehiscing mechanism. It i however, premature to suggest any generic separatio of the *Glossopteris* unless more data are available.

Whether the sori-like bodies described by Feist mantel[1,2] and by me here, and the isolated micro sporangia previously described by me[3], are the sam structures has yet to be established. However, th size and shape of the latter indicate that they ca be accommodated in the sori-like structures describe in this communication.

The manner in which the sori-like structures ar borne on the *Glossopteris* frond indicates that th



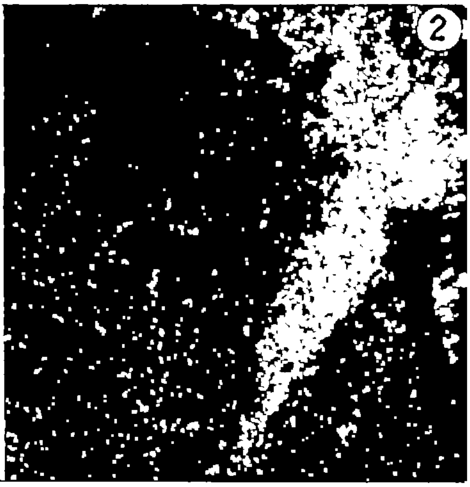


Fig. 1. *Glossopteris* frond showing sori-like structures along the margin and also more or less along the main lateral veins diverging from the midrib. Less than ½ nat. size
Fig. 2. Part of the *Glossopteris* frond showing magnified view of solitary and coalescent sori-like structures. × 3

mus probably belongs to the primitive Pteridosperms, and should be regarded as closely related to ie ferns. But on the basis of the new interpretation[4] f the recently discovered ovulate organs of *lossopteris*, it has been suggested that the genus elongs to an unknown or imperfectly known ymnosperm rather than to the Pteridosperms. discussion of the problem will be published elsehere.

I am indebted to Mr. S. K. Ghosh, geologist in ne Sohagpur coalfield, for the material, and to Mr. . C. Bhattacharya, of the Zoology Department of his University, for photographing it.

## Significance of the Subdermal Space in Pelagic Fish Embryos and Larvæ

Fish eggs can be divided into two main groups, lemersal and pelagic, according to their buoyancy. Most freshwater and some marine eggs fall into the first category; truly pelagic eggs, on the other hand, are mainly marine. Certain freshwater fish, the 'bubble blowers', contrive to float off their eggs with an extrinsic mechanism; the egg itself is denser than water.

Between pelagic and demersal fish embryos there is a noticeable and consistent difference in the size of the marginal fin during early life (Fig. 1). The large fin of the pelagic embryo is formed late in egg development by the separation of the thin integument from the underlying mesoderm of the larval axis. There are no supporting structures in the walls of the fin, which must therefore be extended, in life, by turgor within the lumen. The lumen is a subdermal space, filled according to McIntosh and Prince, with "a jelly-like lymph"[1].

The development of voluminous subdermal spaces in fish embryos is clearly related to the pelagic habit. The immature egg of the plaice sinks in sea water. At maturation within the ovary, the egg is distended by a gross intake of ovarian fluid which dissolves the yolk spherules and gives the egg its buoyancy. The ionic composition of this yolk diluent resembles that of adult blood, as indicated by the observations of Milroy[2] and Dakin[3]. It follows that a pelagic marine egg, like the parent, is in constant danger of desiccation under the osmotic gradient; loss of buoyancy is a sure sign of unhealthiness.

If McIntosh and others were correct in describing the egg capsule as porous and freely permeable to salts and water, then osmotic work must be done by the integument of the embryo to prevent an increase in body chloride and a decrease in water content. If enough water is lost, the egg will sink, irrespective of whether it has an oil globule or not. It is a fact that healthy plaice and cod eggs remain buoyant throughout embryonic life in aquaria, even though their degree of reserve buoyancy is not excessive. In 1954, for example, a batch of floating plaice eggs, fertilized in 35 parts per mille sea water, were not buoyant in 32 parts per mille sea water.

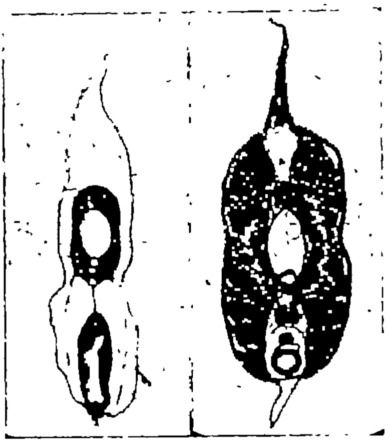

Fig. 1. Transverse sections through the trunk of a 2-day old pelagic plaice larva, × 55 (left), and a 4-day old demersal trout larva, × 30 (right), to indicate a major difference in the extent of the subdermal space

There is no known mechanism for water acceptance by the plaice embryo, from the time of liberation to the point when the mouth and anus open at hatching. One can assume, therefore, that sufficient water to preserve buoyancy must be retained within the embryo; in other words, the overall volume enclosed by the embryonal integument can only decrease within the limit laid down by the initial reserve buoyancy. As soluble nutrients from the fluid yolk are used in tissue synthesis and respiration, the remaining yolk diluent accumulates beneath the integument, separates it from the compact axial structures, and thus forms the subdermal space. The problem of water conservation does not arise in a demersal freshwater fish embryo. One can therefore readily understand the lack of subdermal space in this group and, hence, the ill-developed marginal fin.

The lumen of the marginal fin is not the only subintegumental space in the pelagic embryo and larva. It is not generally known that pelagic marine eggs, unlike demersal freshwater forms, have no circulatory system of capillaries around the yolk. These capillaries develop in the extra-embryonal mesoderm between the periblast layer of the yolk-sac proper and the extra-embryonal ectoderm. Meek[4] observed, during gastrulation in the pelagic egg of the cod,

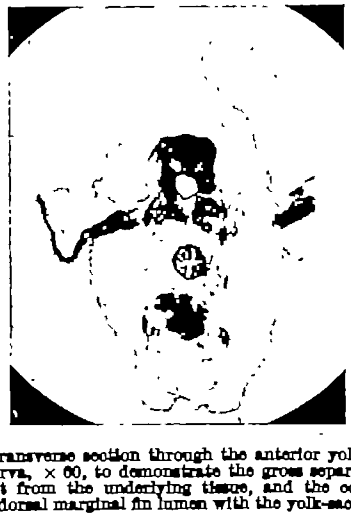

Fig. 2. Transverse section through the anterior yolk-sac region of a cod larva, × 60, to demonstrate the gross separation of the integument from the underlying tissue, and the continuity of the dorsal marginal fin lumen with the yolk-sac sinus

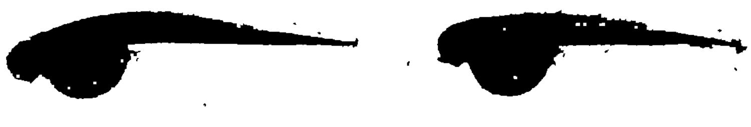

Fig. 3 Newly hatched plaice larvæ, × 7, with heavy coagulation of plasma proteins in the dorsal and ventral spaces of the marginal fin, after fixation in Heidenhain's Susa

that the extra-embryonal mesoderm rapidly breaks down into isolated mesenchyme cells, to form another sub-integumental space, the yolk-sac sinus, into which the sinus venosus of the heart opens directly. At some stage in embryonic development, the yolk-sac sinus is put in lateral communication with the lumen of the growing marginal fin. The connexion persists well into the larval stage (Fig. 2), until most of the yolk is lost. Nutrient yolk derivatives thus have easy access to embryonic and larval tissues via the subdermal spaces (Fig. 3).

There is therefore, in pelagic fish eggs and larvæ, an unorthodox extension of the primary method of direct yolk appropriation, independent of a blood vascular system. This is, undoubtedly, a result of the formation of subdermal spaces, dictated by the requirements of buoyancy and water conservation. A full account of this work will shortly be published elsewhere.

## Preparation of Cell Suspensions from Plant Roots for Cytological Studies

A CONSIDERABLE amount of microscope work involved in cytological studies of plant roots can be obviated by the preparation of a c suspension from a number of root the cell suspension can then be e ammed instead of a large number sections or squashes of individu roots. This is of particular advan age in studies in which the examin tion of a large cell population required for the evaluation of t cytological effects of a particul experimental treatment, such as X-radiation. number of techniques have been described for makin cell suspensions from plant roots[1–3], all of whic either produce a large number of broken cells or r quire the use of enzymes. The following simplifie method without the use of enzymes has given sati factory results with *Vicia faba* root-tips, the numb of cells broken being negligible.

The root tips are fixed overnight in a mixture acetic acid and ethanol (1 : 3 v/v), washed for on hour in several changes of tap water and distille water, and hydrolysed in *N* hydrochloric acid a 60–63° C. for ten minutes. This hydrolysis soften the intercellular matrix sufficiently to allow th subsequent mechanical separation of the cells; i also serves as the essential preliminary step for stain ing the nuclei by Feulgen's method. The temperatur used in this procedure, slightly higher than is usuall employed in the Feulgen technique (60° C.), does no impair the staining of nuclei as judged by eye wit the microscope. After hydrolysis the roots ar stained by the usual Feulgen procedure. The tip are then transferred to 45 per cent acetic acid (1 ml acid/10 roots) and broken up into a cell suspensio by being drawn into and out of a 5-ml. syring through a serum needle (gauge 0·8 mm.). After thre minutes of such treatment, 70 per cent of the cell are in groups of 1–4 cells, 80 per cent in groups o 1–8 cells. The number of broken cells, shown by free nuclei and empty cell walls, is less than 4 per cent. Maceration even for a further two minutes doe not increase the number of broken cells.

Groups of beans macerated by this method giv the same value for the number of cells per root tip a

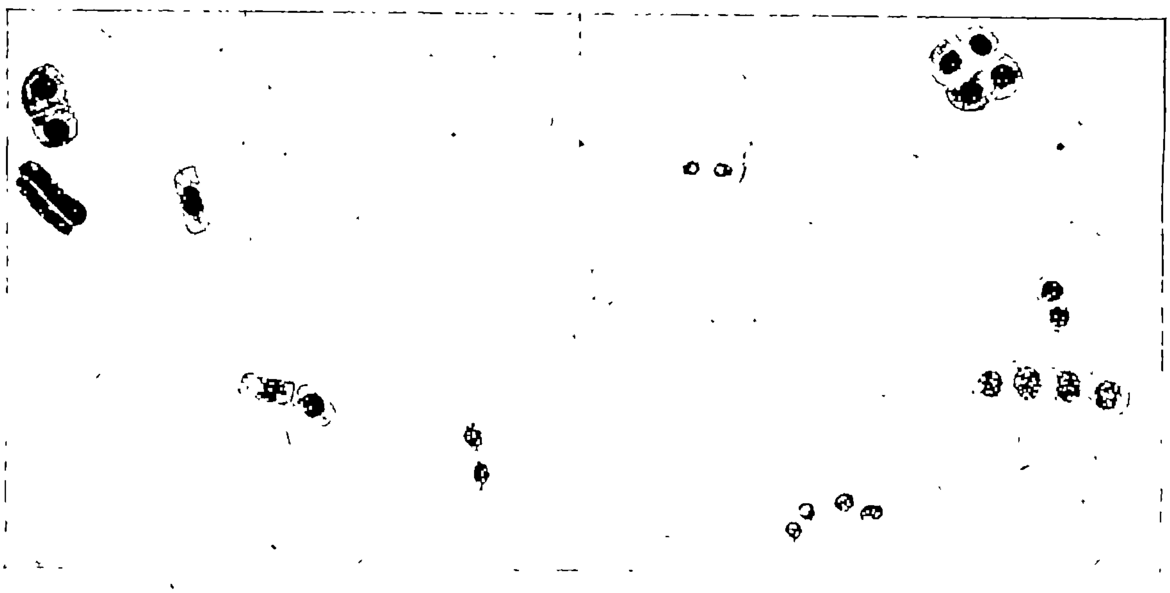

Fig. 1. Meristematic cells of *Vicia faba* roots macerated by the method described, stained by Feulgen's method and counter-stained with light green (× 160)

en they are macerated by the chromic acid tech- que of Brown and Richless[4]. Maceration is not so mplete in the fully differentiated region of the root it is in the meristem, because in that region, rticularly in the case of epidermal cells, the root nds to break into sheets of cells.

The technique has been used successfully in studies cytological abnormalities caused by X-irradiation *Vicia faba* roots, the results of which will be ported elsewhere.

## Stoichiometry of Inclusion Compounds

A RECENT study[1] of the formation of a variety of clusion compounds by potassium benzene sulphon- e led to the conclusion that it could form zeolitic ructures in the interstices of which various species uld be intercalated. Such structures would give angmuir-type intercalation isotherms[2,3], but the hole isotherm course would not necessarily be alizable because, when the content of included olecules fell below a certain limit, the zeolitic ructure may become metastable and collapse into sorbate-free but more compact crystal lattice of otassium benzene sulphonate.

While most aspects of the behaviour could be plained in terms of the above view, and of current eatments of nucleation and crystal growth, one ature remained not fully accounted for. All the clusion compounds were formed by bathing crystals f outgassed potassium benzene sulphonate in vapours f various organic species. Usually, at a critical lative pressure, nucleation of crystal growth of the clusion compound occurred, and reaction rapidly ent to completion at this pressure. Thereafter rther increases in pressure produced little or no rther change in the content of the intercalated ecies. Moreover, the amount of the intercalated ecies was often very sensitive to the temperature, ut non-stoichiometric in quantity (Fig. 1). We will

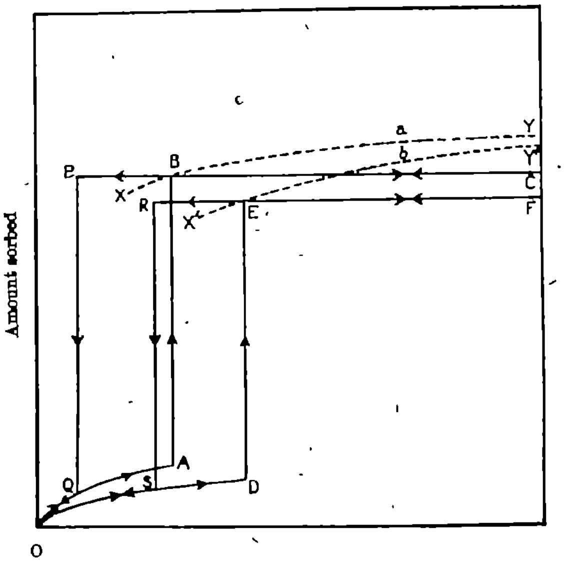

Fig. 2. Expected course of isotherms for the formation of clathrate-type inclusion compounds at temperatures $T_1$ and $T_2$ (full lines), compared with true equilibrium course (dotted lines)

consider these pressure-independent, temperature-sensitive, non-stoichiometric phases.

We may call the open lattice of the framework-forming constituent in the complex the 'host lattice'. We need for our purpose to distinguish at least two categories of inclusion compound: (1) in one group the host lattice is stable whether or not it contains included molecules (for example, tectosilicates such as certain of the crystalline zeolites); (2) in a second group the host lattice becomes metastable when the included molecules are at too low a concentration, and tends to collapse into a new phase, as with urea-hydrocarbon adducts, quinol clathrates, and complexes formed by potassium benzene sulphonate.

In both classes of inclusion compound, the true equilibrium content of intercalated molecules varies continuously with the ambient concentration of these[2,3], so that the phases are in general non-stoichiometric over the observable ranges of formation (Fig. 2, curves *a* and *b*). In the second group of inclusion compounds, however, the included molecules may be, and often are, quite immobile. Once the compound has formed, their number cannot then be increased or decreased, because the interstices containing included molecules have no exits wide enough. This circumstance will explain as follows the situation referred to earlier in connexion with the inclusion complexes of potassium benzene sulphonate.

In Fig. 2, $XY$, $X'Y'$ represent the only parts of the true equilibrium occlusion isotherms of an intercalated species at temperatures $T_1$ and $T_2$ respectively ($T_1 < T_2$), which are at least theoretically realizable without instability of the host lattice. When outgassed potassium benzene sulphonate is bathed in vapour of, say, naphthalene, the inclusion complex cannot form until the pressure at $T_1$ exceeds the value corresponding to the point $X$. Even here it will not normally

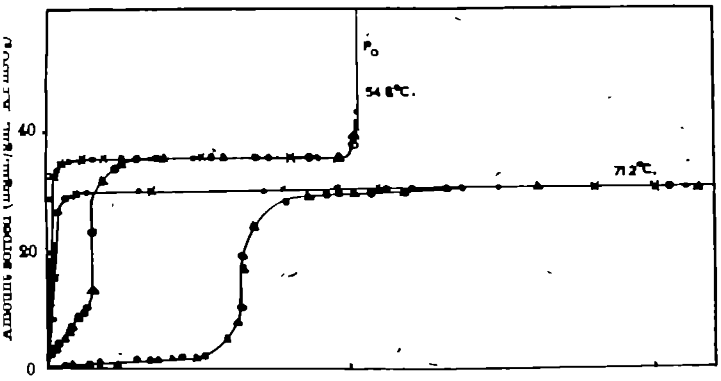

Fig. 1. Sorption isotherms for naphthalene in potassium benzene sulphonate: ○—⊙—, first sorption; ●—●—, first desorption; Δ—Δ—, second sorption; ×—×—, second desorption

form until nucleation has set in at some higher pressure, owing to difficulties in nucleation of the new zeolitic phase on or in a matrix of the naphthalene-free phase. For similar reasons, the ideally vertical section such as in Fig. 2 may also be replaced by a curve (Fig. 1)[1]. The isotherm path followed is initially *OA*, corresponding to a limited physical sorption upon external crystallite surfaces. At *A*, nucleation occurs, and a host lattice with an amount of intercalated naphthalene corresponding to point *B* is formed—a point on the true equilibrium isotherm *XY*. At *B* reaction is complete. As noted in the previous paragraph, it is assumed that no more naphthalene can now enter or leave the complex, which thus remains of fixed composition however the pressure afterwards changes over the entire range of existence of the complex. On lowering the pressure, the range of existence persists to the metastable point *P* again owing to difficulties in nucleation of crystals of the original outgassed potassium benzene sulphonate on or in a matrix of complex. At point *P* nucleation occurs, and the path *PQO* is followed. Thus, at $T_1$ the isotherm realized is *OABO* on the increasing pressure run and *OBPQO* on the decreasing pressure run.

At temperature $T_2$ ($> T_1$) exactly similar considerations apply and the isotherm realized is *ODEF* with increasing pressures and *FERSO* with decreasing pressures. Clearly, then, *PBO* and *REF* represent two non-stoichiometric phases, metastable except at *B* and *E* respectively, of composition independent (within the existence limits) of pressure, but for normal isotherms *XY*, *X'Y'*, sensitive to temperature. This behaviour was observed with the benzene, toluene, *o*-, *m*-, and *p*-xylene and naphthalene inclusion complexes in which potassium benzene sulphonate formed the host lattice[1].

In the paper[1] referred to, not all the results fall into the above pattern. X-ray data indicated more than one crystallographic structure among the complexes, and sometimes Langmuir isotherms were indeed realized, apparently without hysteresis (for example, ethanol, pyridine and ethylamine complexes).

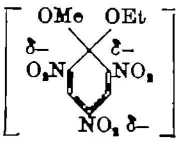
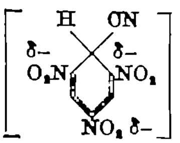
## Visible Spectrum of Potassium Ethyl 1-Methoxypicrate and of Related Compounds

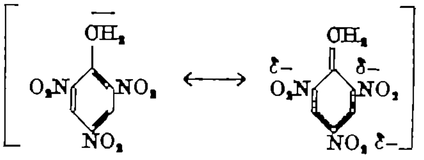
The structure of the product obtained by Meisenheimer[1] from potassium methoxide and *s*-trinitroanisole and from potassium ethoxide and *s*-trinitrophenetole which depended on these two products being identical has been confirmed by infra-red spectroscopy[2]. The product appears to be the ion (I). The visible spectra of the products obtained from these two reactions have now been measured. The spectra are identical. There are three maxima in the region 390–600 mμ, namely, at 420 mμ ($\varepsilon = 27,000$); at 478 mμ ($\varepsilon = 16,500$); and at 494 mμ ($\varepsilon = 17,000$).



(I)



(II)



(III)

Hantzsch and Kissel[3] obtained a solid from th interaction of a concentrated aqueous solution o potassium cyanide and a concentrated alcoholic solution of *s*-trinitrobenzene. To this solid Meisenheimer assigned a structure corresponding in more moder terms to (II). This solid has been re-prepared an its spectrum in acetone has been found to be featureless; in no way does it correspond to the spectrur of (I). *s*-Trinitrobenzene gives a red colour wit potassium cyanide in damp acetone solution, and i ethyl alcohol solution. The spectrum of this mixtur in the region 390–600 mμ is very similar to that o potassium ethyl 1-methoxypicrate (I). This suggest that with *s*-trinitrobenzene and potassium cyanide a compound of structure (III) is at first formed i solution. Solutions are stable for at least 48 hr. if kept away from light. However, when expose to light, the spectrum changes to a featureles spectrum more closely resembling the spectrum o

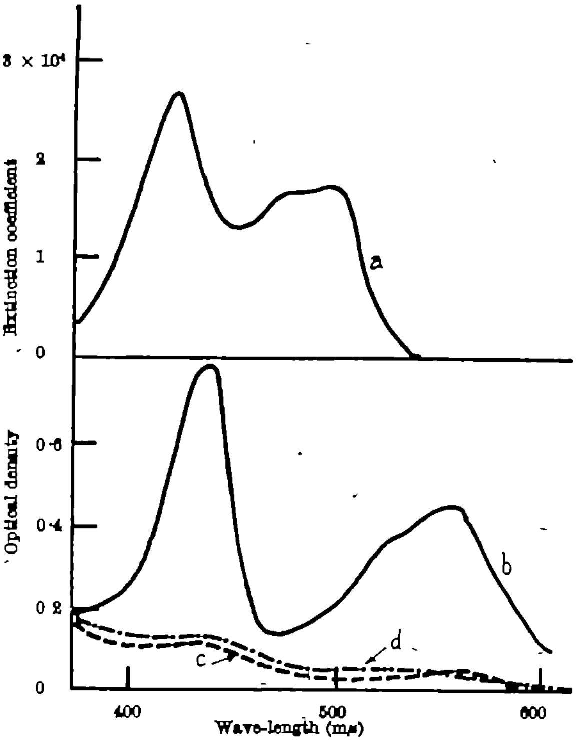


Fig. 1. *a*, Potassium ethyl 1-methoxypicrate; *b*, potassium cyanide and *s*-trinitrobenzene immediately after mixing; *c*, potassium cyanide and *s*-trinitrobenzene after 7 min. exposure to diffuse daylight; *d*, product obtained by Hantzsch and Kissel (all solutions are in acetone)

ne solid product obtained by Hantzsch and Kissel. ompound (II) may therefore have a more transient istence than has hitherto been supposed. Similar ectra are obtained in ethyl alcohol solution. This iminates the possibility that an acetone molecule involved in the complex ion, as is thought to be he case in some *m*-dinitrobenzene complexes[4].

It is interesting to note in this connexion that the pectrum of potassium ethyl 1-methoxypicrate does ot resemble the spectra of either the product of nteraction of *s*-trinitrobenzene and potassium thoxide (or methoxide) or of *s*-trinitrotoluene and otassium ethoxide (or methoxide); neither do the pectra of these two latter products closely resemble ne another. It has been suggested that in the case f *s*-trinitrotoluene + methoxide the product is an on of the type (III)[5]. The fact that the spectrum f this product has a maximum at 370 mμ which is lose to that of the picrate ion (356 mμ) may be urther evidence in support of structure (III) in this ase, as the ion (III) is *iso*-electronic with the picrate on.

# The Solid-Liquid Equilibrium Diagram of Argon and Krypton

MEASUREMENTS of the properties of condensed solutions of the inert gases should prove important in the development of the theory of solutions because of the comparatively simple nature of the interatomic forces. While, from the theoretical point of view, equilibrium diagrams are complicated in that they necessarily contain information concerning two or more forms of solution, their determination is a most useful initial step in the examination of any system.

Argon and krypton were chosen for the present investigation because they are inexpensive and because they can be condensed at liquid oxygen temperatures. The solid–liquid equilibrium diagram of this system has been previously measured by the method of thermal analysis[1]. Time/temperature curves were obtained for five different mixtures of known composition as they were heated or cooled through the transition points. The discontinuities in the slopes of these curves did not occur at a definite temperature, and the melting points and freezing points were determined by a method of extrapolation which, it was claimed, gave an accuracy in the transition temperature of 0·1 deg. The composition of the mixtures was known to approximately 0·05 per cent. These results are shown in Fig. 1, in which the mole fraction of krypton ($x$) of solutions in equilibrium is plotted against temperature.

In the present investigation this same method was tried; but it proved unsatisfactory because of the difficulty of locating the melting point for any composition and the freezing point for mixtures of about equimolar proportions. To overcome this difficulty a new method has been developed. The total vapour pressure ($P$) of mixtures of known composition has been measured as a function of temperature ($T$). Graphs of $\log P\Big/\left(\frac{1}{T}\right)$ have been drawn and although the discontinuities in slope are not 'sharp', a small extrapolation of one straight or nearly straight line enables each transition point to be determined. The results of measurements of twenty-two different mixtures are shown in Fig. 1. Temperature was measured with a copper–constantan thermocouple with an accuracy of 0·1 deg. K. and the compositions were determined to 0·5–1 per cent. Both gases were obtained commercially. The purity of the argon was such that the temperature range of melting was not more than 0·05 deg. The krypton contained 0·5 per cent xenon, which was also the case in the earlier determination[1].

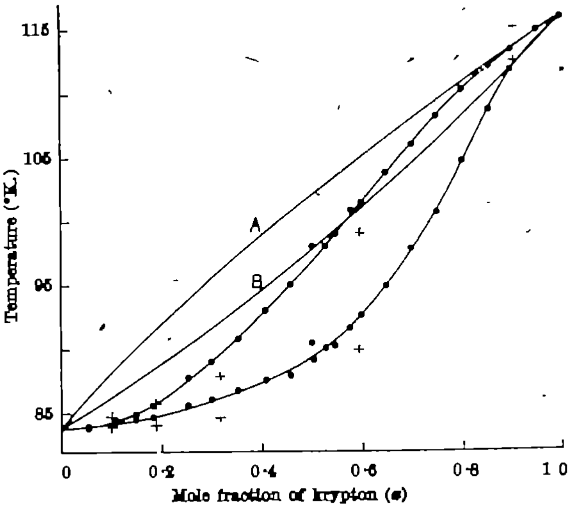

Fig. 1. Equilibrium diagram of argon and krypton: *A* and *B*, ideal solutions; +, Veith and Schröder (ref. 1); ○—○—, present investigation

Fig. 1 shows that argon and krypton are soluble in all proportions in the solid and liquid states. The equilibrium diagram that would result if both solutions were ideal is drawn on the figure. It may be seen that when $x$ approaches 1 the measured solidus and liquidus approximate to those of the ideal solutions. For all other values of $x$ the concentration of krypton in both solid and liquid solutions in equilibrium exceeds that in the ideal solutions at the same temperature. A preliminary examination of the vapour-pressure measurements indicates that, for $x \simeq \frac{1}{2}$, $\frac{P}{P_i}$ (where $P_i$ is the total vapour pressure of the ideal solution) for the solid solution at the melting point is greater than for the liquid solution at the freezing point. In both cases $P/P_i$ is greater than 1. These facts suggest that for $x \simeq \frac{1}{2}$ the deviations from ideality in the solid are more positive than in the liquid solution, and that both solutions exhibit positive deviations.

The measurements have extended down to about 62° K. for argon-rich mixtures and to 70° K. for krypton-rich mixtures, and no evidence of any phase change between these temperatures and that of the solidus has been found. If the solid solutions show positive deviations from ideality, it would be expected that at low temperatures the two substances would be insoluble. A calculation (reported in an account[2] of a meeting of the Physical Society Low Temperature Group), assuming that the intermolecular force of attraction is of the van der Waals type, shows that the separation into two phases would not occur in the temperature-range used in this investigation.

The experimental details and the results of the vapour pressure measurements will be discussed in a later publication.

I thank Prof. G. O. Jones, who suggested this investigation, for his continued help and advice.

## Serially Balanced Sequences

Williams[1] has devised experimental designs for use when several subjects are to be tested on successive occasions, and the response to the treatments on any one occasion may be modified by residual influences of the one or two previous treatments. We have recently considered the possibility of analogous designs that, under certain assumptions about the mathematical model, could be used for an experimental comparison of treatments on many occasions with one subject only. The practical importance of these designs is probably not great, but they are of interest as introducing new combinatorial problems.

Suppose that four treatments are represented by the letters $A$, $B$, $C$, $D$. Consider the sequence

$$A\,;\ B, C, A, D\,;\ A, C, B, D\,;\ C, D, B, A.$$

This is an example of a serially balanced sequence for four treatments. More generally, for $t$ treatments, a serially balanced sequence is defined as follows: (i) each treatment follows each other treatment once (hence the whole sequence has $(t^2 - t + 1)$ members, one letter being repeated $t$ times and the others $(t - 1)$ times each); (ii) after the first treatment, each block of $t$ successive treatments contains one complete replicate. The first and last treatments must be the same. From any sequence, $(t - 2)$ new ones can be generated by cyclic permutation of whole blocks of four and alteration of the first letter to the new last letter. From each of these, a further $(t - 1)$ can be generated by discarding the first letter, reversing the order of the remaining $t(t - 1)$, and inserting a new first letter. For $t = 4$, sequences can be classified into three transformation sets, all members of a set being related by block permutation, reversal and letter permutation.

Statistical analysis according to the standard additive model is practicable if the time trend can be adequately represented by $(t - 2)$ parameters for differences between the $(t - 1)$ blocks; the first treatment is regarded purely as a conditioning of the subject, and no use is made of observations on it. The immediate effects of treatments and their residuals at the time of the next treatment each require $(t - 1)$ parameters, leaving $(t - 1)(t - 3)$ degrees of freedom for the estimation of the error variance. If a longe experiment is required, so as to increase replication and to improve the estimate of error, two or mor sequences can be used consecutively provided tha all begin with the same letter: for each one afte the first, this initial letter is telescoped with the last letter of the previous sequence.

Despite the balance, non-orthogonality makes th analysis awkward. For some values of $t$ (but not for $t = 4$), additional balance can be achieved by having each block also contain one residual from each treatment. For example, with $t = 5$, the sequence

$$A\,;\ B, D, E, C, A\,;\ E, B, C, D, A\,;$$
$$C, E, D, B, A\,;\ D, C, B, E, A$$

is such that both the first $t(t - 1)$ and the last $t(t - 1)$ letters form $(t - 1)$ successive replicates.

For most experimental purposes, a more complete form of serial balance, in which every letter follows every letter including itself once, and which therefore requires a sequence of $(t^2 + 1)$ letters, is obviously preferable. However, such sequences appear to be much rarer. None exists for $t = 3, 4, 5$; for $t = 6$ there are plenty, one such being

$$A\,;\ A, B, C, D, E, F\,;\ F, C, E, A, D, B\,;$$
$$B, A, F, E, D, C\,;\ C, A, E, B, F, D\,;$$
$$D, F, A, C, B, E\,;\ E, C, F, B, D, A.$$

Cyclic permutation of blocks and reversal again generate new sequences.

Further study of these sequences is in progress, and a paper describing their application in bioassay is in preparation.

This communication was prepared without knowledge of a paper by R. M. Williams[2] in which analogous designs were discussed; Williams, however, used a less severe constraint by balancing treatments in respect of adjacent treatments on either side instead of the preceding treatment only.

## Corrosion and Meteorology

In studies of corrosion under tropical conditions, it has for a long time been the practice to quote average yearly conditions of temperature and humidity. Although laboratory or simulated tropical testing is often carried out under cyclic conditions, these cannot be truly representative of the climatic conditions unless a complete examination of the climatic conditions is first made. This is particularly important in view of the principle of critical humidity developed by Vernon, Hudson, Patterson and Hebbs, and others[1], and also the work of Clarke[2] on fluctuating humidity.

An analysis of the climatic conditions in Singapore during 1953[3] gave the following information on the percentage relative humidity per day during each month:

| Month | Hr. per day at each range of relative humidity | | |
|---|---|---|---|
| | 65–80 per cent | 80–90 per cent | More than 90 per cent |
| January | 9 | 4 | 11 |
| February | 8 | 5 | 11 |
| March | 8 | 5 | 11 |
| April | 7 | 5 | 12 |
| May | 9 | 6 | 9 |
| June | 9 | 13 | 2 |
| July | 9 | 9 | 4 |
| August | 10 | 11 | 3 |
| September | 9 | 9 | 6 |
| October | 10 | 7 | 7 |
| November | 9 | 6 | 9 |
| December | 9 | 5 | 10 |

From these figures it may be generalized that an 'average' day in Singapore has the following hours of humidity :

65–80 per cent relative humidity, 9 hr./day.
80–90 ,, ,, ,, ,, 7 ,,
More than 90 ,, ,, ,, ,, 8 ,,

These values bear a general resemblance to the average figures and ranges often quoted for Singapore : average maximum humidity, 95 per cent ; average minimum humidity, 69 per cent ; average humidity, 80 per cent. But these latter figures do not take into account the time of exposure to the maximum and minimum conditions. Time is just as important as the level of humidity in corrosion processes.

From the point of view of the deterioration of paint films on metal surfaces exposed to the direct rays of the sun, the sun temperature is of great importance, and work in Singapore has shown that sun temperatures of 130–150° F. are quite normal. A full investigation of these factors is being carried out and will be published elsewhere.

---

I should like to make two comments on Major P. A. Cartwright's letter printed above.

(1) Major Cartwright is right in stressing the important bearing of climatic conditions on atmospheric corrosion, and his view that the variation in the relative atmospheric humidity throughout the exposure period is much more important than the overall average value will meet with general approval. I am particularly interested in this aspect of the matter and have from time to time published diagrams such as Fig. 1, one of which relates to Singapore.

According to the classical researches of Vernon, the critical humidity for the atmospheric rusting of iron lies somewhere between 70 and 80 per cent relative humidity. In the diagrams I have, therefore, shown the periods of the day, averaged for each month of the year, during which the relative humidity of the atmosphere at the places concerned lies below, between, or above, these limits. We do not know whether or not the critical relative humidity varies with the atmospheric temperature ; but, if we assume a value of 70 per cent everywhere, the diagrams show that the conditions are propitious for rusting at Singapore during no less than 99 per cent of the year ; the corresponding figures for Kew and Pittsburgh are 80 and 49 per cent, respectively. Incidentally, the Pittsburgh figure and corresponding data for other American observatories suggest that on the whole the corrosion hazard due to humidity alone is rather less in the United States than in Great Britain.

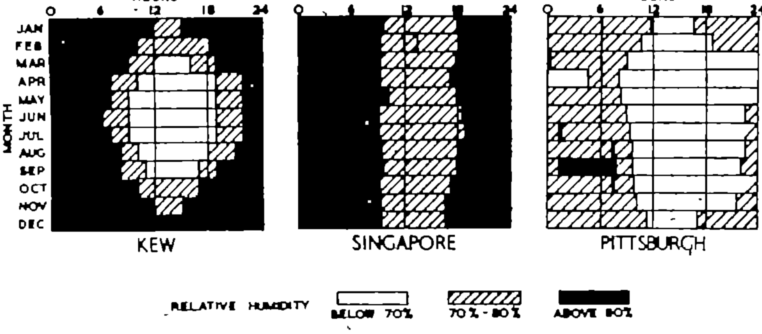

Fig. 1. Variation in the relative humidity at Kew, Singapore and Pittsburgh throughout the day

(2) It does not follow that serious corrosion will take place whenever the humidity is favourable. As Vernon showed, it is also necessary that the atmosphere should be polluted. The most damaging type of pollution is sulphur in the form of combustion products. Joint investigations by the British Iron and Steel Research Association and the Fuel Research Station have shown that in Great Britain, where the relative humidity does not vary much over the whole country, the corrosion of iron at different sites is directly proportional to the sulphur pollution of the atmosphere. Where the sulphur pollution is inappreciable, the rate of rusting is small. In conformity with this, in earlier tests made at Singapore itself, on mild steel plates freely exposed in the open at Seletar Aerodrome, the average rate of rusting observed was only 0·6 mil (0·0006 in.) per year. This figure is comparable with the rates for rural atmospheres in Great Britain—for example, 1·2 mils per year at Llanwrtyd Wells—and is much smaller than those observed in industrial atmospheres, such as Sheffield, where figures of 4 mils or more per year are not uncommon.

This does not contradict the fact that very severe corrosion may often occur in the tropics. Humid atmospheres heavily charged with salt spray, such as are found on surf beaches, are extremely corrosive, and rates of 40–50 mils per year have been recorded at sites of this type. Although the corrosion-rate falls off rapidly with increasing distance from the sea, heavy condensation may play a decisive part at inland tropical sites, since it is clear that the ease with which condensed moisture evaporates from the metal is very important. It is difficult to reproduce the full effects of this factor in small-scale experiments, and it may well be that, for practical purposes, observations made on actual articles and components will provide a better guide to the severity of the corrosive attack that is to be expected in jungles and similar places.

## Reactivity of Freshly Formed Steel Surfaces

Prince[1] has observed that a freshly sheared steel surface rusts far quicker than would be expected at ordinary temperatures. Whether or not it is always legitimate, in statistically distributed events, to draw conclusions from isolated observations, recorded facts support his statement in the present case. The corrosion probability of a freshly scraped surface is higher than that of a surface exposed to air; statistical studies by Mears[2] have shown that the probability number for rusting at scratch lines traced on iron, and, after exposure to air, covered with 0·07 *M* sodium bicarbonate, declines steadily with the duration of exposure.

Prince tentatively suggests that hydrogen peroxide plays a part in the rusting, apparently by converting ferrous to ferric hydroxide; under ordinary conditions, however, ferrous hydroxide would be oxidized by atmospheric oxygen, and there is no need to postulate hydrogen peroxide as the oxidizing agent. Incidentally, Pietsch and his colleagues[3] showed that the addition of pure (unstabilized) hydrogen peroxide to water prevented or postponed the rusting of homogeneous iron, which occurred rather quickly in water free from peroxide; possibly this passivation might not occur on steel—nor with hydrogen peroxide as found in the reagent bottle.

## An Epidemic of Words

Epidemiology is a fascinating subject. Much the same interest is aroused and the same scientific principles involved whether, with Lodge in 1603, we discuss an "epidemick [of plague] . . . common unto all people or most of them"; or with Morgan in 1728 we discover that the mange is the "epidemical distemper" of the camels of the Algerians; or we realize with Berkeley (1857) that it was an epidemic of Irish blight which sent the Irish to New York and New Holland during the 'forties of the last century; or (more metaphorically as we nowadays think) we may disagree with John Milton (1643) that divorce is a "toleration of epidemick whordom". Thus 'epidemic', soon after the word was coined, came to have a wider and a narrower meaning than the original Greek ἐπιδήμιος. Epidemiology has apparently retained this wide meaning. It is correct to discuss the epidemiology of myxomatosis in the rabbit, and when we discuss the epidemiology of Irish blight we know we are not discussing a direct attack of *Phytophthora infestans* on the unfortunate Irish, although perhaps there may have been an indirect attack on them by way of the potato murrain.

Epidemics are, of course, dangerous things. Although I could see no scientific reason for the recent re-introduction and popularization of the word 'epizootic' to discuss myxomatosis, there may have been some political reasons. I now find that I have been in error in referring to an epidemic of Irish blight, Hayes and Immer in 1942 referring to the artificial production of epiphytotics on plants. In future, epidemics on plants should be referred to, not as epiphytics (Lindley in 1830 having defined this word correctly and according to the original Greek), but as 'epiphytotics', to rhyme, one supposes with epizootics, which, of course, except for Todd's pre-emption in 1836, might have been epizoics.

This is a small epidemic of words. Epidemics are infectious diseases. Unless strong antiseptics are used we may soon find ourselves with a new science of epibiology (or should it be epibioticology ?), with the three subsciences of epidemiology, epizoology (or epizooticology ?) and epiphytology (or epiphytoticology ?). The related word 'endemic' has travelled a long way in meaning since Stanley's description in 165 of "Those endemical malignant vapours, which infect the air". Its modern scientific use was carefully defined by Charles Darwin in the first edition of "On the Origin of Species" (1859), when he wrote "in oceanic islands . . ., the proportion of endemic species (i.e. those found nowhere else in the world) is often extremely large". Cannot our epidemiologists define an epidemic to include epidemics on populations of all living organisms, whether man, potato, rabbit or bacterium ?

Since writing the above, I have found that the epidemic of words has already started, Large, in 1940, referring to the new American science of 'epiphytotiology' or the use of meteorology in the prediction of epidemics on plants.

## "Educational Problems of the Colonial Territories"

In the leading article in *Nature* of August 20 on "Educational Problems of the Colonial Territories", it is stated that "only some 450 scientists are at present engaged in Colonial research", and that "any expansion in research must draw largely on the limited supplies of scientific and technical man-power in Britain itself". Most British scientific workers are superannuated at the age of approximately sixty-five. Many of them are capable of another ten years of research, and a moderate amount of teaching. Some, at least, would be happy to work in a Colonial university or research institute. The necessary qualifications are the capacities to work in a tropical or subtropical climate, and to form friendships with non-Europeans.

Many branches of biology and geology, not to mention mathematics, require little expensive apparatus; and a salary less than that of a junior lecturer would be a welcome supplement to a pension. The research carried out would not often be of immediate economic applicability, but it would, I think, be of cultural value.

I may have over-estimated the number of suitably qualified British scientists available, but I think that the presence in a Colonial university of even two or three Fellows of the Royal Society carrying out fundamental research with African or Asian colleagues would help the local population to generate its own scientific culture.

Until it has been proved that elderly British scientists will not accept such offers, I doubt whether those interested in the intellectual development of the Colonies are justified in complaining of lack of man-power.

J. B. S. Haldane

Department of Biometry,
University College, London, W.C.1.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, October 17

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5 p.m.—Madame Alva Myrdal: "The Interplay of Factors in the Development Process". First of five Heath Clark Lectures on "The Role of Health and Education in the Process of Social Development". Further Lectures on October 18, 19, 20 and 21.)*

University College London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. F. Danielli: "Nuclear and Cytoplasmic Sites of Drug Action"*.

University of London (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Sir Charles Morris: "The Perennial Appeal of Plato". (First of nine Lectures by various speakers, on "Intellectual Currents and Their Educational Message", to be given on each Monday until December 12.)*

Institute of Metal Finishing (at the Northampton Polytechnic, St. John Street, London, E.C.1), at 6.15 p.m.—Mr F. C. Reid: "Some Experimental and Practical Aspects of Heavy Rhodium Plating".

## Tuesday, October 18

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. R. H. Garstang: "Palomar Explores the Universe".*

Physical Society (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. R. Kompfner: "Travelling Wave Tubes" (Duddell Lecture); Dr. J. W. Mitchell: Charles Vernon Boys Lecture.

Society of Chemical Industry, Chemical Engineering Group (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. C. S. de Whalley: "The Decolorization of Sugar Liquor by Solid Absorbents".

University of London (at Senate House, London, W.C.1), at 5.45 p.m.—Prof. S. W. Wooldridge: "Geography and the Physical Sciences". (First of three Lectures on "The Teaching of Geography". Further Lectures on October 19 and 20.)*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "Analogues and Equivalent Circuits".

Scientific Film Association (in the Mezzanine Cinema, Shell-Mex House, Strand, London, W.C.2), at 6.30 p.m.—Sir Arthur Elton, Bart.—Presidential Address.

## Wednesday, October 19

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. J. D. N Nabarro: "Diabetes and Carbohydrate Metabolism". (Further Lecture on November 2.)*

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 2.45 p.m.—Annual General Meeting. Presidential Address: "The Place of Astronomy in Navigation".

Institution of Post Office Electrical Engineers (in the Conference Room, 4th Floor, Waterloo Bridge House, London, S.E.1), at 5 p.m.—Discussion on "What Makes an Engineer?" opened by Mr. J. G. Straw.

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. W. A. Lewis and Mr. L. H. Watkins: "Investigation into the Accuracy of Four Types of Rainfall Recorder"; Mr. J. S. Turner: "The Salinity of Rainfall as a Function of a Drop Size"; Mr. E. M. Fournier D'Albe, Mr. A. M. A. Lateef, Mr. S. I. Rasool and Mr. I. H. Zaide: "The Cloud-Seeding Trials in the Central Punjab, June–September, 1954".*

British Coal Utilisation Research Association (in the Lecture Theatre, Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Prof. Sir Cyril Hinshelwood, F.R.S.: "The Carbon of Coal" (Fourth Coal Science Lecture).

Eugenics Society (at the Rooms of the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. F. Loutit: "Biological Hazards of Nuclear Fission".*

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.45 p.m.—Dr. James V. Neel (Michigan): "The Genetic Control of Hæmoglobin Synthesis" (Galton Lecture).*

Institute of Physics, London and Home Counties Branch (at 47 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. M. V. Wilkes: "Present Status of Digital Computors in Physical Research".

Royal Institute of Chemistry, London Section (at King's College, Strand, London, W.C.2), at 6.30 p.m.—Prof. H. C. Longuet-Higgins: "Some Recent Advances in Physical Organic Chemistry".

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. L. O. Freeman: "Particle Size Assessment".

## Thursday, October 20

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. H. Chapman: "Research as a Business Enterprise"; Mr. J. F. G. R. Haywood: "Pressure Manifestations at Great Mining Depths on the Witwatersrand".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. E. J. H. Corner, F.R.S: "Taxonomy and Tropical Plants"; Mr. A. W. Exell: "The Projected Flora Zambesiaca".

University of London (in the Metallurgy Lecture Theatre, Imperial College of Science and Technology (Royal School of Mines), London, S.W.7), at 5 p.m.—Dr. R. F. Mehl (Pittsburgh): "Diffusion". (First of four Special University Lectures on "Kinetics and Mechanisms in Metal Systems". Further Lectures on October 21, 24 and 25.)*

Physical Society, Acoustics Group (in the Physics Department of Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Mr. G. Mackworth-Young: "The Mechanics and Acoustics of Singing".

Society of Chemical Industry, Road and Building Materials Group (in the Lecture Hall of the Junior Institution of Engineers, Pepys House, 14, Rochester Row, London, S.W.1), at 6 p.m.—Dr. S. J. Gregg: "Some Observations on Dead Burning, especially of Lime and Magnesia".

Chemical Society (in the Lecture Theatre of the Institution of Civil Engineers, Great George Street, London, S.W.1), at 7.30 p.m.—Prof. M. Calvin (University of California): "The Photosynthetic Carbon Cycle" (Centenary Lecture).

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Prof. R. M. Gordon: "The Host-parasite Relationship in Filariasis" (Presidential Address).

## Friday, October 21

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. R. W. Sperry (California): "Some Neural Mechanisms Underlying Perception".*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Mr. P. L. Jones: Presidential Address.

Aslib (at the Library Association, Malet Place, London, W.C.1), at 6 p.m.—Meeting on "The Case for a New Public Technical Library and Information Service". Speaker: Dr. D. J. Urquhart.

## Saturday, October 22

Biochemical Society (in the Department of Physiology, Bedford College, Regent's Park, London, N.W.1), at 2 p.m.—Scientific Papers.

British Psychological Society, Education Section (at the Institute of Education, Malet Street, London, W.C.1), at 2.30 p.m.—Dr. K. Lovell: "A Study of the Problems of Intellectual Deterioration in Adolescents and Young Adults".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. K. C. Rosser: "A 'Hermit' Village in the Himalayas".*

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Master (with a degree or recognized teaching qualification) to teach Mathematics at the General Wingate School, Addis Ababa, Ethiopia—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting "Wingate School" (October 21).

Lecturer or Research Assistant in Bacteriology and Virus Diseases—The Registrar, The University, Sheffield (October 22).

Senior Lecturer or Lecturer in Civil Engineering and a Senior Lecturer or Lecturer in Mechanical Engineering—Registrar, The University, Manchester 13 (October 24).

Electronics Engineer or Physicist (with recognized professional qualifications in electronics, and an interest in computing machines) in the Computational Laboratory, to work on problems of character recognition in connexion with mechanical translation—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (October 29).

Assistant Lecturer in Physiology—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (October 31).

Assistant Lecturer or Lecturer in Vertebrate Zoology—The Registrar, King's College, Strand, London, W.C.2 (October 31)

Chair of Industrial Metallurgy—The Registrar, The University, Birmingham (October 31).

Lecturer or Senior Lecturer in Pure Mathematics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturers (2) or Senior Lecturers in Pure Mathematics; Lecturer in the School of Chemistry; Chair of Medicine, and a Senior Lecturer in Physiology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31)

Tutorial Student (graduate) in Biochemistry—The Registrar, King's College, Strand, London, W.C.2 (October 31).

Mycologist (with a first- or second-class honours degree) for research on freshwater fungi at Windermere Laboratory—The Director, Freshwater Biological Association, The Ferry House, Ambleside (November 1).

Research Assistant (with a degree in physics and preferably some research experience) in Physics, to undertake measurements of high precision, using a reflecting echelon interferometer—The Registrar, King's College, Newcastle-upon-Tyne (November 1).

Senior Lecturer or Lecturer in Philosophy at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 1).

Lecturer or Assistant Lecturer in Anatomy—The Registrar, The University, Manchester 13 (November 7).

Lecturer in Geography at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 7).

Lecturer (with special qualifications in inorganic or physical chemistry) in the Department of Chemistry—The Secretary, The University, Edinburgh (November 7).

Chair of Nuclear Engineering at Queen Mary College—Academic Registrar, University of London, Senate House, London, W.C.1 (November 9).

Chair of Zoology—The Registrar, University College, Singleton Park, Swansea (November 12).

Lecturer or Assistant Lecturer in Geography at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Lecturer in the Department of Education at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Senior Lecturer in Physics at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 21).

Fellow, and a Senior Research Fellow, in the Department of Statistics, Australian National University, to undertake research in mathematical statistics or its applications, including mathematical genetics—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 30).

Reader in Geology—The Registrar, University of Dacca, Ramna, Dacca, East Bengal, Pakistan (November 30).

Professor of Chemical Engineering; Professor of Soil Mechanics, and a Professor of Physics—The Dean, Faculty of Engineering, Giza, Egypt (December 1).

Guinness Research Fellow in Microbiological Biochemistry—The Administrative Officer, Department of Biochemistry, The University, South Parks Road, Oxford.

Lecturer (graduate of a British University, with industrial experience) in Power Engineering—The Clerk to the Governing Body, Battersea Polytechnic, London, S.W.11.

Physical Chemist, Scientific Officer grade (with a first- or second-class honours degree or equivalent in chemistry, and preferably with research experience in surface chemistry with special reference to wetting of solids by liquids; friction and lubrication; adhesion; capillarity; or related phenomena), at the Ministry of Supply Royal Aircraft Establishment, Farnborough, Hants, for work directed towards the solution of lubrication and fluid problems associated with aircraft—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.711/5A.

Senior Experimental Officer or Experimental Officer (preferably with a degree in physics, electrical engineering or electronics or at least H.S.C. in science subjects or equivalent qualifications) in the General Physics Division, to assist in the experimental work and maintenance of the cyclotron, and in the design, construction and maintenance of the auxiliary apparatus—The Establishment Officer, U.K. Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 2/103/410.

Senior Research Assistants (with a good honours degree in engineering, practical experience and/or research training) in the Departments of Civil and Mechanical Engineering, for work in the fields of photo-elasticity, fatigue of metals and the creep and deformation of metals at high temperatures—The Registrar, The University, Nottingham.

Technical Author (with a first- or second-class honours degree in either chemistry, engineering or physics and with appropriate experience, and preferably with knowledge of the technical aspects of atomic energy) in the Public Relations Branch, for duties which include the preparation in non-technical or semi-technical terms for general or limited publication of news items, booklets and exhibition scripts on technical and scientific subjects—United Kingdom Atomic Energy Authority, H.1B, 14 Ormond Yard, London, S.W.1.

# OPTICS AND SOUND

*by C. A. PADGHAM*
*A.R.C.S.,M.Sc.,Ph.D.,D.I.C.,F.R.A.S.,*
*Senior Lecturer in Physics, Northampton Polytechnic, London*

A new book which covers the Optics and Sound syllabuses of the Intermediate Examination in Physics, the Advanced level of the General Certificate of Education, and the final year of an Ordinary National Certificate course. It has been written with the intention of presenting Optics and Sound as interesting and vital subjects to study, rather than unavoidable examination necessities. The book is divided into two sections, eleven chapters on Optics and five on Sound. Exercises are given at the end of most chapters, with answers at the end of the book. Illustrated. 434 pages. 16s.

# INTERPRETATION OF SCIENCE

ALMOST simultaneously with the opening of the meeting of the British Association at Bristol, the September issue of *The Twentieth Century* appeared ontaining contributions from some leading scientists addressed not to the specialist but to the average, ducated non-scientist who is anxious to comprehend ome of the problems presented by scientific advance not merely in nuclear physics but also in other fields. It includes contributions from Prof. R. E. Peierls on the frontier of physics, from Prof. A. R. J. P. Ubbelohde on our increasing dependence on supplies of energy, from Prof. P. B. Medawar on the biological imperfections of man, from Sir F. Macfarlane Burnet on cell and tissue replacement in modern medicine, from Sir Frederic Bartlett on the contact of cultures and from Prof. M. Polanyi on words, conceptions and science; Mr. C. F. Hudson contributes a layman's plea for independence in the pursuit of science, and provides an excellent statement of the reason freedom for science is an interest of society as well as of he scientist. An appreciation of the implications of automation comes from Mr. Austen Albu, and the issue concludes with a discussion of science-fiction by Mr. P. Fison. The journal thus ranges over all the main fields covered in the discussions at Bristol, and he two articles in particular that discuss the formulation and communication of our ideas to one another and of our culture to other societies deal with a subject around which the main criticism of the British Association has centred in recent years.

It is in the light of this fresh discussion as to what should be the main function of the British Association and how the task of interpreting science to the community is best effected that this admirable effort of *The Twentieth Century* is appropriately considered. Clearly its success depends as much on the skilled exposition of its contributors as on the level of education and interest in the community. For that reason alone, consideration of the functions and organization of the British Association is closely related to the question of education—of the general education of the scientist himself and of the teaching of science in schools and universities generally—to which the Association devoted much attention at Bristol. The extent to which the purpose and function of the British Association require modification and the organization of its annual meeting can be improved cannot usefully be determined without regard not merely to the general climate of opinion and state of public understanding of science, but equally to the work and responsibilities of other bodies such as the universities, the learned societies and the professional nstitutions. The shortcomings of any or all of these bodies should not be visited solely on the British Association.

The discussion as to what the British Association ould do to increase the public understanding of cience and how it should do so seems inclined to lose ight of this, and one welcome feature of Mr. Ritchie Calder's presidential address to the Assembly of Corresponding Societies was that, in pressing for a renewed attempt to overcome the fragmentation of science, he indicated that other bodies besides the British Association have responsibilities here. This special number of *The Twentieth Century* is likewise a reminder that the Press itself has certain responsibilities, and also suggests that those responsibilities are by no means as narrowly limited by the shortcomings of scientists themselves as Mr. Calder suggested. Whatever criticism may be levelled against the exposition of particular contributions to this symposium, they do not support his charge that scientists by and large are illiterate, inarticulate and irresponsible. On the contrary, they demonstrate that, as he admitted, some scientists are at pains to be comprehensible, to be explanatory and to recognize their responsibilities.

One dominant impression, indeed, left not only by the British Association meeting but equally by the conferences on the application of nuclear energy and by other recent events, is the extent to which scientists are recognizing these responsibilities. Further, whatever criticism is made of particular proceedings at the Bristol meeting, a second impression left by that meeting is that scientists are no less concerned about this problem of fragmentation and communication, and are determined both to improve their own capacity to communicate their ideas and also the means by which the community is informed of what they are doing and how and why they are doing it. The situation is not entirely the fault of the scientists themselves, for all the truth that there is in much of Mr. Calder's criticism: it is equally a failure of our educational system and our newspapers and broadcasting system—they have their own share of responsibility for the ignorance on the part of the average person of the nature of science and its limitations, as well as its potentialities for human welfare if used wisely.

These factors must be borne in mind in considering what scientists themselves can do to repair the situation and how far any one institution like the British Association can itself correct the fragmentation of science by organizing its annual meeting so as to provide an effective scientific stocktaking and encourage the re-definition of the frontiers of knowledge in each specialized field, relating one to the others and providing scientist and layman alike with a clearer sense of perspective. Those possibilities would, of course, be improved by educational reform, both in the training of the scientist and in the training of the ordinary citizen, just as they would be assisted by more adequate press reporting, as well as possibly by symposia such as *The Twentieth Century* has published.

Leaving educational reform on one side, disregarding the Press, save to observe that the newsprint situation is at least partly responsible for the poor reports that the British Association meetings receive to-day, compared with twenty years ago, and limiting our attention to action which scientists themselves might initiate to meet Mr. Calder's criticisms, it is only fair to point out that the Bristol meeting itself produced examples of a new outlook, and a readiness to consider what new methods and practices could be brought to assist the interpretation of science across disciplinary frontiers in an age of broadcasting and television. Scientific films, for example, are clearly coming into their own, and a new attitude towards the reading of papers indicates something much more fundamental than an attempt to raise the general standard of presentation and delivery. Besides the self-denial which will be demanded if the number of papers is to be brought down to a figure more in keeping with the supply of first-rate expositors, the president of the Physics Section, Prof. N. F. Mott, has indicated that the aim in his Section is to deal with subjects at about 'Third Programme' level. There were some notable examples of lucid description of advanced scientific work and of taking printed papers as read so that the whole of the allotted time could be given to a discussion.

Such practices, it should be remembered, may involve a break with the tradition of learned societies generally and not specifically of scientists, and it must also be recognized that changes in technique of this order require a good deal of creative and constructive thought and experiment before they can be adopted as standard practice by scholarly bodies. It is encouraging to find evidence that this is proceeding—and probably a good deal faster than some external critics realize or allow. Apart from this, the steadily growing practice for the various sections of the British Association to arrange joint sessions at which topics of common interest are discussed not merely across disciplinary frontiers but also at a level well within the level of a determined layman, shows that the Association is already attempting to deal with this problem of fragmentation. It can no longer be said without some qualification that the Association's programme consists entirely of unrelated papers or unco-ordinated themes: some specialists at least are dealing with their subjects in terms comprehensible to specialists in other fields or to an educated layman.

If we are to correct the fragmentation of science and solve this problem of exposition, the key-word is 'education'. The scientist may have far to go to remove entirely the reproach of ineffective exposition, but the limits of exposition are ultimately set by the standard of education of his public. The problem will not be solved merely by removal of the scientist's own inhibition about exposition or interpretation to a non-specialist, by improving his capacity to express himself clearly and concisely to those working outside his own field or by ensuring that his general education makes him aware of the human and cultural elements in the world in which he is working. It depends equally, as Mr. J. F. Wolfenden and Dr. J. Bronowski insisted so emphatically at Bristol, on our making sure that the education of the ordinary citizen is such that he can understand what the scientist says to him.

That point is fundamental in considering, for example, such object lessons as the Lunar Society cited by Mr. Calder. It was the absence of any gulf in education and terminology between the scient and the layman, quite as much as the mark amateur element among the scientists of the tim that facilitated the exchange of ideas and free flow discussion between the scientist, amateur or pr fessional, and the industrialist and practical man affairs in that body. The contribution to the develo ment of physical science and of industrial chemistr for example, which flowed during the latter part the eighteenth and the first half of the nineteen centuries from the meetings of the Lunar Societ the Manchester or the Newcastle Literary a Philosophical Society or the Whalley meetin started by Dr. Lyon Playfair, is only now becomi appreciated, and perhaps its full extent remains yet be demonstrated.

What Mr. Calder did well to remind the Assembl of Corresponding Societies, which is perhaps pa ticularly suited to deal with some aspects of adu education, was the danger of allowing the spirit universal inquiry to be choked by the growth barriers, not simply between the humanities a science but also between the sciences themselve which hinder or prohibit discussion except withi narrow fields. Semantics is indeed a large factor the fragmentation of science, and scientists themselves must take this question of language muc more seriously if the fragmentation of science is be checked and overcome; without some commo understanding, if it is too much to say that a scienti does not know what he is doing, it is certainly tru that he is wasting his time. Clarity and accuracy explaining and describing his results are as an essenti and intrinsic a part of his work as precision in makin and recording his experimental observations rigorous reasoning in drawing his conclusions.

Mr. Calder's clear statement of the dangers of th present situation deserves to be pondered by layma and scientist alike. Much that he said had been sai before on different occasions and in different wa by scientists to scientists; for the danger, f example, of an unhealthy and mistrustful popul attitude to science has been realized by man scientists in Great Britain as well as in the Unite States since the Oppenheimer case last year. S too, the shortcomings of the educational system Great Britain which he noted are generally reco nized in current discussions of higher technologic education, of university education, and of general further education; though not perhaps as yet wit the sense of urgency necessary to make fundament changes. Mr. Calder, for example, directed attentio to suggestions made more than ten years ago in th report of the British Association Committee on Post War University Education which have never bee implemented.

One at least of the joint discussions at Bristol di something to stimulate the re-examination of th and other proposals for facilitating the study natural science on lines wider than those of any the specialized science schools; and there is som reason for hoping that in ways such as this th British Association may steadily grow more influenti in stimulating the changes needed in the education system and practice of Britain. So, too, the closer planning of its annual meeting could contribute to the more effective interpretation to the general public nd to the specialist in other fields of scientific advances, as well as to inter-disciplinary discussions. uch planning and reorganization of the Association's rogramme demands, however, in the first place a clear conception of the functions and work of the Association in the world to-day. It demands no less clear ideas as to the part which the learned societies and professional institutions have to play in inter-isciplinary discussion, and in the education of the public as to the significance of particular scientific advances or the importance of the scientific and technical factors in matters of public concern. Equally it calls for the support and full co-operation of such bodies.

Full account must be taken of all such potentialities in order that waste of effort may be avoided and the best use made of our limited resources, just as the fullest possible use should be made of all supplementary methods of educating the public mind, whether through the Press, the cinema, broadcasting and television or the public library service. We need to remember, in fact, as the Library Association was old at its recent annual conference, that the public library is the major instrument of adult education, and especially of the informal education which is an essential element in the production of a complete and well-rounded human being. It was a director of education who remarked in the Association's annual ecture: "When I am most uncertain about the virtues which education is intended to promote, and about the methods by which we try to promote them, find comfort in thinking that the money we spend on public libraries, with its result of putting books into the hands of millions of people who would otherwise not read them at all, is the only expenditure of which we can say with tolerable certainty, 'This causes education to happen' ".

That these implications are being discussed is perhaps the most hopeful sign that the dichotomy and rivalry of science and the humanities, and the fragmentation of science itself may be ending. The scientist who has come to recognize his responsibility for seeing that, so far as possible, the ordinary educated man and woman understand the social and political implications of new scientific knowledge, has taken one step towards recognizing his responsibilities as a citizen. Nor is he likely to be backward n realizing the dangers to science itself if there is nsufficient understanding of the nature of scientific work on the part of the nation as a whole, or of that small part of it which holds political power.

It is not simply that, as Dr. Eric James remarked n his lecture to the Science Masters' Association on 'Science and Citizenship", the intellectual resources of government will be gravely impoverished unless many of those now being trained in the sciences rise to positions in administration hitherto held by arts men: there is also grave danger that insufficient resources will be placed at the disposal of science and scientists. Moreover, if, as Dr. James suggests, we reach a stage in which the possible supplies of ability are insufficient for the technical needs of Britain, there is real danger, not so much that too high a proportion of the national intelligence is directed into scientific channels—though this, too, is serious—as that at some stage the limitation of human capacity will force us to select objectives for study and pursuit, and we may choose wrongly.

This is the real danger to intellectual freedom and scientific advance, and it will clearly be greater unless men of science are prepared to use their gifts and training in administration and government and not simply in research. We need more and more, in public debate, men of science, aware indeed of the limitations of their method and technique, but none the less alert and competent to detect nonsense when it is presented in public affairs no matter what support it receives from interested groups or political caucuses.

Lastly, if scientists themselves are to undertake these responsibilities of public education and to repair the fragmentation of science and its division from man's wider cultural heritage, we must remember, as Dr. James pointed out, that a major responsibility rests on those who train them to see that the education they receive fits them to be citizens and statesmen. To produce such men, understanding the dangers and opportunities that are provided by the discoveries they themselves are making, is a task to be undertaken urgently and with determination. It means infusing into the education of such men and women the essence of the older studies, so that they are, as Dr. James said, "prepared and equipped to lead mankind to resist the temptations of purely material triumphs, and to use science not as a means of enslavement but as a force for the liberation and enrichment of mankind".

---

## BIOLOGY OF TSETSE FLIES

### The Natural History of Tsetse Flies

An Account of the Biology of the Genus *Glossina* (Diptera). By Prof. Patrick A. Buxton. (London School of Hygiene and Tropical Medicine Memoir No. 10.) Pp. xx+816+47 plates. (London: H. K. Lewis and Co., Ltd., 1955.) 84*s*. net.

FOR more than fifty years, the various species of tsetse fly have been studied from many aspects by entomologists, medical men and veterinarians, and as a result an immense amount of information has been collected and published. This has produced a considerable literature of varying quality, which has not been reviewed in its entirety for a very long time. The bulk of the field-studies have been by British scientists working either on the eastern or western sides of Africa, and frequently under very different conditions. Arising from the researches of these two schools of tsetse ecology are two separate masses of literature with frequently only the most tenuous of links. At last, in the person of Prof. P. A. Buxton, a builder has appeared who has bridged the gap with a firm structure, containing no doubtful planks.

Within the compass of this superbly produced volume the author has included the most important basic facts on the anatomy, systematics, distribution, metabolism, reproduction and ecology of tsetse and their relation to disease. It must not be thought that this is one of those dull encyclopædic volumes—a lumber room of facts reserved for use by the specialist. On the contrary, it is an extremely interesting book about an extremely interesting genus of insects.

Anyone who has studied the tsetse problem appreciates what fascinating fields are open to the research worker. He may legitimately study the insect in relation to climate, vegetation and game, or he may study the habits of man and cattle in relation to the fly; or if he prefers a more restricted field, he can investigate the ecology of the trypanosome within the tsetse fly. The results from these various lines of research are likely, when integrated, to aid in the discovery of improved methods of destroying the insect vector, of preventing contact between the vector and man and his animals, and of discovering the trypanosome's requirements if it is to be carried by the tsetse to new mammalian hosts.

The fascination of the subject has been well brought out by Prof. Buxton, who has avoided the dreariness produced by dealing with each species separately and has, instead, divided his subject into topics such as source of food, movement and rest, tsetse and trypanosomes; such an arrangement enables the reader to obtain an excellent picture of the habits of the tsetse fly and the problem it presents to man in tropical Africa.

Since the War, there has been a very considerable expansion in the numbers of scientists engaged in research on tsetse flies and trypanosomiasis; a new generation of such workers has come into being. The pre-war literature on the subject is scattered through many different journals, and is often inaccessible to those who are not working in one of the few central laboratories; the unavoidable result has been that some old discoveries have been re-discovered and published anew. The appearance of this book is therefore most timely, for not only does it serve as a literary bridge across the two sides of the continent, but also as a bridge between the pre-war and post-war generations of workers.

Prof. Buxton has not been content just to pick out the information from the summaries of all those papers that were appropriate to his topic; in cases where the paper appealed to his selective instinct he has incorporated digests of the actual experiments, as well as the original diagrams, or versions of the original which have been re-drawn by his colleague, H. S. Leeson, who has also contributed many original maps, and text-figures. It is this treatment of the subject which has made the book so readable. Caution should be exercised when reading the distribution maps, remembering that these are on a very small scale. For example, from Fig. 29 one would get the impression that *G. medicorum* extended along the littoral and was a denizen of the tropical forest belt; in reality its distribution lies along the northern side of this belt in the country which is transitional between forest and savannah, and only approaches the coast in one or two dry areas.

In addition to 165 text-figures, there is an excellent selection of photographs of a very high standard. Many of these illustrate the different types of vegetation favoured by the different species of *Glossina*, and special features in tsetse ecology, such as the feeding grounds, breeding sites and resting haunts. There are also some good photographs illustrating the value of aerial survey for studying the vegetation types, and detecting the presence of the plant associations most favoured by the fly. Such plates add enormously to the value of the book, as a mer list of botanical species can convey little to th reader who is unacquainted with them and the typ of vegetation which they produce.

The ten appendixes at the end of the book are o particular value to the research worker, as the provide detailed descriptions of techniques whic should lead to a standardization of the methods used the subjects range from methods relating to metabolism, techniques employed in demonstrating trypanosomes in tsetse, to the conventions used in mapping the species distribution.

The author has taken the end of 1952 as his deadline, and it can safely be said that he has omitted references to little of real value that has been done prior to that date; the book is therefore of grea value to all who are working on the tsetse problem. It is also of special interest to those working on methods of field-survey and estimates of insec populations, as the tsetse may be considered as a classical organism in this respect, much original work having been done on this aspect by the late Dr C. H. N. Jackson and others. Further, the book is o general biological interest since it brings out mos clearly the intriguing relationships that exist between the tsetse, climate, vegetation and man, his animals and the wild game; it also demonstrates how an improved understanding of these relationships has frequently revealed some key factor alterable by man which has enabled him to change the environment and so control the insect. For example, it has been found that large areas of woodland can sometimes be freed of tsetse by the removal of only certain essential types of vegetation; similarly, under certain conditions riverine tsetse can be eradicated by discriminative clearing of the vegetation, which in this case destroys an essential ecoclimate.

Prof. Buxton is to be congratulated on the production of this magnificent volume, which will be the standard work on the subject for many years.

T. A. M. Nash

# TREATISE ON ZOOLOGY

## Traité de Zoologie

Anatomie, Systématique, Biologie. Publié sous la direction de M. Pierre-P. Grassé. Tome 12: Vertébrés: Embryologie—Grands Problèmes d'Anatomie Comparée—Caractéristiques Biochimiques. Par P. Brien, R. Cordier, A. Dalcq, Ch. Devillers, M. Florkin, P. Gérard, L. Lison, R. Matthey, J. Pasteels, J. Piveteau, A. Rochon-Duvigneaud et F. Stéphan. Pp. viii+1146. (Paris: Masson et Cie., 1954.) Broché 9,800 francs; Cartonné 10,550 francs.

This volume, Tome 12 of the whole work, is the seventh of the now well-known "Traité de Zoologie" to appear (two of them are each composed of two fascicles the size of volumes). It is introductory to the study of the vertebrates and deals in a general way with the embryology, development, adult structure of the group and the various fundamental problems that arise from a consideration of its comparative anatomy. It immediately calls to mind the classical "Studies on the Structure and Development of the Vertebrates" by the late Prof. E. S. Goodrich, since many topics are common to both. It differs in that Prof. Goodrich said of his work, "It is not a complete treatise, but deals with certain subjects and problems of special interest", hereas the "Traité" attempts to cover the whole eld and has in addition a short but interesting chapr on the biochemical characteristics of vertebrates. he twenty-four years separating the two works ave been fruitful ones. The contents of the present olume are difficult to appraise because it is to be llowed by others treating of the separate classes; hat on birds has already appeared, and so what ppear to be gaps may only be postponements. Thus, 1 the excellent account of the eye, the portion ealing with birds only mentions the pecten ncidentally and very briefly, but it is adequately lealt with in the bird volume.

Perhaps too much stress has been laid on the old lassics even for a general introduction; for example, he figure of the arterial system of the salamander is aken from Bethke (1898) with no mention of the nore detailed and modern work of Francis (1934). nformation on the elasmobranchs is taken from ?arker, and the much more recent and comparative vork of Daniel and his school not considered. On he whole, the chapters dealing with the central ervous system, eye, ear, olfactory organ and teeth ppear to be the most outstanding: the last four re dealt with by members of the medical faculty out none the less in a completely comparative manner both anatomically and functionally. No ther text-book of zoology contains such a wealth of nformation on these important subjects. They are lso up to date and, in one case, include information published in the previous year, which is praiseworthy n such a large work.

The whole format of the volume, its paper, press work and illustrations carry on the very high standard of the previous volumes. The 733 text-figures, line block (467), line block with colour (23), half-tone drawings (157), half-tone photographs (47) and half-tones of macro and micro sections vary considerably in usefulness and presentability. The line-blocks Figs. 5, 6, 7, 234 and 633 are excellent, as are those with colour—for example, Fig. 44, which occupies three whole pages, and Fig. 46 on four pages—and they show the wide range of effects that can be produced by this process. In the chapter on the central nervous system considerable use has been made of photographs of actual dissections, and they are not an unqualified success. Some—for example, on pp. 239, 252, 259, etc.—are not very helpful; others with an explanatory diagram are more easily comprehended. It is not obvious why good drawings were not used throughout, since readers of this work will be familiar with the appearance of dissections, usually difficult to photograph. It is quite otherwise with the photographs of the macro and micro sections, many of which are quite as clear as a diagram, and they do represent the actual object. It is a pity that the nomenclature has not been unified and brought up to date; for example, the same animal appears as *Scyllium* and *Scylliorhinus*, and another as *Hatteria* and *Sphenodon*. Moreover, each of the pair is indexed separately without any cross-reference. It is not as if the original name had been retained, for on p. 717 *Scylliorhinus* is used in reproducing a diagram from Goodrich, who called it *Scyllium*.

In spite of these blemishes, the volume is most useful and to be highly commended. It deals with a number of topics in an up-to-date and adequate manner and is a welcome addition to the few general works on vertebrates. Doubtless it will hold its place as an important work of reference for a considerable time. C. H. O'Donoghue

# EDUCATION AND SOCIAL DEVELOPMENT IN THE COLONIES

**Education and Social Change in Tropical Areas**
By Prof. Margaret Read. Pp. ix+130. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1955.) 8s. 6d. net.

The papers collected in this volume were written over a period of nearly ten years and addressed to audiences as diverse as the subjects covered. Most of them were presented, however, during the years 1950–52, and although the common theme—the application of social anthropology to educational problems—gives the book more unity than its structure would possess, it nevertheless lacks the coherence and incisiveness that it might have had if Prof. Margaret Read had sat down to rewrite the papers and weld them into a systematic discussion of a few leading themes. As it is, too many points are raised and cursorily dismissed, problems are indicated rather than analysed, and though there is less repetition than might have been expected, the net result is less satisfactory and penetrating than some of the individual papers.

None the less, the book is to be welcomed not solely as a contribution to the clearer understanding of the fundamental conditions in which Colonial development and welfare operate. Dr. Read indicates clearly and forcefully the leading questions which have to be considered in formulating educational policy, or social policy in general, in the Colonial and similar territories: the problem of communication and the importance of studying the results of cultural contact and education in terms of the changing patterns of living and social grouping among the people of the tropical areas. But when she also depicts in so stimulating a manner the difficulties that arise—because what is educationally desirable may be socially unacceptable, or because what is socially desirable is economically unattractive, or because the economically attractive is politically impracticable—we are aware that much that is written of tropical areas has its bearing on educational policy in Great Britain.

Quite apart from its contribution to the understanding of Colonial welfare and development, Prof. Read's book is of real value for its bearing on education in Britain on two counts. First, it emphasizes the need for a similar approach to our own educational problems; it raises, for example, such leading questions as the appropriateness of our educational system to the society in which we live. Secondly, it demonstrates the value and importance of the holistic approach to educational problems, whether, for example, at the upper end in considering the expansion of higher technological education and the balance between that and university education, on one hand, and technical education, on the other; or, at the other end of the speculum, in considering the place of adult education and whether it is not desirable that some attempt should be made by such means to reshape particular group attitudes to higher education.

The book is admirably produced and reasonably priced, but once again it has to be recorded that the absence of both index and references detracts from its full value in stimulating further thought and study on problems which determine the future of Britain as much as that of her tropical dependencies.

R. Brightman

# A HUNDRED YEARS OF TECHNOLOGICAL TRAINING AND RESEARCH IN SWITZERLAND

By Prof. MAX WILDI

Swiss Federal Institute of Technology

THE twenties and thirties of this century witnessed the centennial celebrations of the earliest non-denominational university institutions, of the type of University College, London. Now, in the middle of the century, a later phase of nineteenth-century development in the domain of higher education has completed its first century: the specialized technological colleges and institutes. Thus during October 20–22, the well-known Eidgenössische Technische Hochschule of Zurich (the Swiss Federal Institute of Technology) is entertaining guests of honour from all over the industrialized world to celebrate its first centenary.

The official opening of the first courses of this school in October 1855 was preceded by half a century of idealistic projects and enthusiastic promotion by a few far-sighted men, by petty regional squabbling and rivalry, long parliamentary debates ending in what, to the first promoters, would probably have appeared a sadly truncated affair, but which has proved a wise and far-sighted solution, eminently wise in what was not attempted and equally far-sighted in what was actually done. The first promoters, men like Stapfer, Switzerland's ambassador to the First Consul in Paris, had conceived the lofty idea of a central, national university embracing all faculties plus a technological section, to be supported and administered by the central government. In a country of such cultural, religious and linguistic diversity as Switzerland, the plan, had it ever been put into practice, would have led either to a pitiably atrophied, characterless shadow of a university, or to an aggressive stronghold of centralization in a sphere where, according to Swiss political tradition, the cantons, as embodying the regional autochthonous forces, are absolutely sovereign. It was different with the new technical sciences, for example, mechanical and electrical engineering, chemistry, geodesy and geology. These were, to a very large extent, of foreign, partly British, growth. They had no connexion whatever with the historical and regional forces. None of the older Swiss universities (Basle and Geneva) or even their younger liberal sister institutions at Zurich or Berne had seriously started teaching technology or science. Thus the way was open for a central school of engineering and kindred subjects.

The Swiss Federal Institute of Technology owes its initial impulse, its generous endowment and the wide and lofty conception of its aims to the great liberal revolution of 1848. That year marks the victory, in Swiss history, of the urbanized Protestant areas with their old textile and watchmaking industries over the mainly agricultural Roman Catholic mountain valleys, among which lay the cradle of Switzerland. Zurich, the rising industrial town, terminus of the first railway and centre of important engineering plants, was chosen as the seat of the new school. It was here, on the site of the old ramparts overlooking the Limmat, that the imposing main building in classic style of the Institute arose to the design of Gottfried Semper, the first head of the school's architectural section. Originally, that is, in the half-century between its erection in 1864 and the completion of the neighbouring university buildings, it housed both the Federal Polytechnic School as it was then called after its famous prototype, the École polytechnique of Paris, and the cantonal University.

The remarkable development of the technical sciences in the course of a century is reflected in the rapid growth of this representative centre of technical study and research. Its original six sections comprising architecture, engineering (two sections), chemistry, forestry and general subjects, had to be doubled by subdivision and the inclusion of natural science, theoretical mathematics and physics, pharmaceutics, surveying and military science. The development of the Institute during recent decades from a mainly educational centre to a scientific research institution made it imperative to adapt the existing laboratories to their new purposes and to add many new ones. Among more recent additions may be mentioned institutes or laboratories for photogrammetry, geophysics, micropalæontology and applied mathematics. In the course of the past seven years alone, twelve new professorial chairs for these and other subjects have been created. The staff of the Institute comprises at present 107 professors, 68 *Privatdozenten* (assistant professors and lecturers) and 237 assistants. Professors have the same standing as holders of full university professorships. The number of full-time students varies from 2,600 to 4,000. Of these, 15–25 per cent are foreigners. Their studies cover, as a rule, a four-year course ending in a final diploma examination. A minority of approximately 25 per cent of all postgraduates go in for independent research in order to obtain the degree of a doctor of technical, mathematical or natural sciences. Many well-known scientists and leading engineers received their early training at the "ETH"; among others, Röntgen, Sir Alfred Mond, Stodola and Einstein. The latter two were members of the Institute's teaching staff as well.

One special feature of the Swiss Federal Institute of Technology has attracted the attention of educational authorities in countries where new technological colleges were being planned or actually founded, as, for example, Australia: it is the existence, side by side with the specialized sections, of a large, fully equipped general section dealing with such humanistic and non-technical subjects as philosophy, psychology, German, French, Italian and English language and literature, political and constitutional history, law and economics, art history and history of music. Most of these formed part of the original programme of 1855. From the fact that English as the only non-national language was given a half-time professorship at the newly founded school, one may gather how great was the prestige Britain enjoyed as the foremost liberal and industrial power. (The chair for English has since been made a full-time professorship.) All courses in this so-called free section are voluntary, students being only required to attend at least one hour a week in any of the various general subjects. The Institute is proud to have had among the professors of this section men like Jakob Burckhardt, Friedrich Theodor Vischer, Francesco de Sanctis and, in recent times, Carl Gustav Jung.

In the first century of its existence the Swiss Federal Institute of Technology has played a very important national and a surprisingly large international part. It has provided Switzerland with generations of first-class engineers who helped to open the magnificent but barren mountain fastnesses to international traffic by boring the Gotthard and Simplon tunnels and by harnessing the Alpine torrents to provide the country with electric energy. It has trained thousand of architects and chemists, and it has equipped the schools of Switzerland (and itself) with young teachers in mathematics, physics and natural science, who in their turn provided an élite of scholars. The latter was supplemented by eminent foreign talent, which was freely admitted and even sought after. For many generations the eastern European and Balkan countries not only sent thousands of students to Zurich, but they also gave the Swiss Federal Institute of Technology some of its brilliant scholars, men like Stodola and Ruzicka.

In a country like Switzerland, a country that is so poor in natural resources that three-quarters of its energy supply and nearly all its raw materials as well as a very large amount of foodstuffs have to be imported from abroad, a population of five millions can only be maintained at the present high standard of living if all the latent energy of the nation can be called forth and given an opportunity of profitable activity. For Switzerland this means specialized activity in the sphere of international trade and industry rendering high visible and invisible exports. It need scarcely be said that, in such an economy, the leading centre of scientific and industrial research and training holds and will continue to hold something like an intellectual key position.

---

# ADVANCES IN ORGANIC CHEMISTRY

## FOURTEENTH INTERNATIONAL CONGRESS OF PURE AND APPLIED CHEMISTRY

THE Fourteenth International Congress of Pure and Applied Chemistry took place in Zurich during July 21–27. It was devoted to organic chemistry and was undoubtedly the most representative gathering of organic chemists held in recent years.

Here, on the favourite meeting ground for international conferences, refreshed by the beauty of the city and its surroundings, delighted by the generous hospitality of their hosts, and encouraged by the messages of peace and political *rapprochement* emanating from Geneva, more than three thousand chemists and their ladies from nearly forty countries were assembled. The distinguished company included many leaders of the science, and the list of participants might well have been taken for the author index of a text-book of contemporary organic chemistry, with scarcely an important name omitted.

The scientific programme was arranged in three main sections, covering (i) theoretical and physical organic chemistry, (ii) natural products, and (iii) synthetic, industrial and analytical organic chemistry. It comprised fourteen lectures, delivered by invited speakers, and more than six hundred papers read in ten groups meeting simultaneously. To this were added visits to the chemical industries in Basle and to various other factories, numerous excursions and social events, including a reception at the Stadthaus and a banquet attended by more than a thousand people, as well as the committee meetings of the International Union of Pure and Applied Chemistry, which was simultaneously holding its Eighteenth Conference. Thus, the time-table was a rather crowded one, and no praise can be too high for the superb work done by the organizing committee, presided over by Prof. Paul Karrer, and for the unobtrusive efficiency with which its arrangements were put into effect.

It is, of course, quite impossible within the space of a short article to attempt even a summary of the scientific material presented at the Congress. In any event, no one Congress member could be physically present at more than about one-tenth of the proceedings. Fortunately, complete abstracts of the papers (usually with references to the journals in which they are to appear) are available in the Congress handbook, a handsomely printed volume of some 440 pages, while the lectures will be published *in extenso* before the end of the year as a special supplement to *Experientia*. Rather than to catalogue a long list of titles, better purpose might be served, therefore, by mentioning a few of what appeared to be particularly significant or memorable contributions (though such a selection must necessarily be a very personal one) and setting down some general impressions and reflexions.

Perhaps the most noteworthy feature of the programme was the emergence of physical and theoretical organic chemistry as a fully-grown branch of the subject, equal in importance and scope to the other two major branches. The papers read at the Congress were numerically divided in almost equal proportions between the three sections, and five of the fourteen lectures were devoted to a physical organic topic. C. Dufraisse discussed photoxidation, with particular reference to transannular peroxides formed by polycyclic aromatic compounds. C. K. Ingold reviewed the contributions of his school to the theory of steric hindrance. N. A. Nesmeyanov outlined a descriptive theory of conjugated systems which seeks to interpret their twin or multiple modes of reaction without recourse to the concepts of resonance or mesomerism. Recent developments in our knowledge of carbonium-ion intermediates were described by S. Winstein, who reported that the acetolysis of the anti-7-norbornenyl tosylate (I) proceeds with a rate greater by a factor of $10^{11}$ than the saturated derivative (III) owing to the intervention of the bridged ion (II). Another remarkable example of transannular interaction occurs in the acetolysis of the benzoate (IV), which yields a hydrocarbon possessing the architecturally satisfying structure (V), besides other products.

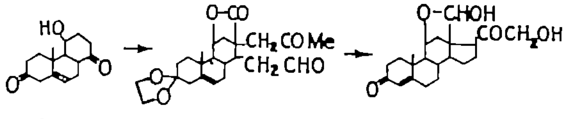
IV V

D. H. R. Barton reviewed the principles of conformational analysis, which have so revolutionized our understanding of the chemistry of alicyclic compounds. Using these principles, the conformations of molecules containing several fused *cyclo*hexane rings can usually be deduced from qualitative data; but work in this field is now moving towards still subtler and more quantitative aspects of stereochemistry. Studies on reaction-rates, such as of the formation of benzylidene derivates from triterpenoid ketones, reveal that even widely separated groups often show marked interactions, and Prof. Barton suggested that distortion due to unsaturated substituents can be transmitted through a large molecule by small contiguous alterations in valency angles and atomic co-ordinates. He coined the term ‘conformational transmission’ to describe this novel effect.

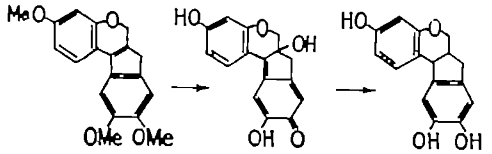
Numerous papers of great interest were read in this section, so that it would be inappropriate to single out any individual contribution for specific mention. The main lines to be followed in interpreting quantitatively the basic facts of organic chemistry now seem to be firmly laid down, and it appears that pioneering investigations will be increasingly concerned with what may be termed non-classical phenomena. It also seems quite safe to forecast a continuance of the notable activity in the field of photochemical and radiochemical organic reactions and in the application of spectroscopic and isotopic tracer methods.

In the section of natural products, many outstanding feats of synthesis were described. V. du Vigneaud outlined his recent work culminating in the complete solution of the structure of oxytocin, the principal labour-inducing and milk-ejecting hormone of the posterior pituitary gland. R. B. Woodward described the total synthesis of strychnine, an achievement which but a few years ago still seemed altogether outside the range of the attainable. Two remarkable syntheses, not previously published, were announced from Swiss industrial research laboratories. Aldosterone (VIII), the most potent hormone of the adrenal cortex, which was isolated and had its constitution determined only last year by a team led by T. Reichstein, has been synthesized through a sequence of about twenty steps starting from Sarett's tricyclic ketone (VI) through the intermediate (VII) (A. Wettstein and co-workers, Ciba Company). A highly efficient synthesis, starting from β-ionone, of β-carotene, one of the most widely distributed carotenoid plant pi ments, has been worked out and is already bein employed for commercial production on the tremendous scale of several tons per year (O. Isler an co-workers, Hoffman - La Roche Co.). The nov key-step in the synthesis is a chain-lengthening c unsaturated aldehydes by the condensation of th corresponding acetals with vinyl or propenyl ethe In addition to β-carotene, lycopene and no less tha six other carotenoid hydrocarbons have been obtaine by similar routes, and the first total syntheses of th oxygenated carotenoids, zeaxanthin and physalien have been achieved. The carotenoids are natura and harmless colouring matters for margarine an other food products, and their manufacture will n doubt rapidly bring to an end the use of aniline dye for this purpose.



VI VII VIII

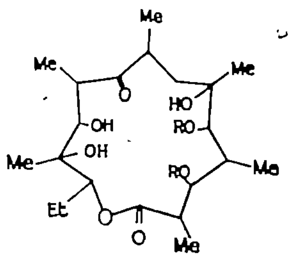
In a paper which will be remembered as much fo its historical associations as for its scientific interest Sir Robert Robinson described the final stages in th synthesis of brazilin (XI). Sir Robert recalled tha he began his studies in this field—almost his firs research topic—nearly fifty years ago with Prof W. H. Perkin, jun., at Manchester. Deoxytrimethyl brazilone (IX), which had previously been synthesized, was converted through a series of steps int *dl*-brazilein (X). Borohydride reduction, followed b resolution of the menthyloxyacetyl derivative, the gave *d*-brazilin (with F. Morsingh).



IX X XI

Besides the synthesis of substances of ever increasing complexity, the other main challenge now attracting chemists working on natural products i that of biogenetic inter-relationships. H. Erdtman reviewed the chemistry of tropolones and other constituents of conifers and demonstrated their taxonomic significance. C. Fromageot described his comparative studies on lysoenzymatic proteins which contain more than a hundred amino-acid residues. In the field of steroids and triterpenes, activity shows no signs of abating; the stereochemical connexions between the two groups have been further clarified (O. Jeger and co-workers) and several important new structures, including those for the biogenetically interesting tetracyclic triterpenes butyrospermol (T. G. Halsall and E. R. H. Jones) and α-onocerin (D. H. R. Barton and K. H. Overton), were reported.

By comparison with the very rapid expansion of well-established classes of compounds, the appearance on the horizon of structurally completely novel types show signs of slowing down, as if a rich but overworked mine were increasingly reluctant to yield new seams. Nevertheless, there were some remarkable new finds; a noteworthy example is the antibiotic erythromycin, which contains the multihydroxylated fourteen-membered lactone ring (XII) consisting of seven propionate units joined in head-to-tail fashion (K. Gerzon and co-workers). Widespread interest was also aroused by the fact (see *Nature*, August 20, p. 325) that the most complex so far of the vitamins, $B_{12}$, has yielded its secrets to the combined efforts of a team of chemists and X-ray crystallo-



XII

graphers (Sir Alexander Todd, Dorothy Crowfoot Hodgkin and co-workers); in addition to the magnitude of the molecule, the presence of a porphyrin-type nucleus containing two directly linked, partly hydrogenated pyrrole rings is unique.

In the third of the Congress sections, major synthetical methods developed in recent years were given due prominence. K. Alder reviewed advances in our knowledge of the factors controlling the occurrence and direction of diene addition, knowledge which chemists owe in large measure to the work of his school. Organometallic compounds, which seem capable of unlimited development as synthetical reagents, were represented by a particularly interesting lecture by K. Ziegler, who described his recent work on the polymerization of olefins by aluminium alkyls. This has resulted in a new process for the manufacture of polyethylene which promises to be of great technical importance; another application involves a replacement reaction yielding the anti-knock agent, lead tetraethyl, together with aluminium metal of high purity. The impact of fundamental research on quite a different field of applied chemistry, that of photographic sensitizers, was outlined by L. G. S. Brooker. The spectral properties of cyanine dyes, the most effective sensitizing agents known, are highly dependent on solvent or other physical environment, and it is now well established that the sensitizing curve is closely related to the light absorption curve of the dye–silver halide complex.

Although the dominant note of the Congress was on the pure rather than the applied side of chemistry, it thus provided many forcible reminders that civilization does not depend solely on the supply of power, an aspect which features so prominently in public discussion at the present time, but also on the harnessing of energy to the production of food, clothes, fuel and an infinite variety of other things. No one attending the Congress could have been left in doubt that organic chemistry is an immensely alive subject, and that we are only at the beginning of an era in which this branch of science will wield an ever-increasing influence on our daily lives, by substituting synthetic materials for natural products and by bringing under control biological processes which have so long sustained mankind unbridled.

Whether fired by such far-reaching thoughts, engrossed in new ideas or fresh problems, or merely stimulated by personal contact with many colleagues, members of the Congress dispersed in an elated mood, and a large proportion appeared to make for other parts of Switzerland to follow up a period of mental by another of physical recreation. The interesting encounters the writer had during a fortnight's climbing in the Grisons area certainly left him with the impression that seldom can so many organic chemists have been concentrated on so high a level.

It was announced that the next International Congress of Chemistry, covering all branches of the subject, will be held in Paris in July 1957, following the centenary celebration of the Société Chimique de France.

E. A. Braude

# DUST AND HEALTH IN INDUSTRY

A DISCUSSION on "Dust and Health in Industry" was held by Section I (Physiology) of the British Association on the morning of September 1 at Bristol. It was opened by Dr. B. M. Wright (Medical Research Council Pneumoconiosis Research Unit), who dealt with the problem of measuring dust exposure in relation to pneumoconiosis of various types. Dr. Wright pointed out that, to understand the problem, it is necessary to consider some of the physical properties of dust and some aspects of the physiological behaviour of the respiratory tract. Airborne dust consists of particles of such small size that their rate of settling in air is very low, of the order of 5 cm./min. for a particle 5μ in diameter, down to rates so low as to be negligible for particles less than about 1μ. As a consequence, the size range of airborne dust particles depends upon the atmospheric conditions; in still air they will be very fine, whereas in a well-ventilated place relatively coarse particles will remain in suspension. Particles that are large enough to be visible are of little hygienic importance, so that it is not possible to judge the likely danger to health of an environment by visual inspection, and the use of an instrument is essential.

Turning to the physiological properties of the respiratory tract, Dr. Wright pointed out that it consists essentially of two parts—the upper respiratory tract, which is covered with ciliated epithelium, and the respiratory bronchioles and alveoli, which are not. Particles that settle on the ciliated epithelium will be removed within a matter of minutes or hours, whereas particles that penetrate to the alveoli may be retained indefinitely in the lung. The low settling-rate of very fine particles enables them to penetrate deeply into the respiratory tract, and the finer they are the farther they penetrate. The main mechanism by which they are trapped in the tract is sedimentation in the smaller bronchioles, although some loss of larger particles by impingement takes place in the nasopharynx and larger bronchi. The velocity of the air in the respiratory tract decreases continuously as it approaches the alveoli, where air movement is almost negligible, so that a substantial proportion of particles penetrating into the alveoli settle out and are retained. The proportion of particles retained is not much affected by the rate of breathing, because, although the increased air velocity tends to reduce the proportion of particles captured by sedimentation, impingement becomes a more important mechanism, and also the volume of air entering the alveoli is increased. It is important to realize that the penetration of particles to the alveoli has nothing directly to do with the relative dimensions of the air vessels and the particles, since the former are never less than 200μ in diameter, whereas the largest particle ever likely to penetrate to the alveolus is only about 5μ in diameter. Particles deposited in the alveoli are removed therefrom by phagocytes and are mostly deposited in the interstitial tissue, though some probably are also carried on to the ciliated epithelium and so removed from the lungs. Particles retained in the lungs, if they are relatively insoluble, will accumulate and cause pneumoconiosis. Particles deposited on the ciliated epithelium will cause no trouble unless they are soluble and irritating. Severely poisonous substances can cause general intoxication, whereas mildly irritating materials can cause chronic conditions such as byssinosis.

Owing to the wide range of particle sizes found in airborne dust, the range to be selected for sampling must be decided by the nature of the disease under consideration. If it is thought to be mainly due to irritation of the upper respiratory tract, particles up to 10 or 15μ diameter must be considered, whereas with a true pneumoconiosis only those less than 5μ are of importance.

Two main methods of assessing the quantity of dust are available—weighing and counting. The disadvantage of the former method is that it greatly overestimates the importance of large particles outside the respirable range, whereas the latter method is liable to be indeterminate, since the number of particles counted depends largely on the efficiency of the microscope used. In theory, a measurement of the surface area of dust might be of value, but practically it is difficult to obtain a measure of the true surface, and it is still necessary to confine the measurement to particles in the respirable size range. When collecting samples for microscope counting, care has to be taken that they are not distorted by the sampling instrument, so that the actual size of the airborne particles or aggregates can be judged. Methods are now available for collecting samples for gravimetric analysis, in which the larger particles are separated while sampling by a mechanism similar to that in operation in the respiratory tract.

Prof. J. Gough and Dr. A. G. Heppleston (Department of Pathology, Welsh National School of Medicine, Cardiff) then presented a paper on "The Harmful Effects of Pneumoconiosis", with particular reference to coal-workers. In the past, a high phthisis death-rate was associated with the inhalation of highly siliceous dusts, but a low rate with exposure to coal dust. Recent evidence, however, indicates that coal-mining is not such a healthy occupation as had been supposed and that tuberculosis plays an important part in the pneumoconiosis of coal-workers. Two forms of this disease may be distinguished. Simple pneumoconiosis is characterized by numerous discrete dust foci throughout the lung and represents the effect of dust alone. Complicated pneumoconiosis is often superimposed on the simple form, appearing as one or more densely fibrous black masses, and is considered to represent the combined effect of dust and tuberculosis. James has found bacteriological or histological evidence of tuberculosis in 40 per cent of these massive lesions from 245 men. When split into age-groups, however, 88 per cent of massive lesions from men less than forty showed tuberculosis, but only 29 per cent of lesions from men of sixty and more. These findings are interpreted as pointing to the tuberculous origin of massive fibrosis and suggest that, with increasing age, the infection dies out. A tuberculous element therefore exists in the massiv fibrosis of coal-workers just as in classical silicosis but in coal-workers it is largely concealed, except i the younger men. In 1,000 consecutive autopsy cases, there were 454 with massive fibrosis and, o these, 87 died from pulmonary tuberculosis but 21 from pulmonary heart disease due to vascula obliteration and emphysema caused by massiv fibrosis. It can therefore be said that indirectly tuberculosis contributes greatly to the morbidity and mortality of coal-workers.

Simple pneumoconiosis, however, is very rarely fatal but can contribute to disability in men over the age of fifty. To establish the effect of simple pneumoconiosis on coal-workers, the pathological findings in the 1,000 autopsy cases were correlated with the disability during life. 29 cases were found in which dyspnoea could be attributed only to simple pneumoconiosis, that is, after eliminating all other possibl causes for dyspnoea. This figure, however, underestimated the contribution of simple pneumoconiosis to disability because, to prove its effect, the 454 coal-workers with massive fibrosis had to be excluded and many of these had the more severe grades of simple pneumoconiosis. Free silica is not regarded as necessary for the development of the simple dust lesion of coal-workers, which bears no pathological resemblance to the classical silicotic nodule. A woman exposed for five years to the inhalation of carbon black, a very highly purified form of carbon, developed lung lesions identical with those of simple pneumoconiosis in coal-workers, thus supporting the conclusion that the reaction to airborne coal dust is non-specific. The development of the simple dust lesion in men exposed to a dust, such as coal or hæmatite, containing little free silica, therefore depends on mechanical accumulation of sufficient dust irrespective of its nature. (The precise structure of the simple dust lesion of coal-workers was then demonstrated by means of a film prepared from serial sections.) This lesion is in effect a fairly wide cylinder of vesicular tissue consolidated by dust and a little fibrous tissue, disposed around respiratory bronchioles, which are often dilated to produce the change known as focal emphysema. The mechanics of focal emphysema are interpreted on the basis of imbalance between the forces of inspiration and expiration, in which atrophy of bronchiolar smooth muscle appears to be the main factor. Dyspnoea due to simple pneumoconiosis in coal-workers can therefore be attributed to rigidity of important segments of the bronchiolar tree and to the development of focal emphysema, which may be regarded as increasing the dead space of the lung, an effect likely to be greater as the emphysema becomes more severe.

Reference was also made by Prof. Gough and Dr. Heppleston to the pathological features of the recently recognized 'rheumatoid' nodules in the lungs of coal-workers with rheumatoid arthritis. These nodules have to be distinguished from foci of complicated pneumoconiosis. It was suggested that coal-workers with rheumatoid arthritis react abnormally to the collagen produced in infective pneumoconiosis, and the non-specific inflammatory reaction, which may occur in the absence of tubercle bacilli, is believed to be the 'rheumatoid' component of these peculiar nodules.

Mr. S. Smith (Factory Department, Ministry of Labour and National Service) dealt with protection against the risk of inhalation of industrial dust. Whereas the almost instinctive reaction to the xistence of a dust hazard is to think of providing espirators, or local exhaust ventilation, these nethods are wrong as first thoughts. The fundamental method, which has been used with success in nany processes, such as bedding of pottery, grinding nd 'sand-blasting', is to substitute a harmless dust or the dangerous one. Where this is not possible, he dangerous process ought to be totally enclosed: erhaps the most striking illustration of the success hat can be achieved in this way is the control of adioactive dusts in the Atomic Energy Research stablishments. But complete enclosure, although ften possible, is not always expedient. In such cases, s near total enclosure as is possible should be btained, and suction applied to the inside of the abinet, so that the enclosure is sealed, as far as dust s concerned, by a dust-proof wall of moving air. To e effective, the air ought to be moving into the abinet at about 150 linear feet per minute. This rrangement is none other than the common fume upboard, which is to be found in every chemical aboratory; 'industrial' fume cupboards have been uilt around such plant as 'barrels' in foundries, sbestos blending benches, asbestos stock heaps, rass melting furnaces, and luminizing benches. Of ourse, most of the fume cupboards in industry are ot the fragile glass structures commonly found in aboratories; those that enclose heavy plant have to e of steel, but the principle governing their use is he same. Obviously, very large machines can be rotected in this way for very small running-costs.

When the degree of enclosure that can be achieved s small, very large air-flows are necessary to give ven moderate control of the dust; this degenerate fume cupboard' is the familiar local exhaust hood. It s often unsatisfactory for such reasons as its high unning-costs, the poor control of dust that it someimes gives, and the fact that, if the machinery works t high speed, it is usually defeated; an example of his is the recent discovery by foundry research ssociations, in conjunction with the Factory Department of the Ministry of Labour and National Service, hat the hood of the orthodox pedestal grinder where good enclosure and high air flows are common) s ineffective because the dust moves under the nfluence of the wheel rather than of the air flow.

In the past, wetting has been relied upon to prevent he emission of dust. It has been found that this is uccessful only if gentle forces are at work, as in the tirring of a slurry; with violent forces, as in grinding, r 'dunting' in the granite industry, wetting is not ffective. Suppression of an existing dust cloud by prays is very difficult and inefficient.

If none of these methods is completely effective, ne is thrown on to the last resort—personal proection of each person at risk by the provision of espirators. The performance of dust respirators is overned by British Standard 2577, and many in se are unlikely to be able to pass its stringent tests.

Reliance is placed, sometimes, on the dilution of dust cloud to a safe concentration by general entilation. Experience has shown this to be quite rong.

A protective scheme is usually built on the basis f samples having shown the existence of dangerous onditions; therefore, it is necessary to consider nethods of sampling. Research has shown that, for eneral purposes, only the thermal precipitator and bsolute methods, such as sedimentation, are reliable. Even with these, statistical sampling errors occur; nd others appear in the evaluation of the sample, in the form of counting errors, and errors due to having to allot a given particle to one of a finite number of size groups, instead of being able to give the size distribution in a sample as a continuous function. Therefore, to express results to three, and sometimes four, significant figures, as is common in the literature, is patently absurd; and the existing tables of 'maximum allowable concentrations' (which give results to three significant figures) are of little value. All workers in this field work to two numerical values for each material, whether they realize it or not; the lower is the upper limit of concentrations that they know to be safe, and the upper is the lower limit of those that they know to be dangerous. The gap between the two limits is always wide, because there is a lack of fundamental information about which parameters make a given dust dangerous, and about the finer details of the mechanism whereby the dust causes its damage to the lung. The gap can become narrower as more fundamental information is discovered.

Dr. R. S. F. Schilling (Department of Occupational Health, University of Manchester) described the results of a recent investigation of byssinosis among Lancashire cotton workers. He gave a brief review of cotton processes and described the signs and symptoms of the disease. There were no specific X-ray changes in the lung fields, and diagnosis depended on the typical history of breathlessness and chest tightness on the first working-day of the week. Because of the lack of specific signs, the existence of byssinosis as an industrial disease has been doubted. Another masking feature is the high incidence of chronic respiratory disease in the general population of the cotton towns of Lancashire. However, by using a modified Gaensler apparatus to measure the volume of air expelled during the first 0·75 sec. of a forced expiration, the 'maximum voluntary ventilation' was calculated and gave an indication of the degree of disability caused by byssinosis. A survey made in the Oldham area against controls from two engineering factories disclosed that 60 per cent of all persons at risk were suffering from the disease. In the worst cases, the maximum voluntary ventilation was only 60 litres/min., whereas that for controls of the same age was more than 100 litres/min. Out of 190 men between forty and sixty years of age working in card and blow rooms, some 26 were seriously disabled by byssinosis. The disease principally occurred in card rooms, and its prevalence was inversely related to the distance of the workers from the carding engines. Byssinosis presents a number of problems. Is it due to a specific allergen? What is the origin of the causative agent? Is it in the cotton, or the trash, or in the concomitant moulds or bacteria? No maximum allowable concentration of cotton dust is known, or has been suggested.

Dr. C. L. Sutherland reviewed the position from the point of view of national insurance in Britain. He remarked that simple pneumoconiosis among coal miners is quite unimportant; and that statistics show that miners' wives suffer from heart disease almost to the same extent as their husbands. In reply, Dr. Heppleston emphasized that the clinicopathological correlation indicates that simple pneumoconiosis can cause disability, but the figures give no indication of frequency. Furthermore, the occurrence among miners' wives of a high mortality from heart disease and pulmonary tuberculosis does not adversely affect the arguments relating to the nature of dust disease in the coal-workers themselves.

Dr. B. Klinge queried the apparently different descriptions of the mechanism of deposition of dust in the lung as given by the different speakers, and wondered why Dr. Schilling had suggested no mechanism to explain how cotton dust attacked the lung. He regretted that Mr. Smith had limited the scope of his discourse to factories, since the principles he enunciated were plainly relevant to other dust problems, such as atmospheric pollution. Dr. Wright and Dr. Heppleston explained that the difference between the mechanisms they had described was only apparent, and was due to the fact that the latter had dealt with phenomena in the depths of the lung, whereas the former had not so limited himself. Dr Schilling said that he had not given the explanation requested, because none is known. Mr. Smith replied that the subject of dust is so vast that he had had to limit his examples to those of which he had had substantial first-hand experience.

Mr. B. W. A. Crutchlow remarked that the slide of a carding engine showed an obsolete exhaust. Dr Schilling agreed and said this showed the dusty nature of the work, but a much improved exhaust has been developed by the Shirley Institute, which with the Factory Department, is paying particula attention to methods of dust control in card rooms

---

# UTILIZATION AND EVALUATION OF GRASSLAND

THE first session of Section M (Agriculture) at the meeting in Bristol of the British Association was devoted to a discussion of the utilization and evaluation of grassland. The session was opened by Mr. R. A. Hamilton, who said that increases in world population will call for increased output by agriculture. As standards of living improve, there is a tendency for people to eat less tillage crops and more meat and dairy products. This will put an ever-increasing strain on the supply of basic food nutrients, because the efficiency of conversion of plant foods to animal products is low. With about two-thirds of the agricultural land of the world under grass, it is vital that there should be efficient utilization, especially as grass that is well managed can produce greater yields of nutrients for livestock than almost any other crop and the cost of grass nutrients is low. The energy of grass has been estimated to cost, under recent British conditions, £11–14 per ton of utilized starch-equivalent, or £17 when preserved as silage and £20 as hay. By the same estimate, grazed kale costs £17, oats £28, artificially dried grass £40, and dairy cubes £54 per ton of starch-equivalent.

Where a variety of stock is consuming the grass and where other foods are sometimes given, it is difficult to measure the output of the grassland. The food requirements of the stock may, however, be estimated on the basis of their size and production together with the value of any other foods, and the contribution of the grass may then be determined by difference. This method has many shortcomings, but for comparative purposes is one of the most useful at present available, and by its means a working party of the Organization for European Economic Co-operation recently estimated that the yield of starch-equivalent per acre from grassland in various European countries was: Netherlands, 26·2 cwt.; Denmark, 22·3 cwt.; Belgium, 20·0 cwt.; Norway, 19·0 cwt.; West Germany, 17·2 cwt.; Great Britain, 16·7 cwt.; and France, 11·1 cwt. The low value for Great Britain may be partly due to an over-estimate of the value of the large amounts of concentrates used. Surveys show that, with good management, yields of 30 or even 40 cwt. can be obtained in Britain; few arable crops will produce values of this order. It has, however, been estimated that even in New Zealand, with its ideal climate and highly specialized grassland dairy industry, utilization of grassland is still only 50 per cent of the potential.

Maximum utilization will be achieved with a careful system of management which includes the longest possible grazing season and an efficient system of storing all grass produced in excess of immediate requirements. This was illustrated diagrammatically by Mr. Hamilton from the management followed in fat-lamb production in New Zealand. By this system 400–600 lb. of meat is produced annually per acre In New Zealand the fit between production and the requirements of dairy cattle is less close than for fat lambs, but grass in some form nevertheless provides for the full needs of most dairy herds. In consequence, New Zealand can provide lamb and butter at lower costs than any other country in the world

In Britain the liquid milk market requires a more even spread of milk production through the year yet the grazing season is considerably shorter than in New Zealand. Mr. Hamilton accordingly stressed the need to lengthen the grazing season and to secure efficient grass storage for winter feeding. Methods of grass conservation are, therefore, of very great importance in the British economy. With any of the recognized methods there will be losses of nutrients, and it has been estimated that average losses of starch-equivalent are of the following order: artificially dried grass, 5 per cent; silage, 22–35 per cent; hay, 40–45 per cent. These all depend somewhat on the method employed and the efficiency with which it is applied; clearly at times the losses may be much higher. At present, hay and silage account for more than 95 per cent of all grass conserved in Britain and, of this fraction, 90 per cent is still in the form of hay. Silage-making is more suited to the British climate than hay-making, and Mr. Hamilton was of the opinion that we should be making 15 million tons of silage instead of the 2½ million tons being made at present.

Before a completely efficient system of grassland utilization can be achieved, Mr. Hamilton concluded, there are many problems that have to be overcome Perhaps among the most important of these are the increased incidence of hypomagnesæmia, bloat, infertility, various allergies and parasitism that has followed more intensive methods. Unless these problems are solved, it will not be possible for grass to play its potentially important part in lowering the cost of production of ruminant products.

The question, raised by Mr. Hamilton, of the difficulty of measurement of the output of pastures has recently received considerable attention. Three types of approach have now been tried, each with some success; they are based either on a measurement of the amount of grass removed from the field, the amount consumed by the cow, or of the production of the cow. Mr. C. Line (National Institute for

Research in Dairying, Shinfield) talked about these techniques and described an experiment that has recently been carried out over three seasons at Shinfield. A field was divided into twenty-four paddocks, each 20 yd. wide and 100 yd. long, and each paddock was sown down to a ley consisting of either perennial ryegrass, or meadow fescue or cocksfoot, each with white clover. During the experiment one milking cow was allocated to each paddock, twelve paddocks being tested at any one time. Ample grazing was allowed by strip-grazing with an electric fence; they received no other food. The primary object of this experiment was to develop a satisfactory technique for measuring the output of leys with the milking cow, and, with limitations, this was achieved. Under the particular conditions at Shinfield, the meadow fescue ley proved superior to those with ryegrass or cocksfoot, probably due to a higher clover content and to superior palatability. Although this result cannot be taken as generally applicable, it is interesting to find that similar comparative values were obtained when the results were expressed as grazing days obtained or milk yield per acre. Mr. Line felt that, because of its simplicity, measurement in grazing days per acre has the greater application for experiments of this type.

In view of Mr. Hamilton's insistence on the need for increased silage production, it was logical to conclude the morning with a consideration of the nutritive value of silage. In dealing with this question, Dr. C. C. Balch (Shinfield) emphasized that, of the 2½ million tons of silage now made annually in Britain, a considerable proportion is given to cattle and that to a large extent its value to the farmer is measured by its use for milk production and the part it can play in dairy farming systems. Good silage can be made only from good herbage, but good herbage can be satisfactorily ensiled by a variety of methods. With all methods of ensiling there will be losses of nutrients due to fermentation and seepage of substances in solution. Together these may amount to 40 per cent of the dry matter. Methods using preservatives such as sodium metabisulphite will reduce the losses due to fermentation, and wilting of the crop before ensiling will reduce both losses. In a pilot experiment at Shinfield, the loss of carbohydrate was approximately halved by the use of metabisulphite; but unfortunately wilting and the metabisulphite method do not appear to be always compatible.

Provided the method of ensiling is efficient and does not lead to the development of high temperatures, the digestibility of the finished silage will not differ very markedly from that of the crop; any changes are usually towards a lowered digestibility resulting from the loss of readily soluble constituents. Excessive heating lowers the digestibility of the protein. Thus silages of similar nutritive value can be made by different methods, and the choice of method depends largely on how it fits in with the equipment and management used on a particular farm. Among advisory workers there is an urgent need for a simple means of relating the nutritive value of silage to its gross chemical composition. The evidence available at present suggests that the crude fibre content may prove to be a satisfactory guide for practical purposes.

The impression given by the speakers, and confirmed in the short discussion, was that the efficiency of utilization of grassland could be improved by management changes giving a prolonged grazing period and the making of increased amounts of good silage.

# PEACEFUL USES OF ATOMIC ENERGY

## BIOLOGY AND MEDICAL SESSIONS AT GENEVA

By Dr. L. F. LAMERTON

Physics Department, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

THE sessions of the Geneva Conference on the Peaceful Uses of Atomic Energy devoted to applications in biology and medicine were of a rather different nature from the others. In the first place, the field was wider, covering a large number of specialities, and secondly, since relatively little material in the subject had been classified, there could be none of the disclosures of information which added so much to the significance of the other sessions. The success of the biological and medical side of the Conference had therefore to be judged by the extent to which a real understanding could be established between the workers attending from the various parts of the world. That this was achieved reflects great credit on the various governments and individual delegates, not only for the quality of the material presented, but also because there was no attempt to make political issues out of any of the subjects under discussion.

For the sessions assigned to biology and medicine, nearly three hundred papers were submitted by twenty-four governments. About a hundred and fifty of these papers were submitted by the United States of America, covering a very wide range of topics, and including both reviews and reports of special investigations. The United Kingdom submitted twenty-one papers, the majority being in the nature of reviews. The U.S.S.R. submitted eighteen papers, mainly reviews of work carried out by Soviet investigators, and therefore of special interest to Western workers, for whom coverage of Soviet scientific journals is generally very incomplete.

In the time allotted it was possible to plan for oral presentation only about one-third of the papers submitted (101 papers from nineteen countries and three specialized agencies of the United Nations), and even so the length of time allowed for presentation and for discussion was much less than ideal for a scientific meeting.

The main subject headings were as follows: "Radioactive Isotopes and Nuclear Radiations in Medicine" (therapy, one session; diagnosis and studies of disease, two sessions); "Biological Effects of Radiation" (modes of radiation injury and radiation hazards, one session; mechanisms of radiation injury, protection and recovery, one session; genetic effects—human implications, half session); "Radioactive Isotopes and Ionizing Radiations in Agriculture" (radiation-induced genetic changes and crop improvement, half session; tracer studies in agriculture, one session); "Radioactive Isotopes in Physiology and Biochemistry" (animal physiology and plant biochemistry, one session; general biochemistry, one session); "Safety Standards and Health Aspects of Large-scale Use of Atomic Energy" (radiation safety recommendations and control, hazards related to uranium mining, one session; hazards related to reactions and chemical processing, ecological problems related to reaction operation, one session).

In addition to these sessions, biological and medical subjects were included in the plenary sessions of the Conference, and certain of the evening lectures were devoted to biological topics.

In a short review it is clearly not possible to summarize each of the sessions, but only to give general impressions. One of the strongest impressions was of the progress being made in agriculture by radioactive tracer studies. Some very interesting contributions came from the U.S.S.R., where there has been a large effort put into the study of the efficiency of fertilizers, as well as into more basic problems of translocation of materials in plants. The work reported indicated real practical advantage gained from these studies, and corresponded well with work reported from the United States, the United Kingdom and other countries. This certainly represents a field of study where international collaboration can develop, with considerable mutual advantage. Much effort has also been put into studies of the method of crop improvement by the use of radiation-induced genetic changes, as shown in reports from Sweden, Norway and the United States of America.

In the session devoted to the therapeutic use of radioactive materials and nuclear energy, a number of different aspects of the subject were discussed; but progress was not so obvious as, for example, in the papers dealing with agricultural applications. Radioactive isotopes have now an established place in radiotherapy, and the large number of reports submitted showed that they are being used in an increasing number of centres throughout the world; but any spectacular advance must depend on finding means for a high degree of localization of the isotope in the desired tissue. Papers from Switzerland and France described recent clinical experience with particulate radioactive materials which permit, in certain sites and with certain limitations, a localization of irradiation. Except for radioactive iodine in the thyroid gland the problem of a high degree of localization by metabolic processes remains unsolved, although a paper from the United States, reporting some preliminary studies on the labelling of antibodies, indicated a possible approach. Another paper from the United States was read on preliminary clinical experience with brain tumours using neutron-capture therapy, a technique that may prove to have more general technical applications.

The fundamental advances that radioactive isotopes have made possible in biochemistry and physiology were described in the sessions dealing with diagnosis and studies of disease as well as in the more specialized sessions concerned with general physiology and biochemistry. Many topics were discussed. From the direct clinical point of view there was much interest in the work reported from the United States on the use of radioactive iron in the study of various types of anaemia, and also in the United Kingdom's contributions on absorption studies of vitamin $B_{12}$ labelled with radioactive cobalt. From India there was a report on autoradiographic methods being used to study the action of certain drugs in leprosy treatment.

The mechanism of photosynthesis was the subject of papers from both the U.S.S.R. and the United States of America, and nucleic acid studies from the United States of America and the United Kingdom. Papers from the United States and from Brazil dealt with the application of radioactive materials in public health problems. Much important information has already been gained on the habits of insect populations, such as range of flight, and the discussion following these papers demonstrated the wide application that these techniques could have in the future.

A number of countries contributed papers to the subject of the effects of radiation and radiation hazards. The Soviet workers put a great deal of emphasis on the neurological changes produced by radiation. They regard these changes as being among the most sensitive primary effects of radiation, and have considered them in setting up their radiation protection regulations. Difficulties of language, in spite of a very adequate simultaneous translation service, prevented a full discussion on some of these matters during the meeting, but informal contacts were made which it is hoped will continue.

In spite of some apparent difference in approach, it was encouraging to find that the maximum permissible dose recommendations of the U.S.S.R. are similar to those set out by the International Committee on Radiological Protection. The main difference was the length of time over which the exposure can be integrated. Whereas the International Committee recommends 0·3 rem per week as the maximum permissible dose, the U.S.S.R. take a value of 0·05 rem per day. Although there are other differences in the approach of the U.S.S.R. and the International Committee on Radiological Protection on the protection of radiological workers, the general basis is remarkably similar.

Two papers were read, in the plenary sessions, concerned directly with the effects on humans of large over-exposure arising in reactor accidents. From the United States a report was given on four exposed workers, the greatest dose received being about 190 r., mainly gamma radiation, and from the U.S.S.R., where two workers were reported to have received 300 r. and 450 r., respectively. Very full clinical reports were presented. None of the accidents proved fatal, though the U.S.S.R. workers became seriously ill. The number of cases of known human exposure to radiation, without other forms of injury, and with adequate clinical data, is so small that reports of such cases are of extreme value.

It was natural that there should be a great deal of interest in the problems of the genetic effects of radiation. On this subject three papers were read, two from the United States and one from the United Kingdom. In spite of large programmes of work on experimental radiation-induced mutations, the paucity of knowledge, so far as population genetics and in particular human population genetics is concerned, is very evident. There is need for a wider field of research, and one that will include studies of the genetics of human populations in various localities where the natural radiation background is abnormal. This again is an international problem, where co-operation through one of the international agencies could be of the greatest value.

In the sessions devoted to the health aspects of the large-scale use of atomic energy, it was demonstrated that in atomic energy installations the plant personnel need suffer no serious exposure to radiation. In normal operating conditions exposure can be kept down to a small fraction of the maximum permissible limit, and even in the case of reactor accidents exposure can normally be adequately controlled.

A problem of greater concern is that of the possible spread of radioactive materials over wide regions, so that large populations might be subjected to risk. The problem is not yet of a magnitude to constitute a serious hazard; but it is important that there be available as soon as possible basic data on the uptake of various radioactive substances in plant, fish and animal forms. Over the past few years much information has been obtained in the United States, but not all has been readily available. It was, however, presented in a series of papers in the last session of the biological and medical meetings, which will provide most valuable reference material.

# OBITUARY

## Prof. Wilfred Smith

Wilfred Smith, John Rankin professor of geography in the University of Liverpool, died suddenly while preparing to attend a university function on September 27 at the age of fifty-two. Prof. Smith had been closely associated with the University of Liverpool all his life. He entered as an undergraduate and remained as a postgraduate research worker, lecturer, senior lecturer, professor of geography, and since 1953 Dean of the Faculty of Arts.

Wilfred Smith belonged to that distinguished band of students that gathered around the late Prof. P. M. Roxby, the first holder of the John Rankin chair at Liverpool. The impress of the great teacher was clearly seen in everything Smith wrote about and lectured upon. He began his life-long interest in the location of industry with an important study of the iron and coal resources of China—a country in which Roxby had developed a special interest. In later years, and more particularly in view of the disturbed conditions in the Far East, Prof. Smith concentrated his attention on the homeland, and in 1949 there appeared the standard work on the location of industry in Britain under the title of "The Economic Geography of Great Britain". This work well illustrates the author's technique. It shows him to be a meticulous and painstaking worker with a passion for fact and, particularly, for pattern in fact. His references were always abundant and exact, and his writing precise and direct. This work makes, in fact, a new approach to economic geography in the Roxby tradition—the industrial landscape seen as an expression of historical as well as of physical factors.

In later years Prof. Smith directed the attention of his students more and more towards the economic geography of Merseyside, and the visit of the British Association to Liverpool in 1953 provided the opportunity for the publication of "A Scientific Study of Merseyside", edited by Prof. Smith and to which he himself made a most valuable contribution.

He was one of those modest men who gave practically all his time to academic work; he seldom rested. When not engaged in research, he was busy as an administrator, or actively engaged in teaching. At the time of his death he was president of the Institute of British Geographers, which now includes within its membership practically all teachers of geography in the British universities. In spite of physical handicaps he succeeded in travelling widely, particularly in western and southern Europe. He will be greatly missed by his professional colleagues in every university, for he never spared himself in furthering the interests of his subject; and in particular by his own university, to which he was deeply devoted and to which he had given a lifetime's distinguished service in so many capacities.

E. G. Bowen

# NEWS and VIEWS

## Embryology at the Carnegie Institution of Washington: Dr. G. W. Corner, For.Mem.R.S.

Dr. George W. Corner will retire on January 1 from his post as director of the Department of Embryology of the Carnegie Institution of Washington and will be succeeded by Prof. J. D. Ebert, professor of zoology in Indiana University, Bloomington, Indiana. Dr. Corner was elected this year a foreign member of the Royal Society, and a note was published then on his work and activities (*Nature*, May 14, p. 838).

### Prof. J. D. Ebert

Prof. James D. Ebert, who is not yet thirty-four, graduated in 1942 from Washington and Jefferson College, Washington, Penn., and then spent nearly four years on active duty as an officer in the United States Naval Reserve. During 1949–50 he held an Adam T. Bruce fellowship in biology at Johns Hopkins University, gaining his Ph.D. degree, then spent a year as an instructor in biology at the Massachusetts Institute of Technology, and in 1951 joined the Department of Zoology of Indiana University, to set up a programme of research and advanced teaching in experimental embryology. Prof. Ebert's research work has been directed toward an understanding of the mechanism of synthesis and interaction of tissue-specific proteins in development. He has employed the techniques of immunochemistry to throw light on the processes involved in the formation and localization of the contractile proteins, actin and myosin, in the developing heart, and recently he has made an analysis of the metabolism of the heart-forming regions of the early embryo, paying special attention to the mitochondria and their role in fibrogenesis. Since 1952 he has combined the classical methods of experimental embryology—transplantation, organ culture, etc.—with radiobiological techniques in an investigation of the growth-regulating mechanisms of the chick embryo, and these experiments suggest that, at the outset, growing organs can utilize specific macromolecules almost intact without breaking them down into simpler building blocks. The Department of Embryology of the Carnegie Institution of Washington is situated in Baltimore, Maryland, and is well known for its investigations of the morphology of the human embryo and the comparative physiology of the reproductive system, the morphological research being centred on the Department's superb collection of human embryos. Under Prof. Ebert's leadership it is expected that workers in the Department will pay increasing attention to the study of the basic mechanisms of differentiation, growth and morphogenesis of the early embryo, using the technical advances in such fields as immunochemistry, protein physical chemistry and virology to link up our knowledge of reactions at the cell group and tissue level with the reactions of specific molecules.

### Hunsaker Chair of Aeronautical Engineering at the Massachusetts Institute of Technology:

### Prof. W. R. Hawthorne

PROF. W. R. HAWTHORNE, Hopkinson and Imperial Chemical Industries, Ltd., professor of applied thermodynamics in the Department of Engineering, University of Cambridge, is at present on leave of absence at the Massachusetts Institute of Technology and has been appointed for the current academic year to a new chair at the Institute, the Jerome Clarke Hunsaker chair of aeronautical engineering. Prof. Hawthorne's principal interests are in the fields of aircraft propulsion and advanced fluid mechanics, and at the Institute he will divide his lecturing between the Departments of Mechanical and Aeronautical Engineering. During his tenure he will deliver the Minta Martin Aeronautical Lecture. The Hunsaker chair was established last year in honour of Prof. J. C. Hunsaker, founder and for many years head of the Aeronautical Engineering Department at the Institute and a leading figure in American aviation. He retired in 1952 but is still closely associated with the Institute. The founding of the chair has been largely due to Major Lester D. Gardner, of New York, an alumnus of the Institute and one of the founders of the Institute of the Aeronautical Sciences; more than 360,000 dollars has been raised, and it is hoped to increase this eventually to 500,000 dollars.

### L. G. Groves Memorial Prizes and Award of the Air Ministry

Two L. G. Groves Memorial Prizes and an Award are made annually by the Air Ministry from a fund established in 1946 by Major and Mrs. Keith Groves in memory of their son, Sergeant Louis Grimble Groves, R.A.F.V.R., a meteorological observer who lost his life on a weather flight in 1945. The recipients this year are as follows: *Prize for Aircraft Safety*, to Squadron-Leader J. Harvey (technical staff, Headquarters, Fighter Command) for designing an alteration to the fuel system of the Meteor night-fighter, which provides the aircraft with automatic operation of the fuel system from all tanks, in place of the original arrangement of individual tank selection by the pilot, and thereby greatly enhances its safety; *Prize for Meteorology*, to Dr. F. J. Scrase (principal scientific officer and leader of the Instrument Development Division of the Meteorological Office) for his research on turbulence in the upper atmosphere and theoretical investigation of the errors, due to radiation and lag, of radiosondes, studies which are closely related to practical problems of aviation and air navigation, and also for his work as president of a sub-commission of the World Meteorological Organization responsible for the new "Guide to International Meteorological Instrument Practice"; *Awar for Meteorological Observers*, to Flight-Lieutenant J Formby (of Short Bros. and Harland, Ltd.), for hi work since September 1952 in carrying out meteorological ascents under contract with the Air Ministry amounting to more than 450 flights in Spitfire aircraf from the R.A.F. Station, Woodvale, Lancs, and involving exceptional ability both as a pilot and as a meteorological observer.

### Central Advisory Water Committee

MEETINGS of the Central Advisory Water Committee, appointed by the Minister of Housing and Local Government, are being resumed, and the first will be held on October 31. The Minister, Mr. Duncan Sandys, is chairman of the Committee, and the vice chairman is the Parliamentary Secretary, Mr. William Deedes. The Committee was first set up in 1946, under the Water Act, 1945, and has issued a series of reports on river pollution, water softening, gathering grounds and land drainage. Its sittings were suspended in 1952, and its revival has necessitated the appointment of new members, the terms of appointment of the previous members having lapsed. The members are: Sir David Brunt, secretary and vice-president, Royal Society; Mr. John Cockram, chairman, Water Companies Association; Lieut.-Col. J. Godman, chairman, Severn River Board; Coun. A. Gorman, chairman, Metropolitan Water Board; Sir Arthur Heneage, president, River Board Association and chairman of the Lincolnshire Branch, Country Landowners Association; Dr. N. R. Hood, director, British Paper and Board Industry Research Association; Mr. H. E. Hopthrow, assistant secretary, Imperial Chemical Industries, Ltd.; Sir Reginald Kerr, chairman and general manager, British Transport Waterways; Prof. W. B. R. King, sometime professor of geology, University of Cambridge; Mr. W. O. Knill, vice-president, Association of Waterworks Officers; Mr. C. E. Lucette, manager and secretary, Manchester Ship Canal Co.; Mr. A. G. McLellan, engineer and general manager, Sunderland and South Shields Water Co.; Canon W. Marsden, chairman, Public Health Committee, Rural District Councils Association; Mr. G. S. Mason, chairman, Pollution Prevention Committee, River Boards Association; Mr. W. A. Muddell, chairman, Trent River Board; Prof. J. Proudman, sometime professor of oceanography, University of Liverpool; Lord De Ramsay, president, Association of Drainage Authorities; Mr. J. H. T. Stilgoe, engineer, Liverpool Water Undertaking; Mr. A. Titherley, director, Mid-Kent Water Co.; Ald. J. R. Wardell, past president, British Waterworks Association; Mrs. Charles Williams, chairman, Public Health Committee, Cornwall County Council; Mr. Harold Woolley, vice-president, National Farmers Union; Ald. R. O. Yates, president, British Waterworks Association; *Secretary*, Miss M. E. Petzsche, Ministry of Housing and Local Government; *Assistant Secretary*, Mr. G. D. Vaughan, Ministry of Housing and Local Government.

### Photobiology Group: Inaugural Meeting

THE inaugural meeting of the Photobiology Group was held in Bedford College, London, on October 3, and about seventy members participated. A series of review papers was presented on different aspects of the biological action of light. Dr. E. J. Bowen (Oxford) opened the meeting with an account of work on triplet states in excited molecules, in which he demonstrated some colourful experiments showing fluorescence and phosphorescence in solids, and energy transfer in solid mixtures; the possible mportance of such phenomena in biology was discussed. Dr. R. Hill (Cambridge) followed with an account of recent work on photosynthesis. He pointed out the sequence of biochemical processes in the breakdown and synthesis of carbohydrates, nvolving phosphorylated intermediates and adenosine triphosphate. His comparison of the structure and properties of chloroplasts and mitochondria led to interesting discussion of the possible influence of physical structure on the chemical processes which these regulate. During the afternoon session Dr. W. A. H. Rushton (Cambridge) gave a stimulating review of recent physiological work on visual pigments, including a recorded demonstration of the electrical response from the optic nerve of a frog on change of illumination, in contrast to the absence of signal during steady illumination. In the final paper, Mr. J. S. Preston (National Physical Laboratory, Teddington) gave an account of methods used for the absolute standardization of light meters. At the conclusion of the papers, a business meeting was held at which it was decided to establish the Photobiology Group on a permanent basis; to hold two meetings of this kind a year; and to affiliate with the Comité International de Photobiologie. Further information about future activities can be obtained from Dr. E. M. F. Roe, Chester Beatty Research Institute, Fulham Road, London, S.W.3.

## The Woodhull Lecture at the Royal Institution

The late Miss Z. M. Woodhull, of Norton Park, near Tewkesbury, who was a life-member of the Royal Institution, Albemarle Street, London, gave practical form to her interest in the improvement of racial qualities in future generations and her attachment to the Royal Institution by making a bequest to be used by the Institution for the furtherance of the study of eugenics. The managers of the Royal Institution, as a first step in carrying out Miss Woodhull's wishes, have, after consultation with the trustees of her estate, arranged for lectures to be given from time to time on aspects of eugenics. The first Woodhull Lecture will be delivered at the Royal Institution at 6 p.m. on October 27 by Prof. J. B. S. Haldane, on "The Prospects for Eugenics". He will discuss how the earlier eugenists were over-hopeful as to the possibilities of rapid racial improvement; that the fact of mutation makes the permanent 'purification' of a race impossible with our existing knowledge; how a large reduction in congenital abnormalities may eventually be achieved; and the impact of atomic nuclear reactions upon the study of genetics.

## Recent Gifts to the University of Oxford

The University of Oxford has announced the receipt of gifts and grants amounting to £100,000 for a wide variety of purposes. The largest is £52,000 from the Rockefeller Foundation towards the cost of providing research laboratory facilities and equipment for the use of the regius professor of medicine at the Radcliffe Infirmary. Arthur Guinness, Son and Co., Ltd., is increasing to £4,000 a year the sum of £2,500 a year for seven years which they previously covenanted to pay for the three research fellowships in microbiological chemistry in the Department of Biochemistry. Other sums include 2,000 dollars from the National Council to Combat Blindness, Inc., towards the purchase of apparatus for research at the Nuffield Laboratory of Ophthalmology; 10,000 dollars from the International Bank for Reconstruction and Development for a survey of British experience in the management of capital investment overseas, which is to be carried out at Nuffield College; £4,850 from the Nuffield Foundation for research work in the Department of Human Anatomy; £700 a year for seven years from Major H. W. Hall to make possible the purchase of an optical spectrograph for use in the research laboratory for archæology and the history of art; and £1,000 a year for seven years from the British Oxygen Co., Ltd., for the continuation of low-temperature research in the Clarendon Laboratory.

## Preservation of the Sheld-Duck in Germany

In the annual report for 1954 of the International Committee for Bird Preservation (pp. 66; from the British Museum (Natural History), 1955; 2*s*. 6*d*. net) a noteworthy example is given of the help afforded to bird-lovers by one of the Armed Services. When Heligoland was given up as a bombing range by the Royal Air Force in 1951, it was agreed with the Government of the German Federal Republic that the range should be transferred to the Grosse Knechtsand in the mouth of the Elbe. As a result, large numbers of sheld-duck were being destroyed, and there was a real possibility that the species would be exterminated. The matter was referred to the Secretary of State for Air, who was informed that the sheld-duck use the sand-banks of Grosse Knechtsand during their moulting season in July and August; the duck are flightless during this season, which is thus the season of danger. Almost immediately the Secretary of State announced that "new arrangements will be made for the use of the range during the next moulting season. Only practice bombs will be dropped containing only a small charge to set off a smoke marker, which will mean that there will be no blast effect. The Royal Air Force will co-operate with ornithologists under arrangements to be made with the British Section of the International Committee, to inspect the range before and after bombing has taken place to establish its effect on the Sheld-Duck. By these measures there is every hope that in the future the species will be able to moult without being seriously molested".

## Protection from Radioactive Isotopes

The increased applications of radium sources and the change in the maximum permissible dose have necessitated a revision of the radium protection code given in Handbook 23 of the United States National Bureau of Standards. Furthermore, the nuclear reactor has made available other high-energy, relatively long-lived, gamma-ray emitters—for example, cobalt-60 and cæsium-137, which are now coming into general use. The National Committee on Radiation has accordingly issued Handbook 54, "Protection against Radiations from Radium, Cobalt-60, and Cesium-137", prepared by Subcommittee 9, which supersedes the previous Handbook. The general principles outlined, though referring specifically to the three sources, are also applicable to other gamma-ray emitters and should prove useful as a preliminary guide until these other emitters are given separate treatment. Industrial applications are not considered; the medical applications discussed cover interstitial, intracavitary and surface treatments, and teletherapy (that is, therapeutic irradiation with collimated gamma-rays); and in the non-medical applications, specific consideration is given to the uses of sources in instrument calibration, research and civil defence exercises. Radiation hazards can be significantly reduced by the proper use of suitable facilities, and details of appropriate equipment for the safe handling, storage and transportation of the radioactive materials are given together with emergency measures to be taken when accidents such as spilling occur. The disposal of radioactive materials is not dealt with. The Handbook concludes with several tables and graphs giving data from which a worker can calculate, to suit his particular purpose, the correct arrangement and barrier thicknesses of concrete, iron or lead for any one of the three sources.

## Courtaulds' Scientific and Educational Trust Fund: Postgraduate Research Scholarships for 1955

THE Courtaulds' Scientific and Educational Trust Fund has recently announced the award of postgraduate research scholarships for 1955. Scholarships in a branch of science related to the textile, plastics and allied industries (maximum of £400 for one year only, but renewable for further periods) have been awarded to the following: J. D. Coombes, University of Nottingham; J. H. N. Hill, The Queen's University, Belfast (renewal); G. Holden, University of Manchester; G. R. Kotten-Kaye, Royal College of Science, Imperial College of Science and Technology, London (renewal); F. Nyman, University of Cambridge; J. H. Oxley, University College, London (renewal); M. T. Pope, University of Oxford; P. R. Sewell, University of Birmingham (renewal); R. R. Sheldon, University of Liverpool; and T. C. Stening, King's College, London (renewal). Postgraduate research scholarships in textile technology, tenable for two years (£320 the first year and £360 the second) have been awarded to the following: C. B. Chapman (third-year renewal), Miss M. M. Forrester, A. F. Greenwood (third-year renewal), D. R. Hardisty (third-year renewal), J. Hope, A. T. Peters and A. Selwood (second-year renewal). The holders of these latter scholarships have all chosen to do their research at the University of Leeds, except Mr. Hardisty, who will work at the Manchester College of Technology.

## Mond Nickel Fellowships for 1955

THE Mond Nickel fellowships for 1955 have been awarded to the following for study in the fields indicated: D. H. Butler (Phosphor Bronze Co., Ltd.), production of copper and its alloys, with particular attention to foundry methods, in Europe and in America; R. W. N. Dron (Rhoanglo Mine Services, Ltd.), organization of research and its relation to production in extraction metallurgy in the United Kingdom and North America; W. F. Duncan (British Aluminium Co., Ltd.), the design, layout and operation of continuous strip mills and, in particular, metal behaviour, properties and quality, roll lubrication and cooling, and the development of automatic controls; R. H. Hannaford (British Iron and Steel Research Association), organization and practice in the ferrous foundry industry in Europe and the United States, with particular reference to layout, mechanization and the application of management techniques; R. J. Harbord (John Lysaght's Scunthorpe Steelworks, Ltd.), the development of continuous casting in the non-ferrous industry an its application to the production of steel.

## Institute of Metal Finishing: Officers

OFFICERS of the Institute of Metal Finishing fo the session 1955–56 are as follows: *President* R. A. F. Hammond; *Immediate Past President* Prof. J. W. Cuthbertson; *Vice-Presidents*, Dr. S. G Clarke, Dr. T. P. Hoar, Dr. L. B. Hunt, R. W. Nicol H. Silman, A. Smart and A. W. Wallbank; *Honorary Treasurer*, F. L. James; *Honorary Secretary*, Dr. S Wernick.

## Announcements

MR. W. STRATH, at present serving as a Third Secretary in H.M. Treasury, has been appointed a full-time member of the Atomic Energy Authority. Sir Rowland Smith, chairman of the Ford Moto Co., and Mr. C. F. Kearton, a director of Courtaulds, Ltd., have been appointed part-time members. This brings the membership of the Authority up to the limit of ten, other than the chairman, laid down in the Atomic Energy Authority Act, 1954. Mr. Strath will be largely concerned with the Authority's relations with industry, with overseas atomic energy organizations and with raw material procurement.

A CONFERENCE on "Cloud Physics", arranged jointly by the Physical Society and the Royal Meteorological Society and organized by Prof. P. A. Sheppard, will be held in the Department of Meteorology, Imperial College of Science and Technology, Exhibition Road, London, S.W.7, during January 4–5. A number of leading workers in this field have been invited from the United States, Australia and the Continent of Europe. Further information can be obtained from the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7, marked for the attention of Miss E. Miles.

THE Worshipful Company of Glass-Sellers of London is offering up to four scholarships in glass technology, tenable at the University of Sheffield, which in suitable circumstances will be eligible for supplementation by the Ministry of Education up to the full value of State scholarships. The scholarships will be awarded by examination, for which candidates will take papers in chemistry, physics and pure mathematics (two as primary subjects and one as a secondary subject) together with an English language paper. Entry forms (to be completed by January 16) and further information can be obtained from the Registrar, University, Sheffield 10; the examination will begin at the University on April 9.

THE National Science Foundation, Washington, D.C., has appointed the following three programme directors: Dr. Helen S. Hogg, on leave of absence from the University of Toronto and the David Dunlap Observatory, to be programme director for astronomy in the Division of Mathematical, Physical and Engineering Sciences; Dr. Vernon Bryson, until recently a geneticist at the Long Island Biological Association, Cold Spring Harbor, New York, to be programme director for genetic and developmental biology in the Division of Biological and Medical Sciences; and Prof. Rogers McVaugh, on leave of absence from the University of Michigan, where he is curator of phanerogams in the University Herbarium and professor of botany, to be programme director for systematic biology in the Division of Biological and Medical Sciences.

# FLAMES AND COMBUSTION

DURING recent years the approach to combustion research has undergone a marked change from the domain of chemistry towards that of the physical sciences. This swing has been closely associated with the changing aspect of engineering requirements. The upper limit of performance of the internal combustion engine is largely set by the maximum compression ratio that can be employed without the onset of knock. Accordingly, much of the research was directed towards a better understanding of oxidation reactions in stationary systems—an essentially chemical problem. The advent of various types of jet and rocket engines, however, has emphasized the importance of heat and mass transfer in reacting flow systems, of the fundamental mechanism of flame propagation, and of the stability and structure of flame fronts. It therefore seems appropriate that, at the meeting in Bristol this year of the British Association, a series of papers on flames and combustion was included in the programme of Section A (Physics).

Dr. S. Whitehead acted as chairman of the session. The four contributions were divided equally between academic and applied research.

In general, flames can be subdivided into those which occur in the interface of the fuel and oxidant (diffusion flames), and those in which the flame front advances into a mixture of the reactants (premixed flames). In the latter case, the flame advances at a uniform velocity characteristic of the medium and can be stabilized on a burner by a suitable rate of counter-flow; in the former, the rate of burning is in general controlled by the rate of mixing. According to the flow conditions, both types of flame can be either laminar or turbulent.

The first speaker, Dr. A. G. Gaydon (Imperial College of Science and Technology, London), dealt with laminar flows in a paper entitled "The Structure of Flames". The mainly physical techniques available for the study of stabilized flames, such as measurements of temperature, spectra, ionization and others, are most effective when applied to flames of simple geometrical shape. During recent years much progress has been made in the design of special burners, and Dr. Gaydon gave a summary of the techniques now available for the stabilization of two-dimensional flame fronts both of the diffusion and of the premixed type.

The processes of heat release in the flame can be studied by the measurement of temperature distribution, by sampling and subsequent analyses, and by the study of emission and absorption spectra. The spectra, as well as indicating the presence of some short-lived chemical species, such as OH, $C_2$, CH and HCO, also give information about the energy distribution, and Dr. Gaydon discussed studies of effective translational, rotational, vibrational and electronic excitation temperatures. These are often quite abnormal in reaction zones, and similar anomalies are indicated by ionization measurements. Dr. Gaydon concluded his remarks by a brief summary of the main deductions from such measurements, with reference to the general structure of flames.

The second speaker, Dr. F. J. Weinberg (Imperial College of Science and Technology, London), discussed "The Study of Flames by Optical Means". It may perhaps seem rather incongruous that, although combustion in one of its forms was probably the first type of chemical reaction consciously put to use by man, the fundamental mechanism by which flame is propagated has still not been solved completely. The reason for this lies not only in the inherent complexity of the phenomena, but is also due, to a large extent, to the extreme conditions prevailing in combustion zones. Large temperature and composition changes occurring over extremely small intervals of space and time give rise to exceedingly large gradients of temperature and concentrations and to accelerations of the order of $10^{6}$ cm./sec.$^{-2}$. Since extrapolation of available physical and chemical data to such extreme conditions is unreliable, it is desirable to confine all studies to actual flame *in situ*, and optical methods, that is methods based on refractive index changes attendant upon combustion, constitute a most powerful tool in such studies.

After a brief outline of the underlying theory, Dr. Weinberg discussed the methods available and illustrated their use by slides. The luminous zone of a flame is not necessarily the most important nor the most informative region, and flame records using extraneous light give a more relevant, and in some cases the only reliable, account of flame events. As occasion demands, an instantaneous record or an exposure of any extended duration can be produced by photographic means, and can be used for visualization or for exact measurements. Dr. Weinberg concluded by showing examples of a complete analysis of the relevant variables across a flame front, obtained by a mathematical analysis of the distribution of deflexions produced by the flame from an initially parallel beam of light.

The more practical aspects of turbulent flames were discussed by Dr. B. P. Mullins (National Gas Turbine Establishment) in a paper entitled "Combustion and the Gas Turbine". Dr. Mullins stated that ". . . a new science, 'Combustion' has emerged in the past decade . . .". While it may perhaps seem a little premature to reject so much of the valuable earlier work, the new trend in approach, already referred to earlier in this article, has certainly become manifest during this period. Dr. Mullins, who illustrated his lecture by many spectacular demonstrations, aimed at correlating turbine combustion-chamber performance with fuel properties and other fundamental factors. The dependence of such desirable requirements as high combustion efficiency and intensity, ease of ignition and wide range of stable burning, minimum fire risk and freedom from carbon formation, on fuel properties such as calorific value, limits of inflammability, flash point, viscosity and vapour pressure, is obviously manifold and complex. Dr. Mullins outlined much valuable work aiming at making such dependence of behaviour on initial variables understood and predictable.

The last paper, by Prof. M. W. Thring and Dr. C. Hulse (University of Sheffield) and read by Dr. Hulse, dealt with "The Part played by Luminous Radiation in Furnace Heat Transfer". Luminous radiation emanates largely from soot particles which are the product of incomplete combustion in large turbulent diffusion flames. The paper dealt with parts of the work carried out by the International

Flame Radiation Committee on experimental furnaces at Ijmuiden in Holland and at Stockholm. Two types of trial are carried out. In 'performance trials' the effect of input variables on the distribution of emissivity is investigated by radiation pyrometry, while in 'combustion mechanism trials' probe methods are used to determine distributions of the more fundamental variables, such as suction pyrometer temperature, fraction of combustion, Pitot velocity and soot content. Such experiments provide much valuable information on furnace heat transfer, and general correlations are already emerging of the dependence of flame characteristics, such as flame length, temperatures and emissivities in various parts of the flame, on input variables such as nozzle design, atomizing agent, preheat temperatures and type and quantity of fuel.

Subsequent discussion reflected the diversity of the topics raised by the original contributions which may perhaps have seemed a little bewildering to the uninitiated. Such diversity, however, enables the newcomer to the field to form a balanced impression of current trends in combustion research and often gives rise to valuable cross-fertilization of ideas among workers in the various branches of the subject. In fulfilling these aims, the meeting was thoroughly successful.

F. J. WEINBERG

# ANIMAL MIGRATION

SECTION D (Zoology) of the British Association held a symposium on "Migration" in Bristol on September 2, with Mr. Peter Scott, vice-president of the Section, in the chair. A paper on "Recent Data on Movements of Desert Locust Swarms", by Dr. R. C. Rainey, Z. Waloff and H. Sayer, was read by Dr. Rainey. Recently some reasonably accurate estimates of the numbers of individuals in a locust swarm have been made by taking out samples obtained by spraying portions of the swarms with insecticides. A density of 70 locusts per square yard has been found, so that a swarm 8 square miles in area would contain some three thousand tons of locusts. These eat their own weight of food every day, and it is thus easy to understand how the recent invasion of Morocco has caused damage estimated at £4½ million.

Studies of orientation within the swarms have been made by taking photographs vertically upwards, coupled with pilot balloon observations of local wind conditions. It is found that individual locusts are orientated at random within the swarm. But this does not mean that the individual's flight is wholly independent of its neighbours'. The swarms show marked cohesion in turbulent air, and there is a strong 'edge effect' which causes locusts leaving the swarm to turn back into it. The movement of the swarm as a whole tends to be downwind, a conclusion agreeing with previous work in which the recorded tracks of locust swarms were correlated with weather charts. This downwind movement of the swarms will in the course of time inevitably lead them to the 'zones of convergence' where winds from different directions meet. The air in such zones must necessarily rise, leading to condensation, rain and moist ground conditions. The very lack of positive orientation of the swarm will thus ensure its arrival in an area which is suitable ecologically. The so-called 'intertropical fronts' are examples of such zones. Occasionally there may be a carrying-over beyond the zone in the downwind drift, as occurred last October when desert locusts appeared at several points in Britain. A film of locust swarms seen from the ground and the air was then shown.

In the discussion, Dr. Rainey said that it seems that the locusts maintain contact with one another within the swarm by visual means. Their auditory sensitivity is insufficient for this purpose. The fact that a swarm was once picked up by a ship's radar four hours after sunset cannot be cited as evidence for non-visual orientation, because the swarm was so large that there would not have been sufficient time for it to have become dispersed. While there is a possibility that the locusts appearing in England were brought by a ship, this is unlikely because of the simultaneous appearances at scattered points and the precise correlation with weather conditions. Large numbers of dead locusts were found at sea up to the latitude of Lisbon on the same day. It is impossible for locusts to keep flying actively for the thirty hours or so needed to reach England, but they can remain airborne for such periods by gliding at intervals, a habit Mr. Scott had noticed in Morocco. In 1865 substantial numbers of locusts came aboard a ship 1,200 miles off West Africa.

Mr. T. A. Stuart next spoke on "The Local Migrations of Brown Trout". He said that sea trout make local movements—the resulting concentrations being exploited by fishermen—as well as their true migrations to and from the sea. The benefit of this behaviour to the species is that far more fish can grow to maturity on the plentiful food of the sea than could if they remained in the home brook. The brown trout was originally thought to be non-migratory; but it has now been shown, by catching and marking samples of the fish, that there is a definite movement downstream to the lochs, where the fish matures. The adult fish migrates back up the streams at about the same time, though the two movements do not necessarily coincide. Occasionally precocious young males will stay and fertilize incoming females before starting on their own migration, but young females always require the extra year in the loch to lay in sufficient reserves for egg production.

The trout has a strong homing tendency, and, of many hundreds marked, none has afterwards been recovered in a stream other than that in which it was originally captured, except when the latter has been blocked. From 1952 the fry has been marked in this way, so that it is definitely known that the individual was born in a particular stream. Again strong homing tendencies have been demonstrated. Experiments have been made in which ripe fish moving up a stream are removed and released in streams on the opposite side of a large reservoir into which the streams emptied, a distance of more than a mile. No fish was recaptured in the stream to which it had been transferred; but about half those released were recovered and all save two were back in the original stream from which they had been removed. The successful homers did not only have to detect the mouth of the home stream once they were in the reservoir, but also actively to leave the foreign stream, swimming downstream against the mass of incoming fish for whom that particular stream was home. Mr. Stuart could not offer any explanation for the way in which the fish could re-orientate themselves in this manner. He thought it unlikely to be based on the detection of chemical factors, a view he maintained in the subsequent discussion when the work of Hasler was mentioned. This latter worker has claimed that fish can 'smell' the difference between streams from the difference in their organic contents.

Dr. G. V. T. Matthews then presented a review of recent work concerning "The Sun's Role in Bird Orientation". There is now plenty of evidence that birds can home from areas of which they have no previous experience. In some cases this may be due to a simple random wandering, but often the birds show initial homeward orientation followed by such swift returns that they must have flown pretty well straight home. Two types of navigation may be distinguished, the first being a limited navigation in which birds orientate themselves and fly in one direction only, fixed either by their instinctive behaviour or by a learning process. This suffices so long as the starting and finishing points always bear the same relation to one another; but the birds will be led astray if displaced in a novel direction. Secondly, there is a form of complete navigation in which the birds can orientate themselves and fly towards home no matter in which direction they were released. Many remarkable results have been obtained, culminating in the Manx shearwater that flew three thousand miles home across the Atlantic in twelve days.

The simple 'compass' navigation has been studied under laboratory conditions by making a bird indicate a certain direction. Bower birds, building their constructions with a rigidly northward orientation, provide a natural experiment, but the most important work has been done with caged migrants whose restless movements showed a strong directional component. Birds can also be trained to take up a direction by food conditioning. The prime orientating factor is undoubtedly the sun, since when it is lacking or 'displaced' by mirrors, the birds' orientation becomes random or is displaced accordingly; also, an artificial source of light is treated as if it were the true sun. The sun compass is fully developed in night migrants, and it is probable that they pick up a direction around sunset.

The complete navigation has been studied by observing the orientation behaviour of birds in the field under different conditions. Again the sun is an essential factor, only random orientation occurring in its absence. There are indications that some type of 'grid' navigation is concerned which, depending on the comparison of stimuli, becomes ineffective close to home. The main controversy is on whether the sun is still only concerned as a compass, or whether the bird can interpret the sun's position in the sky sufficiently to provide the 'grid'. This would require observation of the sun's movement along its arc, extrapolation of that movement, accurate angular measurements and an accurate internal chronometer. These are difficult to credit, but are theoretically within the capacity of the birds' sensory equipment. Some experiments aimed at confusing such a navigating mechanism have produced results supporting the hypothesis, which is the most promising one at the moment, though it cannot be finally accepted as yet. A film of the homing experiments with Manx shearwaters was then shown.

An extended discussion followed in which the required sensitivity of the bird eye, the stability of the head in flight and the accuracy of the internal chronometer received attention. Dr. Matthews said that claims of orientation within ten seconds of release could probably be referred to directional tendencies and not to position-fixing. Dr. J. Verwey, from Holland, a distinguished foreign guest at the meeting, contributed much to the discussion; he directed attention to recent work by Sauer which apparently shows that caged migrants can pick up a direction from the (unclouded) night sky, and gave an account of the orientation of sand-hoppers.

# INFORMATION THEORY

## THIRD LONDON SYMPOSIUM

THE mathematical theory of information has undergone considerable broadening and clarification during the past few years, and it is being studied, and applied to the design of experiments, by people in very varied fields—in particular, communication engineering, taxonomy, linguistics and neurophysiology. Two symposia have previously been held in London, in 1950 (*Nature*, 167, 20; 1951) and in 1952 (*Nature*, 170, 1051; 1952); and, as a further experiment, another inter-disciplinary and international meeting was held at the Royal Institution during September 12–16 last. This meeting was attended by two hundred and fifty representatives from fifteen different countries, including a large body from the United States and representatives of the Academy of Sciences of the U.S.S.R. The meeting was organized by Dr. Colin Cherry, of the Electrical Engineering Department, Imperial College of Science and Technology, London.

The symposium was opened by Prof. Balth van der Pol, of Geneva. From the start, the discussions were numerous and lively, showing that, in spite of their variety of background, the participants enjoyed a considerable degree of mutual understanding through their common study of information theory. The subject is, of course, mathematical and forms a part of scientific method; it does not relate solely to telecommunications (whence it arose) but concerns all phenomena which are 'communicative' in nature, for which representations or scientific models are made, and to which true measures can be applied, precisely and numerically. The early promise offered, that information theory would provide a valuable unifying force between various specializations, is certainly being fulfilled.

The first day of the meeting was devoted to a review of the fundamental concepts and the various measures which may be applied to 'information rates'. Prof. J. L. van Soest, of the Netherlands, discussed the essentially discrete, or quantal, nature of communicable information and some of its consequences for the theory. A paper by Mr. G. Spencer Brown on the difficulties underlying definition of 'randomness' raised discussion to the level of debate —as might be expected of that thorny subject. But the concepts of 'randomness' of a stochastic source and of the degree of 'disorder' of finite sequence are of great importance to the whole theory; information theory may yet resolve some of the difficulties.

On the same day, Dr. D. Gabor, and also Dr. W. Meyer-Eppler (Germany), extended the application of the theory to physics; in particular, to optics. Finally, the relevance of 'information' in the theory of games was considered by Dr. R. Farquharson (Great Britain).

On the second day, questions of 'coding' of information-sources were discussed—the transformations of message representations from one form to another—and of the possibility of improving rates of flow of information in noisy channels. Profs. A. E. Laemmel and P. Elias (United States) considered the theoretical bases of encoding so as to reduce the probability of error in, respectively, low and high noise-levels. Their colleague, Dr. D. A. Huffman, then showed ways in which such encodings might be carried out automatically, in practice.

A related field of work was surveyed, in the afternoon, which included study of preferred ways of cataloguing, filing or classifying data in, for example, libraries—the theory of 'clerical operations'. Mr. R. A. Fairthorne (Great Britain) has worked in close association with Dr. Calvin N. Mooers, of the United States, and gave a most humorous exposition of what a layman might otherwise guess to be a dry subject.

Real-life, human, language was the topic on the third day, with accounts of some of the remarkable statistical facts about it. Prof. W. Fucks, of Aachen, disclosed statistical data relating to nine different languages, ancient and modern, Eastern and Western, showing that they have certain forms in common. Prof. Fucks is well known for his claims to establish the authenticity of certain controversial classical texts by the use of statistical discriminating-functions applied to the words. Prof. A. S. C. Ross and Dr. D. A. Bell, of Birmingham, continued their earlier work (reported in the 1952 Symposium) of computing the degree of redundancy in a written language; this time they chose written Welsh, because it is essentially a phonetic writing, and so their results bear at least some reasonable approximation to a spoken language (statistical data about spoken languages being extremely difficult to gather). Dr. B. Mandelbrot (Geneva and Grenoble) continued the discussion to the statistical laws which relate to languages. There are close relations between statistical laws of language and other biological laws, in particular those first exposed by J. C. Willis. The reasons for the similarity are by no means clear, but the suggestion was offered, by Dr. Margaret Meade, that it arises from the fact that the various descriptive categories (phonemes, say, in language, and species or genera in biology) are set up by groups of people, in society. The laws may not be so much properties of 'nature', but of ourselves who set up descriptions and classifications.

The afternoon of this same day was devoted to "Mechanical Translation", the principal contributors being Drs. A. D. Booth and J. Cleave, of Birkbeck College, London, Prof. V. H. Yngve, of the Massachusetts Institute of Technology, and Profs. S. Ceccato and E. Maretti, from Italy. Distinction between translation and transcription (or encoding) was quickly drawn, and discussion largely concentrated upon the parts played by the syntactic and semantic rules in translation. The machines, as at present constructed, operate necessarily upon syntactic rules, and it is indeed surprising the extent to which successful conversions of a text from one language to another may be accomplished, even on a word-by-word conversion basis. The speakers emphasized the practical achievements of their work, with examples of translation of scientific texts. The semantic rules may come in with the pre- and post-editing processes, using reasonably intelligent human beings. As might be expected, it is scientific texts which offer most promise, being to a large extent inter-cultural. The two Italian speakers gave a brief account of the approach of their operational school to problems of language and translation, leading to discussion of some of the philosophical difficulties and pitfalls.

During the afternoon, speakers from Britain, France and the United States outlined modern views upon the structure of physical speech signals, and upon aural and visual perception.

The final day was devoted to psychological and neurophysiological studies. 'Models' representing certain aspects of brain functioning were discussed which, in their main attributes, are nowadays far removed from the digital computer analogies which so plagued us a few years ago. The stress to-day is upon self-organizing models, in initial random connexion. A paper by W. K. Taylor (of University College, London) is likely to become a classic; Taylor considers the properties essential to the elements of a mechanism which can 'learn by association', based upon known properties of neurons in living nerve cells and sense receptors—correct firing-rates, mutual interaction, facilitation and inhibition, accommodation—which determine the whole pattern of activity when associated. His analogue mechanisms are of the self-organizing type which, experimentally, exhibit primitive learning and adaptive behaviour.

Later in the same day, some varied uses of information theory were demonstrated in human behaviour studies, especially to give quantitative measures for experiments upon learning, motor skills, visual recognition and human operator capacity.

It was a happy sign of the times to hear, finally, a short report upon information theory developments in the U.S.S.R. from Prof. V. Siforov, the leader of the Russian delegation. He brought news of a number of well-known workers in the field, including the pioneers, Profs. A. Khinchin and A. Kolmogorov.

The Proceedings of this third London Symposium on Information Theory are to be published by Butterworths Scientific Publications, London.

COLIN CHERRY

---

# CHOLESTEROL AND FAT METABOLISM

A SYMPOSIUM on "Cholesterol and Fat Metabolism in Relation to Diet and Disease", arranged by the Scottish Group of the Nutrition Society jointly with the Biochemical Society, was held in Aberdeen on September 17. At an excellently attended meeting five papers were given as a basis of discussion, the speakers each making their characteristic contribution to the subject in hand. The subject-matter, covering the factors of diet and disease, proved attractive to biochemists, nutritionists and clinicians; and indeed the papers were so arranged that the more purely scientific aspects of the subject were followed by those parts of the problem of cholesterol and fat metabolism which are of more particular interest to pathologists and clinicians.

The subject, from the chemistry of the sterols to the treatment of atherosclerosis, is as full of interest as it is of difficulties, both in the investigation of the scientific problems and the interpretation of the complex of signs and symptoms which present themselves to the clinician.

Dr. R. P. Cook, of the Department of Biochemistry, Queen's College, Dundee, opened with a paper on "Chemistry and Biochemistry of the Sterols with Special Reference to Cholesterol". After a brief but interesting reference to the historical development of our knowledge of cholesterol, he reviewed the structure of the sterols. He discussed fully the biological function of the sterols and concluded with an account of sterol absorption in various types of animals.

Dr. J. A. Lovern, of the Torry Research Station, Aberdeen, followed with a paper on "Methods of Investigating Cholesterol and Associated Lipids". The paper dealt with the general principles involved in the main sequence of operations in a study of the lipids of a tissue, with particular emphasis on cholesterol and its esters. In an excellent and highly technical account, he indicated the extraction difficulties associated with lipid protein complex formation and pointed out that they are not likely to be serious with cholesterol, and that a rigorous removal of non-lipid impurities is not essential if the investigation is concerned solely with cholesterol; but it was shown that separation problems are serious if the fatty acids of the cholesterol esters are to be examined. Detailed reference was made to the well-known drawbacks of the Liebermann–Burchard colorimetric method for cholesterol, these being associated with the transient nature of the colour and its sensitivity to experimental conditions. Such difficulties as arise, however, can be avoided by the use of alternative reactions. It was shown how metabolic studies with precursors labelled with deuterium and radioactive carbon have thrown much light on cholesterol synthesis and metabolism in the animal.

Of importance to those interested in the origins of the secretion of the adrenal glands were the remarks of Dr. G. S. Boyd, of the Department of Biochemistry, University of Edinburgh, when he spoke on "Some Aspects of Cholesterol Metabolism". Isotopic studies have shown how acetate must be involved in the *total* synthesis of the cholesterol molecule. He emphasized how true it is that while the adrenal cortex and the liver, particularly the latter, play an important part in the synthesis of this sterol, nevertheless other tissues such as the lungs, kidneys and spleen may in some species enter the field of biosynthesis. That the adult brain, rich in cholesterol, seems to be a non-participant in this biosynthesis does not indicate that the central nervous system has no part to play in the maze of activities which apparently have their origin in cholesterol or its precursors. It was apparent that we have only to think of the influence of the various steroids and steroid hormones on the hormonal activity of the anterior lobe of the pituitary gland, with its close links with the hypothalamic nuclei, to realize the complexities of the problem. A stimulated pituitary has a potent action in depleting cholesterol sources, especially in the adrenal cortex, and in forcing the production of cortical steroids and concurrently removing, from the circulating blood, cholesterol and especially cholesterol esters for the purpose of the restoration of depleted reserves. The complexities of the subject were further emphasized by Dr. Boyd in his remarks concerning liver glycogen and blood-sugar levels and the influence which they exert through the hypothalamus on the energy balance within the body.

The last two papers, given by Dr. L. Rannie, of the Department of Pathology, King's College, Newcastle upon Tyne, on "Experimental Cholesterol Atherosclerosis", and by Prof. H. W. Fullerton, Department of Medicine, University of Aberdeen, on "The Relationship of Lipæmia to Thrombosis and Atheroma", presented the problem of cholesterol and fat metabolism in its relation to disease. To the biochemist and the nutritionist, this aspect of the problem is apparently not without interest; nevertheless, to the pathologist and more especially to the physician, with the care of the patient his supreme responsibility, it is of vital importance. In his references to experimental atherosclerosis Dr. Boyd, by a most illuminating series of slides, showed how lipid-bearing phagocytes or cholesterol taken up by reticulo-endothelial cells may become imbedded in the wall of the artery and, in this connexion, referred to the important part played by the permeability of the vessel endothelium and how at sites of turbulent flow macromolecular substances can stick to and damage the endothelial lining of the vessel. It was further made abundantly clear that the problem is made the more difficult because of species differences, and that as a result of this, one has to be extremely careful in arriving at conclusions to note the type of animal from which results have been gleaned.

Prof. Fullerton, in discussing the more clinical aspects of the problem, gave it as his opinion that while a thrombosis or fibrin deposit is situated within the wall covered by endothelium, the initial abnormalities, at least in man, are to be found in the plasma and not in the wall of the artery. Prof. Fullerton corroborated the suggestion first put forward by Prof. Duguid that the factor responsible for intermittent fibrin formation is the ingestion of meals rich in fat. As a result of his own work, he showed that the amount of fat ingested at a meal may on many occasions exceed the critical level at which an increase in the coagulability of the blood occurs.

A matter which received a certain amount of attention was the relation of plasma cholesterol to the nature of the plasma lipoproteins, and the distribution of cholesterol between the α- and the larger β-lipoproteins. As a result of discussion, it became clear that an increase in plasma cholesterol, while it may lead to an accumulation in the plasma of abnormal lipoproteins of macro-molecular structure, does not provide an explanation of the processes upon which the development of the thrombic lesion within the arterial wall depends.

Sir Rudolph Peters, of the Institute of Animal Physiology, Babraham, Cambridge, took the chair during the first part of the meeting.

# YOUNG MANAGERS IN THE UNITED STATES

During the academic years 1951–52 and 1952–53, funds were provided by the United States Government through the Mutual Security Agency for a study to be made of "the philosophy, principles and techniques of American business management" by a number of young managers from Britain. In each of the two years two groups travelled to the United States, attending the Universities of Cincinnati and Syracuse, respectively. Each course lasted for a period of nine months and the total number taking part in all the courses was sixty-three.

The young managers who carried out these studies are back at work in British industry. They have now published the outstanding impressions of the period that they spent in the United States, a summary of experience based not only upon courses of instruction but upon an overall total of 452 visits made to companies, trades unions, business associations and government departments ("Reporting Back". (Management Publications, Ltd.) 7*s.* 6*d.*).

The greater part of the book is devoted to chapters on production, distribution, finance and labour, in which the managers discuss the techniques and methods that they saw in operation. The majority of these techniques have been common practice in progressive companies in Britain for a number of years. What emerges most clearly, however, is the strong impression left in the minds of managers of this level of the general attitude towards business in the United States—an attitude more important and more fundamental than the specific techniques in which it is manifested. The report directs attention to the high social prestige attached to business in the United States, to the all-pervading competitive spirit and the ready adaptability to new methods. Stress is laid in particular on the extent to which production, prices and employment are governed by the volume of sales with a resultant cost-consciousness in every department and at all levels.

A final chapter indicates the scope of American education and training for management with its strong emphasis on the case study method and a close co-operation between the universities and industry.

## ECOLOGY OF ARID ZONES

In a recent Unesco publication*, a comprehensive list of papers on the plant ecology of arid zones is reviewed as a preliminary to further action of a practical nature.

At the second session of the Unesco's Advisory Committee for Arid Zone Research, held in Paris in September 1951, it was recommended that a commission of experts should be invited to prepare reports reviewing research on plant ecology pertaining to arid and semi-arid regions. The aim was an effective review of existing literature together with such information as Unesco might be able to collect. It was also recommended that the reports should cover ten specified regions, and that particular attention should be paid to wild plant species growing in the arid regions which might be suitable as agricultural crops. The present full and informative report is the outcome of these recommendations.

In the introduction, it is pointed out that, in view of the large part of the earth's surface that is arid, or semi-arid, there is a responsibility to make the best use of such areas, even though the major agricultural effort must necessarily, and rightly, be devoted to the more favourable climatic zones. It is held that, through the mediation of an international organization, it should be possible to examine the relevant problems of these areas on a much wider basis than can be hoped for at national centres, the more so as some of these may be working with limited resources. In undertaking this task, in consultation with other United Nations agencies, the first objective in the programme as envisaged by Unesco is the collection, sorting and use of existing information; the second is to encourage new investigations and close co-operation between research centres.

In the present volume, the résumés, discussions and bibliography, prepared by different workers, relate to investigations into the plant ecology of the arid zones of Afghanistan, India, Pakistan, Iran Israel and Turkey, Australia, Latin America, Iraq, Jordan and neighbouring territories, Egypt and neighbouring territories, Angola and South African territories, North-west Africa, United States and Canada, and tropical East Africa. In many of the reports, reference is made to the degradation of arid zone lands as a result of human intervention, particularly over-grazing and the removal of forest cover. This is strongly evidenced in the older settled areas, but is by no means confined to them. A full and accurate knowledge of the environment in any given area is needed in order to ensure a sound programme of plant introduction. This has been illustrated in practice by several notable examples in recent years. How much remains to be done in the matter of direct botanical and ecological observation emerges from the several regional reports. What can be achieved in practical agriculture, on an economic basis, remains to be seen; but some important beginnings have been made.

In that it makes readily available a fund of important information, this publication should not only be of interest to the professional botanist, ecologist and agriculturist, but also to the more general reader and, in particular, to all who are concerned with the amelioration of arid zones.

## ANIMAL ENDURANCE

An extraordinary case of bone repair and animal endurance is reported from the Dominion Museum of New Zealand (*New Zealand Sci. Rev.*, 13; March–April 1955). The shaft of the left femur of a red deer (*Cervus elaphus*) had been fractured towards the middle and the lower portion of the bone displaced farther to the left, at the same time 'telescoping' upwards, so that the two portions lay somewhat parallel to each other. In this position the two fragments were secured by the formation of two densely ossified 'bridges'. The remains of a bullet were found lodged in the bone just above the internal condyle. The impact of the bullet not only fractured the shaft of the femur towards the middle, but also the internal and external condyles. In time, ossification of the condyloid fragments cemented together the pieces, leaving deep furrows in the articular surfaces. The two 'bridges' spanning the separated portions of the shaft appear to have been built up by calluses forming over the fragments bridging the gap between the two portions of the femur and finally fusing with the separated portions of the shaft itself.

At the lower end of the upper fragment of the shaft, the medullary canal has remained open, and a certain amount of ossification taken place. The opening of the medullary canal of the lower portion of the shaft is almost completely closed, except for minute openings, by the formation of the upper 'bridge'. There is no evidence to indicate whether the animal was afterwards shot, or whether the bone was picked up after the death of the beast. It is evident, however, that the animal managed to survive for a very considerable time after it received the original injury, perhaps many months, if not several years.

The absence of predators in the country undoubtedly contributed to the survival of such a wounded animal.

# PHOTOMAGNETISM OF TRIPLET STATES OF ORGANIC MOLECULES

By Dr. D. F. EVANS
Physical Chemistry Laboratory, Oxford

It has been generally accepted since the classic work of Lewis and his collaborators[1] that the upper state responsible for the phosphorescence of many organic molecules in rigid solvents is the triplet state. The most important piece of experimental evidence was the photomagnetism observed by Lewis, Calvin and Kasha[2] during intense irradiation of fluorescein in a boric acid glass. No further results have been reported, but certain difficulties of the triplet-state hypothesis have recently been pointed out by Porter[3]. Accordingly, measurements have been made of the photomagnetism of fluorescein, 1-hydroxy-2-naphthoic acid and triphenylene (9 : 10-benzphenanthrene), which confirm and extend the earlier work.

In their experiments, Lewis *et al.* determined the absolute paramagnetic susceptibility of the triplet state of fluorescein, and found reasonable agreement with the theoretical value. The measured susceptibility depended, however, on an estimation of the stationary concentration of the triplet state, which seems very uncertain, and has not been attempted in the present work. Instead, the decay of the photomagnetism was compared with that of the phosphorescence in the case of triphenylene, which has an exceptionally long phosphorescence lifetime[4]. Since only a very small effect was obtained by Lewis *et al.*, a much more sensitive design of apparatus (Fig. 1) was used, which is an adaptation of the gas susceptibility balance described by Bitter[5].

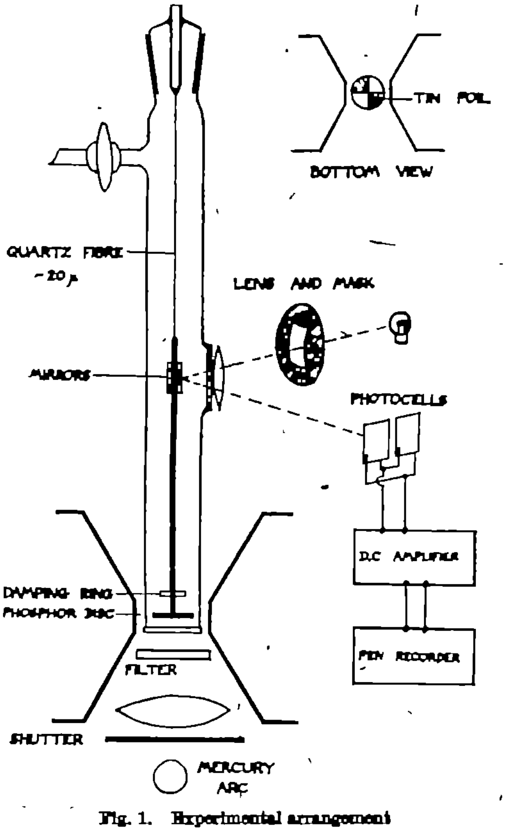

Fig. 1. Experimental arrangement

The boric acid phosphor, in the form of a thin disk (1 cm. in diameter, about 0·3–0·4 mm. thick) with alternate quadrants covered with tin foil, is suspended as shown in an atmosphere of hydrogen gas[5]. The inhomogeneous magnetic field is produced by an electromagnet run off the d.c. mains; the voltage is stabilized when necessary by 'backing off' against lead accumulators. When the disk is illuminated, a steady concentration of paramagnetic triplet molecules will be formed in the uncovered segments, and the disk will be deflected in a clockwise direction. The system, which has an undamped period of about 3 sec., is damped by the small ring of copper foil. The movement of the reflected spot of light is detected and amplified by two selenium photocells wired in series-opposition, which are connected to a push-pull d.c. amplifier and a recording milliammeter. (This arrangement has adequate sensitivity, and is simpler than one using photo-emissive cells.) In this way a continuous record of the susceptibility of the illuminated portions of the disk is obtained. Changes in susceptibility of about 0·001 per cent could be detected, corresponding to less than $10^{-10}$ mole of triplet; and it is probable that by more careful balancing of the suspension, considerably higher sensitivities could be obtained.

The samples were made by heating 0·05–0·4 parts of the organic compound with 100 parts of 'Analar' boric acid at 240° C. until most of the water was expelled[6]. The melt was pressed between two hot glass plates coated with silicone oil, and, after cooling, the thin sheet was cut into disks by gentle pressure from a sharp cork borer. The phosphors of fluorescein and 1-hydroxy-2-naphthoic acid were irradiated by light from a 500-W. Osram compact-source mercury arc. A glass condensing lens focused an image of this source on the disk, and a solution of copper nitrate or copper sulphate was used as a heat filter. It was shown with the aid of suitable filters that the wavelength of the radiation producing the photomagnetism was mainly 4360 A. and 3650 A. respectively. This was expected from the absorption spectra of the organic compounds in boric acid glass. Since triphenylene does not absorb appreciably at 3650 A., a 125-W. high-pressure mercury arc was used with a quartz condensing lens, a nickel nitrate heat filter, and (usually) a glass filter to cut off radiation of wave-lengths shorter than about 2800 A. (It has been stated[6] that boric acid glasses show intense absorption below 3100 A.; pure boric acid glasses have been prepared, however, which were reasonably transparent down to at least 2100 A.) The intensity was much less than for fluorescein and 1-hydroxy-2-naphthoic acid, but this was partly compensated by the much longer lifetime of the triphenylene triplet state, which favours a high concentration of triplet[7].

Appreciable photomagnetic effects were found in all three cases. Successive deflexions agreed within about ±2 per cent for fluorescein and 1-hydroxy-2-naphthoic acid, and a trace obtained with the latter compound is shown in Fig. 2. No deflexions were observed on exposure to light in the absence of a magnetic field. Triphenylene showed rapid photodecomposition with the formation of a blue compound. Despite this, reproducible traces could be

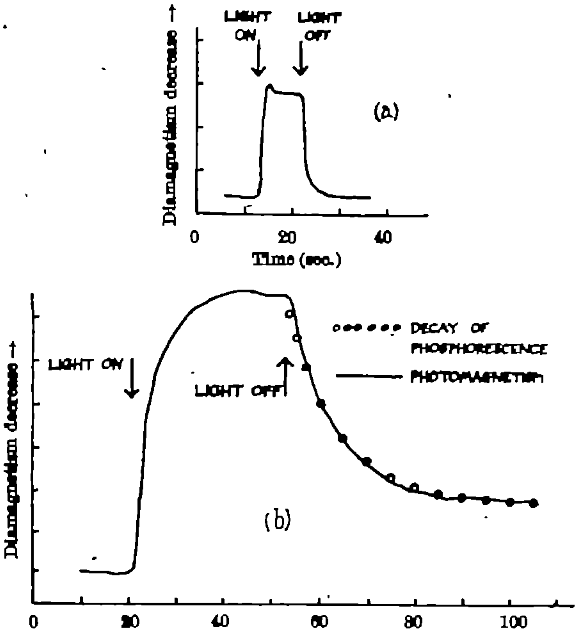

Fig. 2. Photomagnetism in (*a*) 1-hydroxy-2-naphthoic acid and (*b*) triphenylene at room temperature. The overall sensitivity was considerably higher in the latter case. The decay of phosphorescence for triphenylene is also shown, and follows accurately the expression $I = I_0 \exp(-t/11{\cdot}5)$

obtained, although successive deflexions tended to decrease in magnitude owing to competitive absorption of the exciting light. In addition, permanent deflexions were usually obtained, possibly due to permanent formation of free radicals. However, the slow rise and decay of the photomagnetism can clearly be seen in a typical trace shown in Fig. 2. After about the first two seconds the decay becomes closely exponential, with a mean lifetime of approximately 10·8 sec. The mean lifetime of the brilliant blue phosphorescence was found to be 11·5 sec. by direct measurement on the same batch of boric acid glass, using a selenium photocell and the recording system described above. These two values are in satisfactory agreement, and there can be little doubt that the same paramagnetic species is responsible for both the photomagnetism and the phosphorescence in triphenylene, and presumably also in fluorescein and 1-hydroxy-2-naphthoic acid.

It is clear from the exponential decay of both the photomagnetism and the phosphorescence that this paramagnetic species is in fact a triplet state, and not a pair of free radicals, or a free radical and an electron which slowly recombine. The recombination of a free radical and an electron after the irradiatio of certain organic compounds in glasses at lo temperatures has been studied experimentally, an found to differ very markedly from the norma phosphorescence phenomena[8]. In particular, th rate of decay of the luminescence $I$ follows a law o the type $I = I_0/t^m$, where $m$ is of the order of one.

Porter[3] has recently emphasized that in spite o the apparent general similarity between the radiationless transition from the first excited singlet to the lower triplet state, and the corresponding one from the triplet state to the ground state, these two processes actually differ very markedly in behaviour. The former is in general rapid (lifetime of the orde of $10^{-7}$ sec.[9]), and practically independent of the physical state of the molecule concerned, whereas the latter is usually much slower, and very dependent on the viscosity of the surrounding medium[8], becoming of negligible importance in rigid solvents.

It may be noted, however, that the triplet state is usually much closer in energy to the excited singlet than to the ground state, which should favour the necessary crossing of potential energy curves in the first case (see also ref. 1*b*). Also, symmetry considerations indicate that in general this transition from the excited singlet to the triplet should be the more rapid. Thus, for centrally symmetric aromatic molecules the ground state is even (*g*), whereas it is likely that both the excited singlet and triplet will normally be odd (*u*)[10]. For non-radiative processes *u*—*u* transitions are permitted, and *u*—*g* transitions are formally forbidden[11]. More generally, the symmetry with respect to rotation about an axis perpendicular to the plane of the molecule is likely to be the same for the excited singlet and triplet, but different for the ground state.

I thank Dr. E. J. Bowen and Dr. R. E. Richards for advice and encouragement, Prof. C. A. Coulson for a valuable discussion on the theoretical aspects, and the University of Oxford for an I.C.I. fellowship.

# AN AUXANOMETER FOR ISOLATED PLANT SECTIONS

By D. B. IDLE

Department of Botany, University of Southampton

THE auxanometer to be described is basically unspecialized, and may be adapted to record the extension/time characteristics of a variety of tissues under a number of environmental conditions. In its present form, the machine measures in darkness the progress of extension in isolated sections of the epicotyl of dark-grown broad bean seedlings when supplied with various nutrients independently at the cut ends of the section. It has also been used on the same material immersed in water, simulating current methods of bio-assay.

Fig. 1 illustrates the mechanism. The success of the method and its potential usefulness depend on the simplicity and ubiquity of the Cambridge rocking

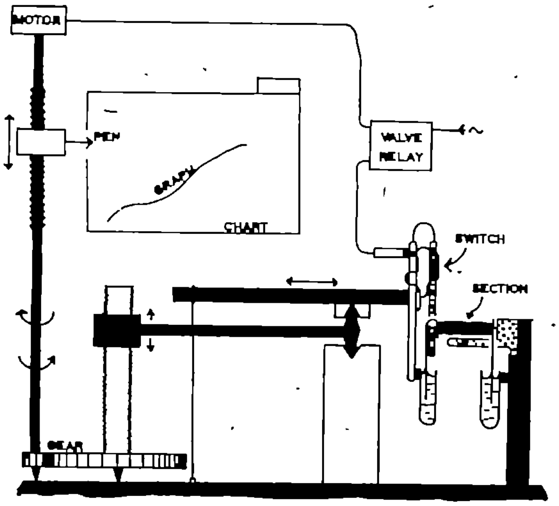

Fig. 1. The mechanism consists of a Cambridge rocking microtome driven by an Everett Edgcumbe 'Synlock' type *MRX* motor, which has two separate windings, one for each direction. The valve operates a P.O. type 3000 relay from an unsmoothed power supply. The switch controls the bias on the valve. The stippled material supporting the section is polythene, the rest of the switch being of 'Perspex'. Strips of filter paper supply the ends of the section with water from small cups holding about 1 c.c. each. The position of the chart as shown is displaced to the right

microtome. A switch is fitted to the block holder of the microtome, and is directly coupled with magnification to the recording pen. The coupling is moved in either direction by a reversible motor, the speed of which is one revolution per minute; the direction taken by the motor depends upon whether the switch is open or closed. Elongation of the section closes the switch, when the motor rotates so as to move the switch away from the section. The switch then opens, reversing the direction of rotation. As a result the switch contacts close again, and the cycle is repeated. The apparatus in fact hunts around the end of the section, the extension or contraction of which is followed by the mean position of the switch. The hunting-range is of the order of 5μ, and this will only show on the record at higher magnification than has so far been used.

The record appears as a graph of total extension against time on a chart 5 in. high, corresponding to 4 mm. extension. The graph may be converted to one of rate with time by measuring the slope with a protractor. Total extension may be measured to within about 20μ. The time-scale may be resolved to within 5 min. using a chart speed of 0·75 in. per hr. The rate of extension may be estimated to the nearest micron per minute for a minimum period of some 15 min.

The contacts of the switch are of crossed 30-gauge platinum wires, sprung such that no great change in pressure occurs as they open or close. The moving arm of the switch is spring-loaded so that the plant section is under a constant pressure of the order of 1 gm. This keeps the cut ends in comfortable contact with the filter-paper strips conducting moisture to the section.

Some typical results are shown in Fig. 2. The fluctuations in the rate of extension during the first five hours are characteristic responses to cutting, and are found in both isolated sections of stem and in lengths of stem without roots and seed but retaining the apical meristem; this is known from a previous unpublished investigation.

It has been found that if the sections are wholly or partially immersed in water, the pattern of growth normal to the tissue is lost. Under these conditions, there is an initial period of rapid extension lasting for about an hour, followed by a long phase of fairly constant rate lasting for perhaps 20 hr. However, the mode of support of the section shown in Fig. 1 was found to give results more like those previously observed in intact plants. There is a conspicuous response to handling followed by a period of decreasing rate of extension, there being little extension after about 15 hr. In the case of added auxin, the second phase is longer.

It may be noted that the graph of rate of extension has always been found to be more eloquent than the curve plotted by the machine. This total-extension/time curve does not easily indicate to the eye changes in the rate of extension that may be very significant indications of metabolic activity. Such changes usually occupy an hour or two, and are easily lost when resolution is of a comparable period, as is usual in most methods of bio-assay. Similarly, inspection of the rate/time records of individual sections often reveals meaningful phases of rate of extension that may not be exactly synchronous in all cases. Were such records to be averaged before inspection, the sequence of events in fact common to all the records would become partially or wholly obliterated. Methods of bio-assay using stem sections have in the past involved average measurements taken at quite infrequent intervals of time; as a result, the

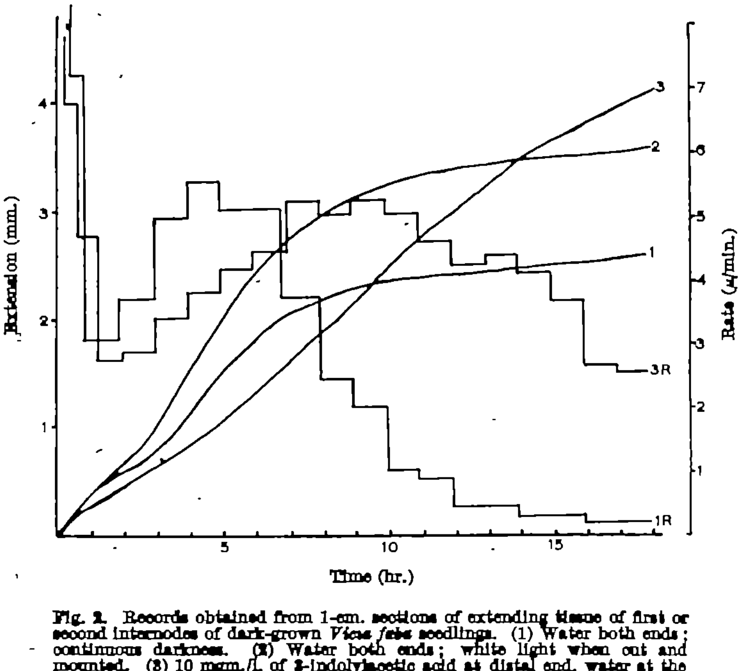

Fig. 2. Records obtained from 1-cm. sections of extending tissue of first or second internodes of dark-grown *Vicia faba* seedlings. (1) Water both ends; continuous darkness. (2) Water both ends; white light when cut and mounted. (3) 10 mgm./l. of 3-indolylacetic acid at distal end, water at the other; cut and mounted in darkness. (1*R*) and (3*R*) Curves 1 and 3 plotted as rate of extension with time

peculiarities of the initial rate of extension have not been observed or studied. Even the few observations as yet completed suggest that these initial phases are of great interest and importance, and they fully support the statements of Bennet-Clark[1] and of Audus[2].

This work has been carried out under a researc award of the Department of Scientific and Industria Research, and with the help and encouragement o Prof. W. T. Williams. [July 20

# STRUCTURE OF POLYGLYCINE II

By Dr F. H. C. CRICK
AND
Dr. ALEXANDER RICH*

Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems,
Cavendish Laboratory, Cambridge

VERY recently Bamford and his colleagues[1] have described their work on a second form of polyglycine, which they call polyglycine II. The purpose of this communication is to suggest a structure for this substance.

Bamford *et al.*[1] have shown clearly that polyglycine can give two types of X-ray diagram according to the method of precipitation. Polyglycine I gives strong reflexions at 4·4 A. and 3·45 A., and is thus some kind of β-structure; that is, the polypeptide chains are almost but not quite fully extended, and hydrogen bonds are formed between neighbouring chains (in approximately the same plane) to form sheets of parallel or anti-parallel chains. Polyglycine II, on the other hand, gives a very strong reflexion at 4·15 A., and a moderately strong one at 3·1 A. Only a powder diagram has so far been obtained. Bamford *et al.*[1] have shown that the X-ray picture cannot be easily explained in terms of any well-known configuration of the polypeptide chain.

The structure we propose is simple. All the polypeptide chains are parallel and each one has a threefold screw axis. The chains are packed in a hexagonal array, each chain being hydrogen-bonded to each of its six neighbours. These hydrogen bonds lie roughly perpendicular to the screw axis, and, as implied above, run in several directions and not merely in one direction as in a β-structure. This can be seen in Fig. 1, which is a projection of the structure looking down the screw axis.

Another view of the structure is shown in Fig. 2. This is a projection along the *x*-axis and perpendicular to the screw axis (the *z*-axis), which runs vertically. The easiest way to visualize the structure is to look at one of the residues at the bottom of the figure. This shows that the planar peptide group is inclined at about 35° to the fibre axis, and has its plane perpendicular to that of the paper. There is thus an infinite sequence of hydrogen bonds running from one cell to the next, perpendicular to the paper and joining residues of adjacent chains. It follows that the atoms of these residues all lie on an inclined lathe. There is another set of such lathes at a level 3·1 A. higher in the structure, but due to the 120° rotation of the screw axis these lathes run at an angle to the paper. At 3·1 A. higher again there is a third set of lathes, again at an angle to the paper. Above that the structure is repeated.

The formal crystallographic description of the structure is: $a = 4{\cdot}8$ A., $c = 9{\cdot}3$ A., space group $P3_1$, one residue per asymmetric unit. The calculated density is 1·54 gm./c.c.; observed density[1], 1·43 gm./c.c. (It is often found for this type of material that the calculated density is 5–10 per cent higher than the observed.) The co-ordinates of the atoms

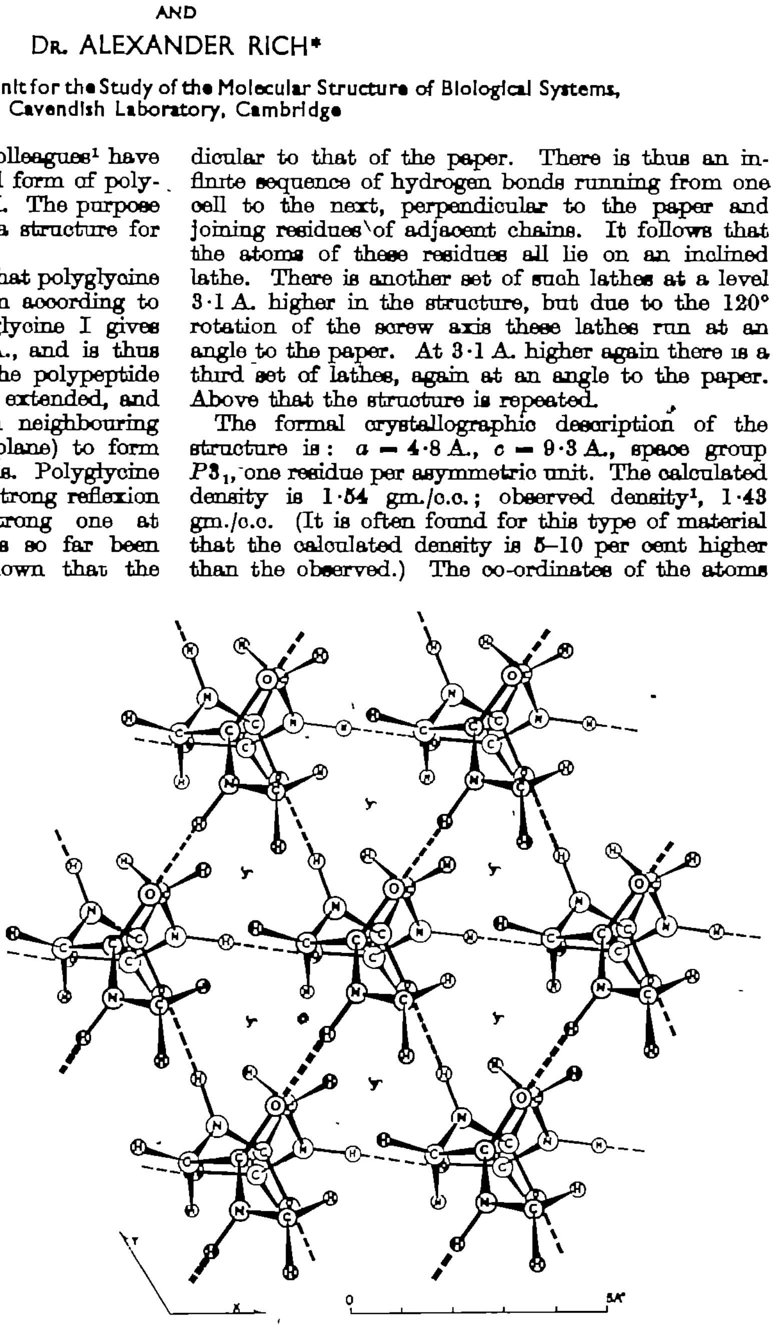

Fig. 1. A projection of the structure down the screw axis, showing seven chains. Hydrogen bonds, drawn as dashed lines, run in a number of directions linking neighbouring chains together

---

* Section on Physical Chemistry, National Institute of Mental Health, Bethesda 14, Maryland

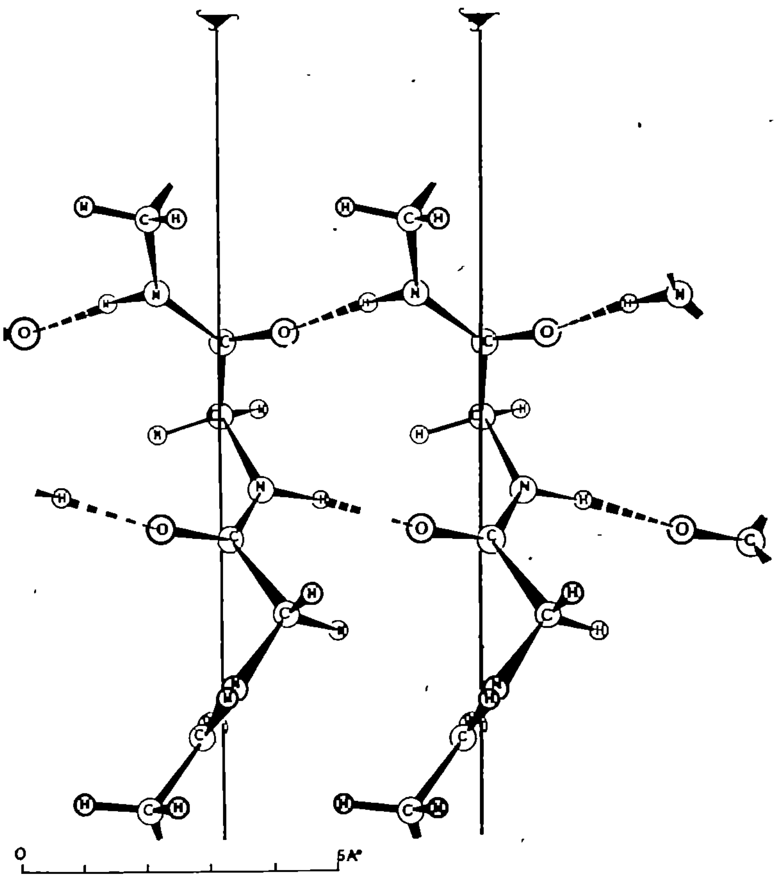

Fig. 2. A projection of the structure with the screw axis vertical. One a-axis points towards the reader; the chain on the right has been drawn as nearer to the reader than the chain on the left (see Fig. 1). Note the planar peptide groups edge-on at the bottom of the figure. The hydrogen bonds from these groups are almost perpendicular to the paper

of one asymmetric unit (excepting hydrogen atoms) are given in Table 1, to the nearest 0·05 A.

In building the structure we have adopted the standard Pauling–Corey[2] bond-distances and angles. The hydrogen bond-distance (nitrogen to oxygen) is 2·76 A., which is a little short, but quite acceptable[3]. The hydrogen bond is almost straight, as can be seen from the figures. All the van der Waals distances are acceptable, and in fact space-filling models show that the chains pack together in a comfortable manner.

Since there is no asymmetric carbon atom in polyglycine, the mirror image structure (space group $P3_1$) is equally possible.

We have calculated the spacings and intensities expected from this structure for all reflexions out to 1·8 A. Dr. C. H. Bamford and his colleagues have kindly shown us the original of the powder photograph (their Fig. 1). Their X-ray data are in good qualitative agreement with our calculations. The very strong 4·15 A. reflexion is $10\bar{1}0$. A glance at Fig. 1 shows that this will be intense. The 3·1-A. reflexion has a small contribution from 0003, but is mostly due to $10\bar{1}2$, spacing 3·09 A. The strength of this reflexion is mainly produced by the inclined planes of the peptide groups which make up the lathes described above.

We thus feel confident that polyglycine II has the structure we have described, or a closely similar structure. It should be realized, however, that there is a family of possible structures of this general type. All these would have in common polypeptide backbones with three-fold screw axes and a repeat of about 9·3 A. There are only two possible ways of achieving this backbone: the one we have described, and an analogous one in which the nitrogen atom is close to the fibre axis. Such chains can have either right-handed screws, or left-handed, and can be combined in various ways, either parallel or anti-parallel. So far as we can see, the structure we have described is the simplest member of the family. Stimulated by a suggestion by Dr. A. Elliott, we have found that it is possible to remove a chain from the structure and then replace it running in the opposite direction. All the hydrogen bonds can be remade and at first glance the modified structure looks very similar to the original, so that its X-ray diffraction pattern will also be similar. Only a very detailed study of the experimental results will enable one to say whether the simple structure is strictly correct, or only a first approximation.

Whatever the outcome of such studies, we feel that the present qualitative agreement with the experimental evidence makes it almost certain that the structure of polyglycine II is of this general type. This enables us to conclude that only polyglycine can form such a lattice—there is no room for side-chains in the lattice unless some of the hydrogen bonds are broken.

We see no special reason why a single polyglycine chain should take up this precise configuration; this is presumably dictated by the interaction between neighbouring chains, which imposes the exact three-fold screw axis. We note with interest that polyproline, the structure of which has recently been reported by Cowan and McGavin[4], and which is unable to form hydrogen bonds, takes up a similar backbone configuration.

As yet it has not been possible to obtain[1] a fibre diagram of polyglycine II. This is probably because any process used to produce orientation will tend to stretch the structure, and it will then pass over to the more extended β-form of polyglycine I.

We should like to thank Dr. Bamford and his colleagues both for showing us their X-ray photographs and for helpful discussion. [Sept. 20

## Occurrence of Attenuated Strains of Myxoma Virus in Europe

Several slightly attenuated strains of myxoma virus have been recovered from the field in Australia[1]; indeed, it is now rather uncommon to recover strains having the same high virulence as the material used for initiating the epizootics, and for the subsequent inoculation campaigns. The position in Europe, however, appears to have been different. European investigators[2] have been unanimous in their observations that there has been no fall in the virulence of the virus since it was introduced into wild rabbits in France in June 1952. Experiments made in Canberra with several European field-strains have confirmed this view. Very recently, however, we have obtained evidence of attenuation of the virus in the field in Europe.

Our standard technique for the comparison of the virulence of myxoma strains consists of the intradermal inoculation of five 4-months-old laboratory rabbits with 0·1 ml. of saline containing about five rabbit-infectious doses of virus. Observations on larger groups of rabbits have shown that the survival times of the inoculated rabbits are correlated with the mortality-rates and serve as the best single criterion of virulence with these small groups of animals.

The survival times of groups of rabbits inoculated with various strains of virus obtained from naturally infected cases in Europe are shown in Table 1. The 'Lausanne' strain, kindly provided by Dr. G. Bouvier, is only a few domestic rabbit passages from the South American *Sylvilagus* rabbits, and was the strain used to initiate the epizootics in Europe (Bouvier, personal communication, 1954). The 'standard laboratory strain' is the virus used to initiate the Australian epizootics; 'neuromyxoma'[3] is the least virulent of all myxoma strains, and *KM*13 is a slightly attenuated Australian field-strain, which has been extensively studied in our laboratory and represents the level of virulence most commonly encountered in the field in Australia.

The uniform high virulence of strains from Europe up to the 'Loiret April 1955' strain is apparent, and the clinical picture of the infection caused by all these strains has been quite uniform, and distinctly different from that associated with infections by the Australian strains. Strain 'Loiret April 1955' was sent to us by Dr. H. Jacotot, of the Pasteur Institute Paris, and was obtained on April 7, 1955, from tumour material removed from a tame rabbit suffering from myxomatosis contracted naturally. It produces the large tumours characteristic of the European strains, although they develop more slowly. The strain 'Nottingham April 1955', supplied to us by Mr. J. R. Hudson, of the Veterinary Laboratory, Weybridge, England, is also attenuated. Of five rabbits inoculated with small doses of the first laboratory-rabbit passage material from a recovering wild rabbit, two died with symptoms and signs characteristic of the fully virulent European strains, one became severely ill and died thirty-four days after inoculation, and the other two suffered a relatively mild disease, although each developed large primary and secondary tumours. Experiments still in their preliminary stages suggest that limit dilution subinoculations of material taken from the severely affected rabbits produce the classical severe European type of disease, whereas similar passage of material taken from the mild cases usually produces the mild form of the disease.

Estimation of the skin titre of secondary nodules on four rabbits infected with the 'Loiret April 1955' strain ranged from $10^{8}$ to $10^{8\cdot7}$ rabbit-infectious doses per gm. of epidermal tissue twenty-five days after infection, and $10^{7}$ in one rabbit tested thirty-eight days after infection. These concentrations exceed those found in rabbits infected with Australian attenuated strains at similar intervals after infection. Similar titrations on the three rabbits which survived infection with the 'Nottingham April 1955' strain gave figures of $10^{5\cdot3}$, $10^{5\cdot6}$ and $10^{5\cdot8}$ rabbit-infectious doses per gm. on the twenty-sixth day after inoculation, which is rather lower than that usually found with Australian attenuated strains at the same stage of the disease. Consideration of the factors affecting transmission of myxomatosis (Fenner, Day and Woodroofe, in preparation) suggests that attenuated

## Myxoma Virus in Britain

IT is well known that myxomatosis has caused a high mortality among wild rabbit populations in most parts of England and Wales, and in those parts of Scotland and Ireland to which the disease has spread. Where it has been possible to make accurate observations, a mortality-rate of about 99 per cent was found. A similar death-rate was usual in Australia during the first year (1950–51) of their epizootic, but attenuated strains were found from 1953 onwards[1].

Ever since October 1953, when myxomatosis was first notified in Britain, rabbits surviving in areas through which the disease has passed have been examined for evidence of recovery. Most of these rabbits have been found not to have been exposed to infection in the wild; but a small number have been rabbits recovered from the disease, as indicated by the presence of immune bodies in their serum. From some rabbits which were apparently recovering, strains of virus have been isolated and these have proved to be of normal virulence.

Only in one part of the country, the Sherwood Forest area of Nottinghamshire, have attenuated strains of virus been found in rabbits. In this area estate workers and the Ministry's field-officers noted from April 1955 onwards the presence of an unusual number of individuals that appeared to be recovering. One of the strains isolated at Weybridge is mentioned in the preceding communication from Prof. Frank Fenner and Mr. I. D. Marshall, and a brief note on them has been published elsewhere[2]. Myxomatosis first appeared in the Sherwood Forest area in September 1954 and, in spite of a heavy concentration of rabbits and the presence of fleas, appears to have moved and to be moving very slowly. The mortality has been erratic, on some estates less than half the rabbits being killed by the disease. Serum samples from sixty-four rabbits have been examined, and in thirty-two, immune bodies have been present. Four strains of virus have been isolated which, when inoculated into domestic rabbits, produce a 'nodular' type of infection. Œdema is less diffuse than in typical cases, but the small nodules may cover extensive areas and appear anywhere on the body, although usually more numerous on the face and ears. During the earlier stages, the œdematous nodules contain typical, fully virulent virus, but later they shrink and the skin surface dries to form a scab; and although the nodules and scabs may contain a high titre of virus, it is of reduced virulence.

Recent observations have shown that myxomatosis is again moving across the area and three recent strains of virus, although not of full virulence, are more virulent than those obtained some months ago. Immune recovered rabbits will not be killed by this second wave, but it is likely that the susceptibles will again be reduced in numbers, and the situation is being watched closely.

Fully virulent virus is producing a normal, heavy mortality only a few miles to the south.

Conditions in Britain are so different from those in Australia that conclusions based on the behaviour of myxomatosis in one country will not necessarily be applicable to the other. Mosquitoes are the principal vectors of myxomatosis in Australia, and the initial spread of the disease was more explosive than in Britain, where natural spread has been by the flea and has therefore been comparatively slow[3].

It is emphasized that the attenuation of the myxoma virus in part of Sherwood Forest is an isolated case, affects only a relatively small area, and calls for an increase rather than a slackening of efforts to destroy surviving rabbits.

We are grateful to Prof. Fenner for sending us a copy of his communication before publication and for this opportunity to describe briefly the background of the strain to which he refers.

## Identification of Pseudocholinesterase in the Tissues of Ruminants

MOST animal tissues and body fluids contain two types of cholinesterase which have been designated as true cholinesterase and pseudocholinesterase in accordance with their physiological function[1]. Both enzymes are inhibited to about the same extent by low concentrations of eserine as well as of prostigmine. In order to measure the activities of the two enzymes separately in a mixture of both, Mendel *et al.*[2] used what they considered to be 'specific substrates': acetyl-β-methylcholine for the true cholinesterase and benzoylcholine for the pseudocholinesterase. Since the sera and tissues of ruminants do not exhibit appreciable eserine-sensitive activity towards benzoylcholine, it had been assumed that they do not possess any pseudocholinesterase[3]. However, it has recently been found that the spleen of the ox[4] and other tissues of ruminants[5] contain enzymes capable of hydrolysing butyrylcholine, an ester which is hydrolysed rapidly by the pseudocholinesterases of other species but not by the true cholinesterases[6].

A study of the characteristics of the cholinesterases in ox spleen has shown that approximately 90 per

Table 1. DIFFERENTIATION OF THE CHOLINESTERASES IN A SUSPENSION OF OX SPLEEN BY THE USE OF SELECTIVE INHIBITORS

| Enzyme | Substrate | $p(I\,50)$ values (– log of the molar concentration of inhibitor required to produce 50 per cent inhibition) with the following compounds | | |
|---|---|---|---|---|
| | | Diisopropyl phosphonofluoridate (ref. 9) | N,N′-Diisopropyl phosphorodiamido fluoridate (isopestox; mipafox) (ref. 10) | Dimethyl carbamate of 2-hydroxy-5-phenylbenzyl trimethyl ammonium bromide (*Ro*-2-0683) (ref. 11) |
| True cholinesterase | Acetyl-$\beta$-methyl choline | 6·5 | 4·7 | 7·0 |
| Pseudocholinesterase | Butyrylcholine | 8·5 | 7·7 | 8·0 |
| Eserine-resistant esterase | Butyrylcholine | 8·0 | <4·0 | <4·0 |

cent of the activity towards butyrylcholine (0·03 *M*) is due to a pseudocholinesterase, and the remaining 10 per cent to one of the unidentified eserine-resistant enzymes similar to those found in other species[7,8]. Approximately 45 per cent of the total activity towards acetylcholine (0·03 *M*) is due to a true cholinesterase and the remainder to a pseudocholinesterase. The activity of the latter enzyme reaches a maximum at high concentrations of acetyl- and butyrylcholine, the Michaelis constant ($K_s$) with butyrylcholine being $10^{-3}$ *M*. Table 1 indicates the concentrations of three selective pseudocholinesterase inhibitors required to produce 50 per cent inhibition of each of the three enzymes mentioned above; these results are very similar to those obtained under the same experimental conditions with the pseudocholinesterases, true cholinesterases and eserine-resistant esterases of other species[7-11]. The enzyme responsible for the major portion of the hydrolysis of butyrylcholine by ox spleen can therefore be classified as a pseudocholinesterase which does not hydrolyse benzoylcholine at an appreciable rate.

In this connexion, it might be noted that the relative activity of the pseudocholinesterases of other species towards benzoylcholine varies considerably and is very low, for example, in the case of the pseudocholinesterases from mouse and chicken[8]. Although benzoylcholine has been very useful as a specific substrate for the identification and measurement of pseudocholinesterase activity in most species, it is evident that the use of benzoylcholine for this purpose has led to incorrect conclusions[4] concerning the occurrence of pseudocholinesterase in the tissues of ruminants. These results, together with those of recent investigations[8,12], which show that butyrylcholine is hydrolysed much more rapidly than benzoylcholine by the pseudocholinesterases of many species, make it advisable to measure pseudocholinesterase activity with butyrylcholine as first advocated by Cohen *et al.*[6].

For identification of cholinesterases, however, it seems safer not to rely on the use of 'specific' substrates. None of these substrates is in fact specifically hydrolysed by one esterase only; acetyl-β-methylcholine is hydrolysed by the pseudocholinesterases of avian species[8,12,13], and both benzoyl- and butyrylcholine are hydrolysed by eserine-resistant esterases in certain cases[3,7,8]. Because of such exceptions the best method for identification of the cholinesterases appears to be the use of selective cholinesterase inhibitors in combination with the substrates acetylcholine, butyrylcholine and acetyl-β-methylcholine[8,12,13]. Of the three selective inhibitors tested in this investigation (Table 1), only two are generally applicable, since diisopropyl phosphonofluoridate also inhibits various eserine-resistant esterases[7,8].

## Site of Virus-like Particles in Rous Fowl Sarcoma Cells

A SIMPLE and reliable technique has been evolved for preparing freshly collected ascites tumour cells for electron microscopy[1]. It makes use of the fact that when such cells are incubated under appropriate conditions and are brought into contact with 'Formvar'-coated slides, they change shape within a few minutes of gaining a grip on the 'Formvar'. The

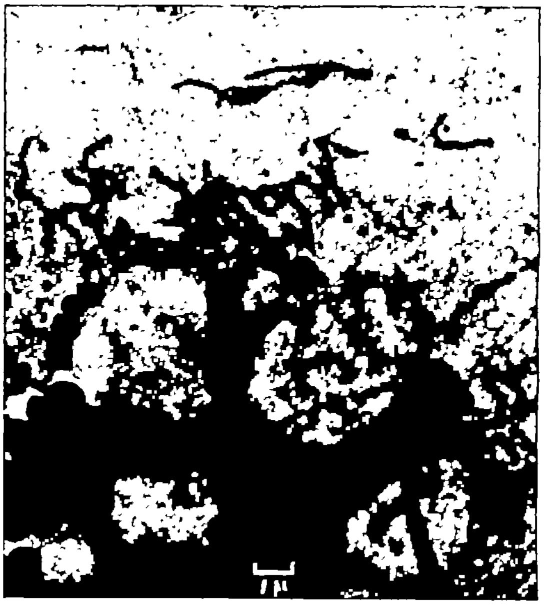

Fig. 1. Part of a thinly spread Rous ascites tumour cell. Filamentous mitochondria are scattered in the cytoplasm, which also contains the endoplasmic reticulum and osmiophilic lipoid bodies. Numerous dense virus-like particles are present in one of the vacuoles in the field. Fixation over osmium vapour was started when the cell had been *in vitro* for 17 min. and was continued for 21 hr. Electron micrograph, × 5,000

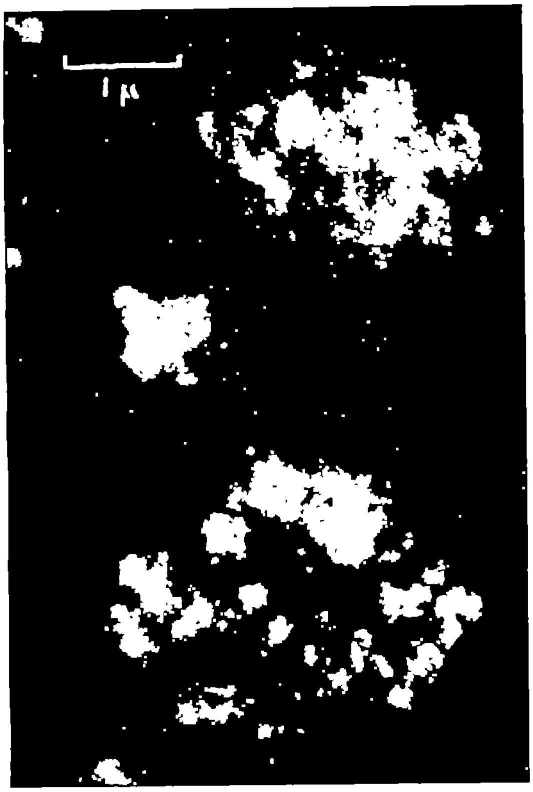

Fig. 2. Two vacuoles from another Rous ascites cell prepared as that of Fig 1, and showing the virus-like particles at higher magnification. Electron micrograph, × 15,000

change is from the round form of the free dispersed single cells to a spindle form, and an early stage in the transformation consists of the cells spreading widely and becoming extremely thin. Ascites tumour cells spread thinly in this way are very suitable for electron microscopy ; they can be fixed over osmium vapour and transferred easily to electron microscope specimen grids with samples of the 'Formvar' to which they adhere[2].

This method avoids the labour and uncertainty of the tissue culture technique for preparing cells for electron microscopy[3], allows the cells to be prepared in large numbers and makes it unnecessary to keep them for many hours in an unnatural *in vitro* environment. It has been applied to the single dispersed tumour cells of an ascites form of the Rous No. 1 fowl sarcoma[4], in which all, or at the worst almost all, the cells flatten out under the conditions used. Thus, preparations made in this way avoid the problems of sampling inherent in the examination of ultra-thin sections of Rous sarcoma material.

Some 12,000 well-preserved Rous ascites cells from seven different tumours have been examined in the electron microscope. In some of the cells from four of these tumours, virus-like particles slightly less than 0·1μ in diameter have been observed ; in the other three tumours, no cells with particles were found, although about two thousand cells were examined from each. When cells with particles have been present, their incidence has varied from tumour to tumour, ranging from less than 1 in 2,000 cells to 1 in 50 cells ; it has, however, been constant for all the preparations made from any one tumour, thus arguing against a chance artefact being responsible for the appearances in question. The particles have always been found grouped together in one or more of the vacuoles common in this type of cell (Figs. 1 and 2) and are readily seen by phase-contrast microscopy when the cells are alive. No particles have been observed free in the cytoplasm of the cells of the present series, although cytoplasmic structure is well preserved by the technique used (Fig. 1).

## Role of 5-Hydroxytryptamine in Mental Diseases and its Antagonism to Lysergic Acid Derivatives

The possibility that 5-hydroxytryptamine plays a part in abnormal mental processes has been discussed by Gaddum[1] and by Woolley and Shaw[2]. The hypothesis is based on the findings that this substance is a natural constituent of nervous tissue, particularly of the brain[3], and that certain of its actions are antagonized by lysergic acid diethylamide[4], a drug which on oral application and in doses of only 0·5–1·0 μgm./kgm. produces pronounced psychic disturbances in normal human beings[5]. According to this hypothesis, the effects of lysergic acid diethylamide result from its antagonistic effect on the 5-hydroxytryptamine in the brain.

In the course of screening derivatives of lysergic acid diethylamide for 5-hydroxytryptamine-blocking effects, we have found in 2-brom-*d*-lysergic acid diethylamide, coded *BOL* 148, a compound which, like lysergic acid diethylamide, strongly antagonizes certain effects of 5-hydroxytryptamine, but unlike lysergic acid diethylamide does not produce abnormal psychic disturbances. The introduction of one bromine atom into the molecule of lysergic acid diethylamide thus completely alters its activity ; it loses the characteristic property of producing psychic disturbances in man but retains the strong anti-5-hydroxytryptamine action.

When comparing the central and peripheral effects of lysergic acid diethylamide with those of *BOL* 148, pronounced differences were found[6]. In normal and waltzing mice, lysergic acid diethylamide causes excitation, whereas *BOL* 148 has a sedative effect. In cats, small doses of the former cause a fall in arterial blood pressure and bradycardia, whereas the latter, tested in doses up to 1 mgm./kgm., was practically inactive. Again, the former has a strong stimulating effect on the rabbit uterus *in situ*, whereas the latter is practically inactive. We have also tested *BOL* 148 on ourselves and on some of our laboratory staff. It never produced signs of mental or psychic disturbances such as we regularly observed after lysergic acid diethylamide, even when used in doses twenty times as great. There was only a certain sedative action, consisting in a feeling of general fatigue and sometimes slight nausea.

In spite of the fact that the pharmacological effects of *BOL* 148 differ so completely from those of lysergic acid diethylamide in animals as well as in humans, it was found to share with the latter the strong anti-5-hydroxytryptamine action. Erspamer[7] had shown that lysergic acid diethylamide is a strong antagonist to 5-hydroxytryptamine on the isolated rat uterus. On this preparation and on the isolated perfused kidney of the rat, *BOL* 148 was found to be an even stronger antagonist, being about one and a half times as active. In other tests *BOL* 148 was found to have approximately the same anti-5-hydroxytryptamine action as lysergic acid diethylamide, for example, in antagonizing the effects of intra-aortic injections of 5-hydroxytryptamine on the arterial blood pressure and the renal and mesenteric blood flow of the cat, in blocking the bronchoconstrictor effect of 5-hydroxytryptamine and in antagonizing its potentiating effect on barbiturates. The anti-5-hydroxytryptamine effect of *BOL* 148 is highly specific; in doses which fully antagonized the action of 5-hydroxytryptamine, *BOL* 148 showed no signs of an antihistamine, antiadrenaline or anti-acetylcholine effect.

As the hypothesis of the cerebral functions of 5-hydroxytryptamine is based to a great extent on the fact that lysergic acid diethylamide is a strong antagonist of 5-hydroxytryptamine, the present finding that *BOL* 148 is as active as lysergic acid diethylamide in antagonizing 5-hydroxytryptamine but produces none of the mental disturbances makes it necessary to reconsider this hypothesis. It cannot be argued that *BOL* 148 lacks cerebral actions because it does not penetrate into the brain tissue; the sedative action it produces is a central effect. In addition, after an injection, *BOL* 148 could be detected in the same indirect way as lysergic acid diethylamide in extracts of the brain, when tested for anti-5-hydroxytryptamine activity. Brain extracts of mice previously injected with either *BOL* 148 or lysergic acid diethylamide exerted anti-5-hydroxytryptamine activity[8].

Our results with *BOL* 148 thus make it difficult to correlate the psychic effects of lysergic acid diethylamide with its anti-5-hydroxytryptamine property. At present, we are not justified in assuming a causal relationship between these two properties of lysergic acid diethylamide, although it may eventually be found that the 5-hydroxytryptamine in the brain is involved in the central actions of lysergic acid diethylamide. The mere fact of a pharmacological antagonism between lysergic acid diethylamide and 5-hydroxytryptamine, however, no longer provides evidence for the hypothesis that inhibition of the latter in the brain is the cause of the mental disturbances.

## Transfer of Proteins from the Yolk to the Chick Embryo

THE transfer of antibodies from the mother to the fœtus in certain mammals, and from the hen to the egg yolk and thence to the embryo in birds, is wel established. Whether proteins other than antibodies are thus transferred is still open to question. Despite our lack of knowledge on this topic, it is generally thought, as Buxton[1] recently pointed out, that proteins pass from the blood or tissues of the hen as hydrolytic products which are reassembled into proteins within the ovum. Because of the proteolytic activity of the yolk sac and its contents, a similar mechanism is supposed to account for the passage of protein from the yolk into the circulation of the embryo.

We found recently[2] that, after intravenous injection into the hen, bovine γ-globulin and crystalline albumin, and whole lobster and rat sera are readily detected in the yolk by serological means. Further study of the bovine serum fractions in the yolk showed that they retained their respective electrophoretic mobilities on filter paper and could be displaced like the original proteins by ultracentrifugation. The bovine proteins deposited in the yolk do not interfere with development, since we have reared a number of the chicks to maturity and normal reproduction.

The experiments have now been extended to the passage of proteins from the yolk sac into the embryo. 0·3 or 1·0 ml. of 5 per cent solutions of Armour's bovine γ-globulin and crystalline serum albumin were injected into the yolk sacs of chick embryos varying in age from three to nineteen incubation days. Embryos older than six days were bled from the vitelline or allantoic arteries after various intervals of time; younger embryos were extracted *in toto* with 0·9 per cent saline. Rabbit antisera previously shown not to react in precipitin tests with rat, human and embryonic and adult chicken sera were used to detect bovine protein activity in the embryonic sera and body extracts. Fig. 1 shows the results obtained with γ-globulin. Fewer experiments have been done with albumin, but positive tests at consistently lower titres have been obtained.

Bovine γ-globulin was not detectable in sera or extracts prior to eight days of incubation. In the period between ten and fifteen days incubation, both

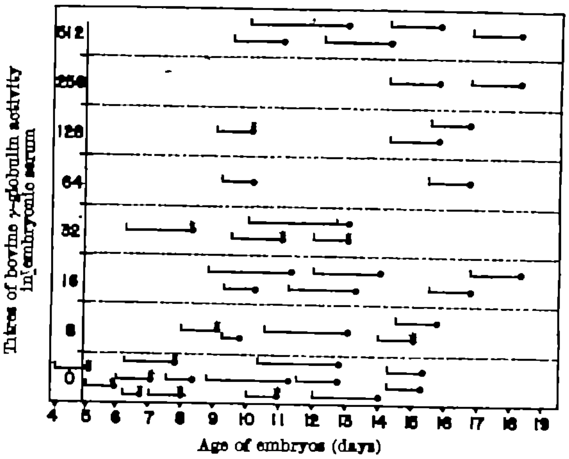

Fig. 1. Short vertical lines indicate when bovine γ-globulin was injected into the yolk sac. Black circles show when embryos were bled or extracted. * indicates pools of two or more embryos

positive and negative results were common. We have reason to believe that negative tests are obtained when the injected protein solution flows to regions of the yolk sac where it is not in contact with the yolk sac membrane. Chicks at sixteen–twenty days of incubation invariably showed bovine protein activity in their serum. These results agree rather closely with those on the uptake of antibody from he yolk. According to Brandly *et al.*[3], Dzierzgowski 1901) found that diphtheria antitoxin may pass from the yolk into the embryo "during the first 10 days" of incubation. Antibody which neutralizes the virus of infectious bronchitis of the chicken first appears in the serum of ten-day embryos[4]. Non-agglutinating antibodies for *Salmonella pullorum* were found on the eleventh day (younger embryos were not tested), but agglutinating antibodies were not detectable until the fifteenth–seventeenth days[5]. Neutralizing antibodies for Newcastle disease virus were detectable in the serum between twelve and fifteen days of incubation[3].

Brambell *et al.*[6] injected antisera produced in the pigeon and in a number of mammals into the yolk sacs of chicks at the sixth and eighth days of incubation and were able to detect only the pigeon antibodies in the circulation. It is not stated explicitly when the chicks were bled, but we infer this was done after hatching. If this is true, their results do not necessarily conflict with ours, since the mammalian antibodies may be cleared from the serum within eight–ten days, as are heterologous antibodies in the rabbit[7].

## Reaction of Alloxan with Ascorbic Acid

It has been reported from this laboratory[1] that, although acetoacetate alone causes an increase in the susceptibility to alloxan diabetes in rabbits, the product prepared by condensing acetoacetate with glucose (namely, 2-tetrahydroxy butyl, 5-methyl, 4-carboxy furan), in the form of its sodium salt, when injected intraperitoneally or intravenously in rats and rabbits in the proportion of 1·5 : 1 with alloxan or even less, can prevent alloxan diabetes[2]. It has also recently been shown by Nath and Bhattathiry (unpublished results) that 1 : 2 dienol glucose, which is liberated from this condensation product on hydrolysis, reacts with alloxan.

West and Rinehart[3] observed that ascorbic acid, another endiol compound, reacts with ninhydrin to give rise to hydrindantin and dehydroascorbic acid, which then loses a molecule of carbon dioxide, presumably through decarboxylation. Since alloxan is structurally similar to ninhydrin and because alloxan reacts with the endiol glucose, attempts were therefore made to see if a similar reaction could also be detected between ascorbic acid and alloxan, and if so what were the products of such reaction.

Vitamin C and alloxan in molecular proportions of 1 : 1 and 1 : 2 in phosphate buffer *p*H 7·2 were allowed to react at 30°, the mixture being shaken constantly. Blank experiments with vitamin C alone were conducted under identical conditions. The vitamin C content of the mixture as well as in aliquot parts was determined from time to time by the modified titrimetric method of Bessey[4].

Dehydroascorbic acid formed during the reaction was also determined according to the method of Roe and Keuther[5], and whether a portion of it was lost due to its further transformation to something else was also calculated after the reaction had gone on for 30 min. The results are shown in Table 1.

It was observed by West and Rinehart[3] that dehydroascorbic acid formed during the reaction of ascorbic acid with ninhydrin undergoes decarboxylation, presumably through the hydrolysis of its lactone bridge and subsequent loss of carbon dioxide and production of *l*-xylosone. Attempts were therefore made to find out if the loss of dehydroascorbic acid in this reaction can also be accounted for through its further transformation as above and the liberation of carbon dioxide.

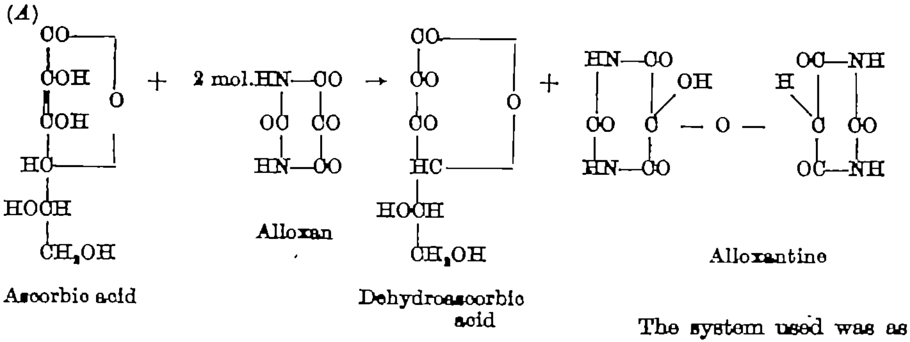
The gas evolved in the reaction between ascorbic acid and alloxan was also detected as carbon dioxide, which was estimated quantitatively by using 100 times the quantity of the reacting substances used in the above experiment. Carbon dioxide was estimated by absorption in a standard solution of potassium hydroxide by the usual method. In the first experiment, when 88 mgm. of ascorbic acid was allowed to react with an equimolar quantity of alloxan (namely, 71 mgm.), dehydroascorbic acid lost was found to be 11·6 mgm. and carbon dioxide evolved 2·57 mgm.; and in the second experiment, when the molar proportion of the constituents was 1 : 2, the amount of dehydroascorbic acid lost was 22·5 mgm. and carbon dioxide evolved 4·60 mgm.

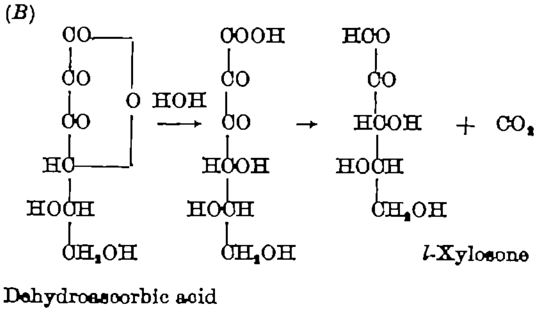
22·5 mgm. of dehydroascorbic acid on decarboxylation should yield 5·5 mgm. of carbon dioxide, which

Table 1

| No. of reactions | Contents of reaction mixture (10 c.c.) | Ascorbic acid (mgm./10 c.c.) after : | | | | Total ascorbic acid (including dehydroascorbic acid calculated as ascorbic acid) after 30 min. (mgm./10 c.c.) | Dehydroascorbic acid lost during 30 min. (mgm./10 c.c.) |
|---|---|---|---|---|---|---|---|
| | | 0 | 2 | 15 | 30 min. | | |
| 8 | Ascorbic acid, 0·88 mgm., and alloxan, 0·71 mgm. (1 : 1 mol. prop.) | 0·88 | 0·53±0·01 | 0·35±0 | 0·0 | 0·76±0·01 | 0·12 |
| 8 | Ascorbic acid, 0·88 mgm., and alloxan, 1·42 mgm. (1 : 2 mol. prop.) | 0·88 | 0·44±0·09 | 0·20±0 | 0·0 | 0·68±0·01 | 0·20 |
| 8 | Ascorbic acid only, 0·88 mgm. | 0·88 | 0·76±0·09 | 0·68±0·01 | 0·54±0·12 | 0·66±0·01 | 0·02 |

is only 0·9 mgm. higher than the observed value. It is also evident from the results that when one molecule of ascorbic acid is allowed to react with two molecules of alloxan, the loss of dehydroascorbic acid and liberation of carbon dioxide is almost double that when the molar proportion is 1 : 1, thus suggesting the possibility of one molecule of ascorbic acid combining with two molecules of alloxan, as with ninhydrin. The reaction can be represented as follows:





It is also interesting to note that although dehydroascorbic acid alone at $p$H 7·2 for 30 min. at 40° C. does not give any indication of further breakdown and liberation of carbon dioxide, it can do so during the course of this reaction.

Further work on the mechanism of this reaction is in progress.

It has been shown by Bailey *et al.*[6], Brückmann and Wertheimer[7] and others that alloxantin, unlike alloxanic acid, which is formed from the reaction of an endiol glucose with alloxan, is highly diabetogenic, thus accounting for the observation of Levey and Suter[8], who did not find any prevention of alloxan diabetes by ascorbic acid. This gives additional support for the nature of the reaction indicated above.

## Effect of Thioctic Acid on Glucose Oxidation by Liver Slices

STUDIES on the metabolism of $^{14}$C-glucose by live slices usually show a low incorporation of the lab into the expired carbon dioxide. Other tissues, whe studied *in vitro*, show a glucose respiratory quotien in the vicinity of 0·8, whereas when glucose is fe to intact animals it approaches the theoretical.

In the course of studies on the effect of insuli on the metabolism c liver slices, the effect c several coenzymes on th incorporation of labe from $^{14}$C-glucose, $^{14}$C-2 pyruvate and $^{14}$C-1-acetate into expired carbo dioxide has been investigated. Of the coenzyme studied, only thiocti acid has so far bee shown to have any influence on the oxidation of these substrates

The system used was as follows. All incubation were carried out for 1 hr. in Warburg vessels at 37° C. shaking-rate 96, amplitude 4 cm. Carbon dioxid was collected on a filter-paper spill soaked in potassium hydroxide in the centre well, and the reactio stopped by 0·3 ml. of 0·3 $N$ hydrochloric acid tippe from a side-arm, followed by 30 min. further shakin to absorb the released carbon dioxide. The syster consisted of: liver slices (paired throughout), tota dry weight 45–50 mgm.; Krebs–Ringer phosphat buffer $p$H 7·4; gas phase, oxygen 2 ml.; glucose 2 mgm., or pyruvate, 2 mgm., or acetate, 2 mgm. 0·04 µc. of the corresponding isotope was added t each vessel. Where required, 40 µgm. thioctic aci was added.

After incubation, the filter papers were remove and the potassium carbonate formed eluted by washing each four times in carbon dioxide-free distille water. The centre well was then washed out, th washings combined, carrier potassium carbonat (1 ml. of 0·01 $M$) added and the carbonate wa precipitated by the addition of excess bariur chloride. The precipitate was washed twice wit carbon dioxide-free distilled water, and then twic with acetone, plated, dried and counted usin a windowless tube. The results are shown in Table 1.

From these results it is seen that the presence of thioctic acid increased the incorporation of label from $^{14}$C-glucose, had little effect on $^{14}$C-2-pyruvate and decreased the incorporation from $^{14}$C-1-acetate, presumably by dilution with acetyl coenzyme A

Table 1. TOTAL COUNTS/MIN./MGM. DRIED-WEIGHT LIVER

| Exp. | $^{14}$C-Glucose Control | $^{14}$C-Glucose Plus thioctic acid | $^{14}$C-2-Pyruvate Control | $^{14}$C-2-Pyruvate Plus thioctic acid | $^{14}$C-1-Acetate Control | $^{14}$C-1-Acetate Plus thioctic acid |
|---|---|---|---|---|---|---|
| 1 | 10·4 | 23·8 | 133·2 | 142·8 | 118 1 | 94·8 |
| 2 | 21·3 | 26·2 | 404 | 419 | 161 | 116·5 |
| 3 | 23·5 | 34·6 | 591 | 552 | 261 | 166 |
| 4 | 26·2 | 34·1 | 557 | 564 | 238 | 171 |
| 5 | 19·7 | 23·6 | | | | |
| 6 | 20·8 | 24·7 | | | | |
| 7 | 26·8 | 31·6 | | | | |
| 8 | 23 2 | 31·7 | | | | |

For glucose $n = 7$, $T = 6·02$; hence $p > 0·01$; acetate $n = 3$, $T = 4·12$; hence $p < 0·05$.

rom non-labelled sources. It is thus concluded that in liver-slice experiments more favourable conditions for glucose oxidation are produced by the addition of thioctic acid to the buffer and, conversely, in such xperiments there is normally some difficulty in the decarboxylation of pyruvic acid, although action of he coenzyme at another point in the metabolic pathway cannot be excluded.

We thank the Australian National Health and Medical Research Council for financial support and Eli Lilly and Co. for support and a gift of thioctic acid.

## Inhibition of Acyl Trypsins by Human Serum

THERE is in blood a relatively high concentration of a specific trypsin inhibitor, the nature and identity of which are not fully established. In the presence of salts, it seems to form a stable stoichiometric addition complex with the enzyme, which is practically undissociated and enzymatically inactive[1]. Similar complexes also prevail between the enzyme and a score of other natural inhibitors, whereby, in the case of ovomucoid, complex formation can be largely prevented by chemical modification of trypsin[2,3]. Thus it was recently shown that the trypsin–ovomucoid complex has a dissociation constant $K_1 = 5 \cdot 8 \times 10^{-9}$ *M*, whereas acetylated trypsin is inhibited to a much lesser degree, the dissociation constant being higher[3] by a factor of about $10^3$.

In view of the reported use of trypsin in the intravenous treatment of inflammations and embolisms[4,5], it appeared of interest to compare the resistance of various acylated trypsins[6] to the inhibition by human serum. Inhibition was determined by measuring the activity of a constant amount of crystalline native trypsin or its acylated derivatives (0·06 mgm. per total digestion volume of 7 ml., using casein as substrate) in the presence of increasing concentrations of serum. A few typical curves are presented in Fig. 1. In the case of trypsin, the activity decreases linearly with the increase of serum concentration up to about $3 \times 10^{-3}$ ml. of serum per ml. of digestion mixture. This is the behaviour expected when a stable and inactive addition complex is formed between the enzyme and the inhibitor contained in the serum. By extrapolation of the straight portion of the curve, the stoichiometric equivalence point between enzyme and inhibitor can be established, the dissociation constant of the addition complex being then calculated from the residual tryptic activity at that point. For trypsin, the calculated value is $K = 2 \cdot 2 \times 10^{-9}$ *M*. Acetyl trypsin, in contrast to its behaviour towards ovomucoid, is still strongly inhibited (dissociation constant $K = 5 \cdot 2 \times 10^{-9}$ *M*), but for the other derivatives the inhibition decreases in the order: propionyl trypsin ($K = 1 \cdot 5 \times 10^{-8}$ *M*), butyryl trypsin ($K = 1 \cdot 1 \times 10^{-7}$ *M*), itaconyl trypsin ($K = 1 \cdot 4 \times 10^{-7}$ *M*) and citraconyl trypsin ($K = 1 \cdot 5 \times 10^{-7}$ *M*). From Fig. 1 it can be seen that there is a good agreement between the experimental points and the curves calculated from the observed dissociation constants.

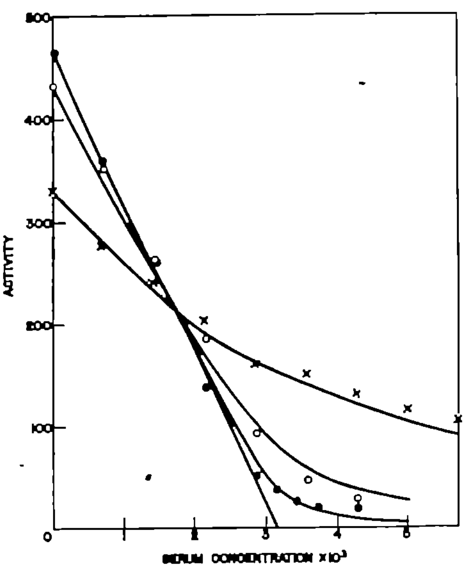

Fig. 1. Relative tryptic activities in presence of increasing concentrations of human serum. Enzyme: ●, trypsin; ○, propionyl trypsin; ×, citraconyl trypsin

The proteolytic activity of the acylated enzymes is slightly lower than that of the native enzyme, but is of the same order of magnitude. The actual decrease in activity depends on the nature of the acyl residue, as well as on the substrate with which it is measured[6]. The regular series of increasing dissociation constants of the enzyme-inhibitor complexes from acetyl- to citraconyl-trypsin follows clearly the increasing molecular volume of the acyl substituent. Thus it would appear that the increased resistance of acyl trypsins towards inhibition is not due to the blocking of the amino-groups, which were claimed to be essential for inhibition of ovomucoid[3], but can be more readily explained on the basis of steric hindrance. This steric hindrance may be of significance in explaining the mechanism of the inhibition of trypsin, as no effects of comparable magnitude ($10^3$) were observed in the action of acyl trypsins on various substrates[6].

Trypsin acts also on other components of blood. Thus its clinical use is being justified by its direct fibrinolytic activity as well as by its activation of the fibrinolytic system of the blood. Large concentrations of enzyme act also preventively, by the preferential digestion of fibrinogen, which has a high content of lysine and arginine residues, whereas the other globular proteins of the blood are relatively resistant to tryptic action, at least in the native state[4,5]. It is significant, however, that when trypsin is injected rapidly into the blood stream, it causes immediate death of experimental animals by giving rise to extensive local blood clotting[6,7]. Successful trypsin therapy seems to depend, therefore, to a great degree on a very slow rate of injection, maintaining at all times a delicate balance between the fibrinolytic and the blood-clotting activities of the enzyme. This is difficult to achieve, as large amounts of enzyme (up to 250 mgm. per rabbit were employed) are required to overcome the high concentration of serum inhibitor present. It is felt that the use of acylated trypsins, particularly the higher members of the series, would largely overcome this inconvenience, as they would maintain some of their enzymatic activity in the presence of an excess of inhibitor.

This study was carried out under the ægis of the U.S. Atomic Energy Commission and was supported by funds of the National Science Foundation.

# Characterization of a Second Pigment in Strawberries

The major pigment of the cultivated strawberry is pelargonidin-3-glucoside[1,2]. Studies reported in 1951 to the National Preservers Association showed that commercial varieties Marshall, Brightmore, Sovereign and Shasta contained a second anthocyanin in low concentration. We now present evidence that the pigment is cyanidin-3-glucoside.

The pigments were isolated by precipitation from *n*-butanol as their hydrochlorides[1]. Enrichment in the minor pigment was effected by adsorption on neutral aluminium oxide, using water as solvent. Complete separation was made on a cellulose column with a mixture of *n*-butanol and 2 *N* hydrochloric acid[3]. After concentration of the effluent under vacuum, the hydrochloride was precipitated, purified as the picrate and reconverted to the hydrochloride.

The aglucones of the pigment and of cyanidin-3-5-glucoside, from red roses, were prepared by hydrolysis with 5 *N* hydrochloric acid. These were chromatographed on paper, using butanol – 2 *N* hydrochloric acid[3]. The $R_F$ values were 0·64 and 0·64 respectively. The absorption spectrum of the aglucone was identical with that of cyanidin, in 0·001 *M* hydrochloric acid in ethanol.

The unknown anthocyanin was chromatographed together with chrysanthemin (cyanidin-3-glucoside). The observed $R_F$ values in a butanol/acetic acid/water solvent were 0·32 for both. $R_F$ values of cyanidin-3-glucoside in this solvent have been reported as 0·395 [2], 0·33 [3] and 0·30 [4]. The addition of sodium carbonate to the solution of the unknown pigment produced a blue colour, identical with that given by a crimson carnation extract[5]. A positive reaction with iron was also noted.

The unknown sugar was chromatographed with glucose and with galactose, and gave $R_F$ values in phenol/water and butanol/acetic acid/water identical with glucose. In a 2-day chromatogram with ethyl acetate/acetic acid/water[6], the unknown co-chromatographed with glucose and not with galactose. An osazone prepared from a paper eluate had the crystalline form of glucosazone.

The mono-glucosidic nature of the pigment was evident by its $R_F$ value, intermediate between cyanidin and cyanidin-3-5-diglucoside[3].

In all varieties tested, the evidence indicates the pigment is a mono-glycoside and the aglucone cyanidin. In the Shasta and Marshall varieties, the sugar moiety appears to be glucose.

# 1:8-Dimethyldibenzothiophen in a Kuwait Mineral Oil Fraction

During examination of a fraction of a Kuwait (Middle East) mineral oil, I isolated, some time ago, a small amount of a colourless crystalline substance of melting point 152–153° which appeared, from its elementary analysis and ultra-violet absorption spectrum[1], to be a dimethyldibenzothiophen or its equivalent (found: C, 79·2; H, 6·3; S, 14·3; calc. for $C_{14}H_{12}S$: C, 79·2; H, 5·7; S, 15·1 per cent). $\lambda_{max.}$ 238, 257, 265, 273, 283, inflex. 303, 313, 327 mμ (log ε, 4·66, 4·09, 3·97, 3·83, 3·88, (2·16), 2·39, 2·52). The substance formed an unstable orange-yellow picrate of melting point 129–130° (found: N, 9·9; calc. for $C_{14}H_{12}S.C_6H_3O_7N_3$: N, 9·5 per cent) and a yellow *s*-trinitrobenzene complex of melting point 154–155° (found: N, 9·5; $C_{14}H_{12}S.C_6H_3O_6N_3$ requires N, 9·8 per cent), but could not be desulphurized with Raney nickel in boiling ethanol[2]. In this it resembled 1-methyldibenzothiophen, which Mr. J. R. Crowder in this laboratory was unable to desulphurize with Raney nickel in ethanol, although dibenzothiophen itself was converted to diphenyl in 50 per cent yield (compare Gilman and Esmay[3]). This suggested the presence of a substituent in a position flanking the sulphur atom, but with the very small amount of material available it was impracticable at the time to elucidate the structure of the compound completely. It has now been identified, by mixed melting point, as the then unknown 1:8-dimethyldibenzothiophen (m.p. 153–154°) which Kruber and Raeithel have recently isolated from a coal tar fraction[4]. These authors were likewise unable to desulphurize this compound, and also noted the formation of an unstable picrate of melting point 130–131°. I am grateful to Dr. Kruber for furnishing me with a specimen of the pure compound for mixed melting point determination. So far as I am aware, this is the first derivative of dibenzothiophen to be isolated from a mineral oil source.

The starting material for this investigation was a fraction, boiling range 330–350°, of a Kuwait crude oil. This had been obtained by distillation under reduced pressure and was extracted with furfural[5] at room temperature, and the aromatic concentrate so produced treated with picric acid in ethanol. The bright red picrate, after several crystallizations from hanol, was decomposed with sodium hydroxide and e resulting oil chromatographed on alumina. Elu- on with petroleum ether containing increasing roportions of benzene afforded fractions from which : 8-dimethyldibenzothiophen crystallized at − 70°. he crude material was purified by crystallization om ethanol and from *cyclo*hexane.

This work was supported by a grant from the ledical Research Council. I am indebted to Prof. . Morton, of the University of Birmingham, for pplying the oil fraction for this investigation, and Dr. J. W. Cook for his interest in its progress. icroanalyses were carried out by Mr. J. M. L. ameron and Miss M. Christie.

## Nucleophilic Substitution in Vinylic Halides

NUCLEOPHILIC substitution of a halogen atom lirectly attached to a double bond, as in the vinyl nd phenyl halides, does not readily take place[1–3]. Nevertheless, cases of substitution in vinylic halides re recorded in the literature[4], and facile substitution as been reported for compounds containing electron-withdrawing substituents in the β-position with espect to the halogen[5]. An obvious analogy exists ith aromatic systems in which, as has been demonstrated by numerous experiments, nucleophilic substitution occurs readily only when electron-withdrawing groups are present at suitable positions in he ring.

In vinylic halides which can exist in geometrical someric forms, the steric course of substitution is f special interest since information about the geometry of the transition state can, in principle, be btained. We have examined the products and inetics of substitution in the ethyl-β-chlorocrotonates, the configurations of which are known[6].

Both forms readily underwent bimolecular reaction, n ethanol solvent, with thioethoxide, thiophenoxide, thoxide and phenoxide ions. An examination of roducts showed that with ethoxide ions or phenoxide ons the same product was obtained from both chloroesters. With thioethoxide ions, however, two products were obtained, their relative amounts depending on which chloroester was used. These two products, which we will call the higher boiling-point (and lower boiling-point) isomers, had very similar ultra-violet spectra and both gave acetoacetic ester on mild treatment with acid. All the evidence indicated that they were the isomeric ethyl β-thioethoxycrotonates. Essentially similar results were obtained with thiophenoxide ions as nucleophilic reagent. It was found that with appropriate precautions and under conditions in which isomerization of factors and products was shown not to occur, the products of reaction could be isolated in about 90 per cent yield. The results are illustrated in Table 1; kinetic data refer to solutions of concentrations approximately $M/20$.

A comparison of the infra-red spectra of the thioethoxy-esters with those of the chloro-esters showed that, although no unequivocal assignment of the bands could be made, the spectra in the range 600–1,700 cm.$^{-1}$ were best interpreted on the assumption that the lower boiling-point and higher boiling-point thioethoxy-esters had the *cis* and *trans* configurations respectively. Examination of the products obtained by treatment of the thioethoxy-esters with Raney nickel led to the same conclusion. From the lower boiling-point isomer we isolated, after cautious hydrolysis of the products of the reaction, *cis*-crotonic acid in about 30 per cent yield; the higher boiling-point isomer, under the same conditions, gave *trans*-crotonic acid in similar yield. On the basis of this assignment, it is seen that the reactions proceed largely, though not completely, with retention of geometrical configuration.

The transition state in substitution at a vinylic centre has been discussed by Bunnett[2] and Gold[3]. The most acceptable model for the present case is that in which the valency bonds at the carbon centre undergoing substitution become, or tend to become, tetrahedrally arranged. Since an extra *p*-orbital is required to form the $sp^3$ hybrids, the double bond is lost in the transition state and the carbon atom adjacent to the centre of substitution acquires a negative charge. On this view, and assuming that no rotation occurs in the transition state, substitution should proceed, in a synchronous process, that is, in the absence of a definite intermediate adduct, with retention of geometrical configuration and should be enormously facilitated in those molecules containing a group capable of delocalizing the negative charge formed in the transition state.

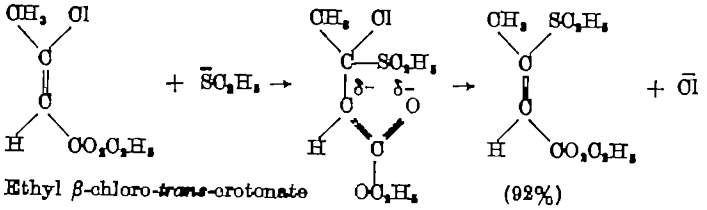
It is clearly possible to extend this formulation to include the existence of an intermediate of considerable stability. The longer the life of such an intermediate the greater will be the degree of isomerization produced by free rotation about the single bond which in the intermediate replaces the double bond of the original compound. The reactions of the ethyl β-chlorocrotonates with thioethoxide ions result in predominant retention of geometrical configuration and are best considered, therefore, as proceeding through a short-lived intermediate :

Table 1

| Compound | Nucleophilic reagent | $T$ ° C. | $k_2$ | $E$ | $\log_{10} B$ | Products |
|---|---|---|---|---|---|---|
| Ethyl β-chloro-*trans*-crotonate* | $\bar{O}CH_2CH_3$ | 0 | 0·065 | 19·2 | 14·2 | Ethyl β-ethoxycrotonate (m.p. 30·2° C) |
| ,, | $\bar{S}CH_2CH_3$ | 0 | 0·336 | 14·5 | 11·2 | 8 per cent lower b.p. isomer<br>92 per cent higher b.p. isomer |
| Ethyl β-chloro-*cis*-crotonate | $\bar{O}CH_2CH_3$ | 0 | 0·26 | 17·0 | 13·0 | Ethyl β-ethoxycrotonate (m.p. 30·2° C.) |
| ,, | $\bar{S}CH_2CH_3$ | 0 | 0·148 | 14·1 | 10·5 | 81 per cent lower b.p. isomer<br>19 per cent higher b.p. isomer |
| ,, | $\bar{S}CH_2CH_3$ | 78 | — | — | — | 87 per cent lower b.p. isomer<br>13 per cent higher b.p. isomer |

$k_2$ and $E$ are expressed in gm.mole.$^{-1}$ min.$^{-1}$ and kcal.mole$^{-1}$.

* As in the parent compounds, *cis* and *trans* refer to the configuration of the methyl and carbethoxy groups.



From studies on the corresponding unsubstituted compounds, the carbethoxy group was found to increase reactivity by a factor of about $10^4$. This large effect can be understood on the formulation given, since, as Bunnett[2] has pointed out, one of the reasons for the inertness of simple vinylic halides may well be that the carbon atom adjacent to the centre of substitution does not readily accept a negative charge.

The reactions with ethoxide ions in which only one product was isolated whichever chloro-ester was used may involve an intermediate of longer life; or alternatively, the isomer which was not found may be unstable under the experimental conditions. Since all attempts to prepare this isomer failed, we are, at the moment, unable to distinguish between these possibilities.

We thank Profs. E. D. Hughes and C. K. Ingold for their help and encouragement, and Dr. P. B. D. de la Mare, Dr. E. S. Graham and Mr. T. M. Dunn for much valuable discussion. Thanks are also due to Dr. D. J. Millen and Mr. D. Watson for measurements of the infra-red spectra and for valuable discussion, and to Mr. D. V. Banthorpe for carrying out the experiments with Raney nickel.

## A Generalization of the Concept of Acid-Strength and Acidity

At the present time it is still difficult to compare the strengths of acids dissolved in different solvents either on an experimental or a theoretical basis. The acidity constant $K_a$ as defined by Brønsted is merely a measure of the strength of the acid in the given solvent. The acidity-functions as proposed by Hammett[1] and others[2] give only experimental means of comparing the acidity of various solutions.

We suggest that Gurney's idea[3] of an energy of proton-transfer enables one to define a universal acid-strength function which has a clear physical meaning. According to Gurney, the probability of a proton-transfer from an acid molecule to a solvent molecule is proportional to exp $(-J/kT)$, where $J$ is the energy of the proton-transfer, given by:

$$J = -kT \cdot \lg K_a + kT \cdot \lg M \qquad (1)$$

where $M$ is the number of moles c solute in 1,000 gm. of solvent. If w call the energy of proton-transfer fo the solvent molecule itself (autoprotolysis) $J_\sigma$, any molecule for which $J > J$ will not behave like an acid in the give solvent. On the other hand, any molecule for which $J < 0$ will dissociate entirely in the given solvent and will be strong acid. Under these conditions, the functio

$$X = \frac{J_\sigma - J}{J_\sigma} = \frac{\log K_\sigma/K}{\log K_\sigma} = \log_{K\sigma} K\sigma/K \qquad (2$$

is a universal acid-strength function, tending toward 1 when $J$ tends towards 0 (strong acid) and tendin towards 0 when $J$ tends to $J_\sigma$ (very weak acid). (In the preceding formula, $K_\sigma = k_\sigma/M^2$ and $K = K_a/M$, where $k_\sigma$ is the autoprotolysis constant of th solvent.)

Gurney distinguishes two parts in $J$, namely, $J_1$ which depends only on the differences between th lowest quantum energy-levels of the particles befor and after the proton transfer (intrinsic proton-transfer energy), and $J_2$, which takes into account the electrostatic energy between the particles and all interaction with the solvent after the dissociation. $J_2$ is the only part of $J$ which is dependent upon temperature, through $\varepsilon$, and the study of the temperature variation of $K_a$ makes it possible to separate $J_2$ from $J_1$, as has been shown by Gurney in several examples. The lack of experimental observations of $K_a$ in different solvents and at different temperatures makes it impossible, at the present time, to decide whether Gurney's rather simple formulæ have a general validity or not. In any event, one must expect to find a function, $J_2 = J_2(\varepsilon)$, which will enable one to calculate $J_2$ in any solvent, knowing its value in one. On the other hand, it can be shown that the value of $J_1$ may easily be derived for any solvent with the help of the following two formulæ:

$$(J_1)_{AH}^{sH} = (J_1)_{AH}^{H_2O} - (J_1)_{sH}^{H_2O} + (J_1)_{sH}^{sH} \qquad (3)$$

$$(J_1)_{AH}^{sH} - (J_1)_{BH}^{sH} = (J_1)_{AH}^{s'H} - (J_1)_{BH}^{s'H} \qquad (4)$$

where $(J_1)_{AH}^{sH}$ is the intrinsic energy of proton-transfer of the molecule $AH$ in the solvent $sH$. We see thus that it may be possible not only to derive the general function $X$, but also to calculate its value for an acid in a given solvent, when its value in another solvent is known.

The use of different solvents involves also a change in the expression for the acidity of a solution. In fact, a solvent not only influences the value of $X$ for a given acid, but also for each solvent the acidity scale will be different. This can be seen immediately if one defines the acidity not by the classical $p$H but by a new function:

$$pA = \frac{pk_\sigma}{2} - p\mathrm{H} \qquad (5)$$

A neutral solution in any solvent corresponds to $pA = 0$, and $pA > 0$ defines an acid solution. In any event, the acidity scale will always be limited by the condition

$$pA < \frac{pk_\sigma}{2} - p\mathrm{H} = \frac{pK_\sigma}{2}$$

iis means that the number of protonized solvent olecules cannot be higher than the total number of lvent molecules.

## A New Detector for Vapour-Phase Partition Chromatography

Partition chromatography in the vapour phase has een developed as a valuable technique for analysis f mixtures of hydrocarbons or other volatile aterials[1,2]. Two detectors have been proposed for e with mixtures of chemically inactive substances, amely, the vapour-density bridge[1] and the thermal onductivity cell[2]. The application of an infra-red arbon dioxide detector to this problem has also een demonstrated recently. The vapour-density ridge has excellent sensitivity, but is difficult to anufacture, whereas the thermal conductivity cell relatively simple in construction but is somewhat ess sensitive. A detector has now been developed hat has a high sensitivity and is readily made in ny workshop. It also has other advantages over he other types of detector in use.

The detector is for use with hydrogen, or a gaseous ixture containing hydrogen, as a carrier gas. The nethod of detection is based on measurement of the emperature of the flame when the exit gas is burnt t a small jet. When an organic vapour is present n the gas, the flame lengthens and engulfs a thermoouple placed slightly above the normal hydrogen lame. The output from the thermocouple is fed hrough a suitable resistance network to a galvanoneter or recorder. The thermocouple can be of ron/constantan or platinum/platinum + 14 per cent hodium and is situated about 2 mm. above the jet nd enclosed in a draught-free container. The etector is extremely sensitive and has a zero stability f 1 per cent full-scale deflexion. The sensitivity vas determined using a mixture of 75 per cent ydrogen and 25 per cent nitrogen as carrier gas vith a 4-ft. column of 'Celite' impregnated with 18 per cent of paraffin. The column efficiency at 78° C. was approximately 1,000 theoretical plates, and 4 μgm. of benzene gave 2 per cent of full-scale leflexion.

Table 1

| Substance | % w/w determined | | | % w/w Actual |
|---|---|---|---|---|
| | 1 | 2 | Average | |
| Pentane | 10·5 | 10·3 | 10·4 | 12·2 |
| *Cyclo*pentane | 6·9 | 7·1 | 7·0 | 8·2 |
| Benzene | 13·4 | 13·6 | 13·5 | 12 9 |
| *Cyclo*hexane | 15 5 | 16·3 | 15·9 | 16·5 |
| *n*-Heptane | 14·6 | 13·9 | 14·2 | 13·0 |
| Methyl *cyclo*hexane | 15·5 | 16·4 | 16·0 | 15·1 |
| Toluene | 12·5 | 11·9 | 12·2 | 11 7 |
| *n*-Octane | 11·1 | 10 5 | 10·8 | 10·4 |
| Total | 100·0 | 100·0 | 100·0 | 100·0 |
| Carbon disulphide | 6·8 | 7·1 | 7·0 | 5·9 |
| Thiophen | 11·0 | 11 3 | 11·2 | 10·1 |
| *Cyclo*hexane | 13·9 | 14·4 | 14·1 | 15 1 |
| *n*-Heptane | 18·1 | 17·5 | 17·8 | 19·8 |
| Methyl *cyclo*hexane | 25 6 | 25·7 | 25·6 | 29 0 |
| 3-Methyl-thiophen | 24·6 | 24·0 | 24·3 | 20·1 |
| Total | 100 0 | 100·0 | 100·0 | 100 0 |

The detector is particularly applicable to the quantitative analysis of hydrocarbon mixtures, the area of any peak being directly proportional to the mass present, after correction for the heats of combustion of the substances. Thus the percentage by weight of any compound present can be found by expressing the area of its peak, corrected for its heat of combustion, as a percentage of the total corrected area of all the peaks. The analysis of the blend is reached without knowledge of the mass of the original charge. The results obtained for two synthetic blends of hydrocarbons are given in Table 1.

This method of detection has been found suitable for a number of volatile compounds including oxygen- and chlorine-compounds. Dichlorethane and carbon tetrachloride can be detected, but if the latter is present in quantities greater than 0·5 mgm. the flame is extinguished. This simple detector may be readily constructed in any laboratory from materials normally available. A complete vapour-phase chromatographic apparatus can therefore be constructed in a few days and quantitative chromatograms obtained with 2-mgm. samples by hand plotting from the readings on an ordinary spot galvanometer.

Details of this detector will be published elsewhere.

## Reduction of Riboflavin to a Stable Free Radical using X-Rays

The following reactions probably occur when aqueous ethanol is irradiated with X- or γ-rays[1]:

$$H_2O \rightsquigarrow H + OH \qquad (1)$$

$$H + CH_3CH_2OH \rightarrow H_2 + CH_3\dot{C}HOH \qquad (2)$$

$$\cdot OH + CH_3CH_2OH \rightarrow H_2O + CH_3\dot{C}HOH \qquad (3)$$

If a second solute is introduced into this system in a much lower concentration than the ethanol, then unless reactions 2 and 3 are very slow, the second solute will not be affected by the free radicals formed in the primary act, but will be exposed instead to the action of free hydroxyethyl radicals. Riboflavin has been subjected to the action of such radicals.

Riboflavin ($10^{-4}$ *M*) was dissolved in aqueous sulphuric acid (2 *N*) containing ethanol ($5 \times 10^{-1}$ *M*). The absorption curve of the yellow solution is shown on Fig. 1 (*A*). On irradiation of the air-free solution with a dose of 16,000 r. (190 $kV_p$ X-rays) the solution became red and showed the absorption curve *B*. On admission of air the curve changed to *C*. In a parallel experiment, an identical solution of riboflavin (curve *A*, Fig. 2) was reduced with zinc to give the stable semiquinone free radical[2] (*B*). On admission of air the solution became yellow again and the absorption curve changed to *C*.

It is clear from these experiments that riboflavin is reduced by free radicals to give the same stable semiquinone free radical as is produced by ordinary

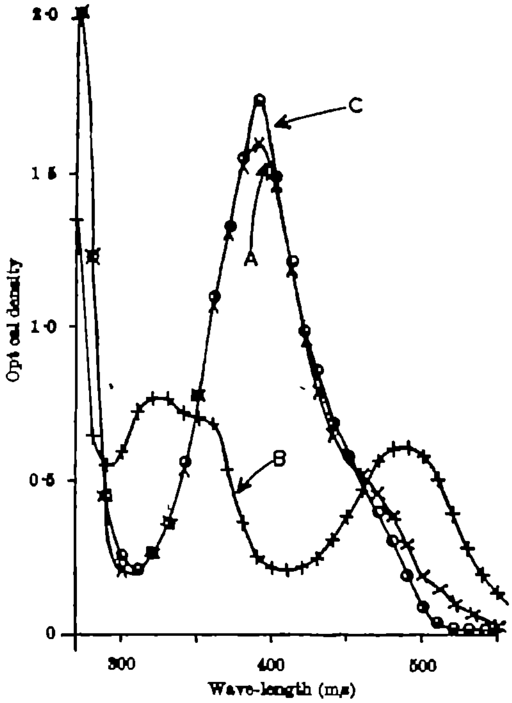

Fig. 1. Action of free radicals on riboflavin. *A* : Riboflavin control; *B* : irradiated solution; *C* : irradiated solution after admission of air

chemical reducing agents. The yield is good both in terms of radiation energy ($G = 6 \cdot 6$ molecules reduced/100 eV. absorbed) and of riboflavin reduced (95–100 per cent). The experiments may be regarded as a further demonstration that hydroxyalkyl radicals, like many other organic free radicals, have reducin properties[3], although it cannot be excluded in th case that hydrogen atoms or the secondary electro themselves may also be playing a part.

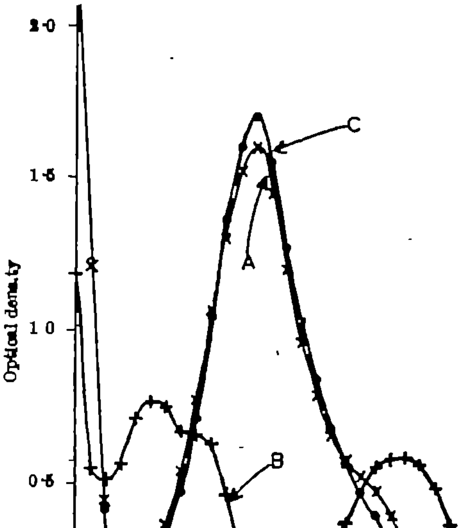

Fig. 2. Reduction of riboflavin by zinc. *A* : Riboflavin control; *B* : the half-reduced semiquinone form of riboflavin; *C* : riboflavin re-formed from the semiquinone by reaction with atmospheric oxygen

It is believed that this is the first time a stab free radical has been prepared in the liquid phase b the action of ionizing radiations.

I thank Prof. J. S. Mitchell for his interest in thi work, and Mr. A. C. Roberts for technical assistanc

## Uranium Content of Two Iron Meteorites

AN extensive series of investigations by Dalto and co-workers[1,2] using fluorimetric and radon counting techniques has indicated that the uraniu content of many iron meteorites lies in the range $20\text{–}100 \times 10^{-10}$ gm./gm. This supports an age of only a few hundred million years for some of these meteorites, and implies a distribution coefficient of only about one hundred for a very electropositive element between the silicate and metal phases of planets[3].

At the suggestion of Prof. H. C. Urey, it was decided to check the uranium content of some iron meteorites by neutron activation analysis[4] at the Argonne heavy-water pile (*CP*-5). Our results to date indicate a much lower uranium content in the two cases studied than that reported by Dalton and co-workers for the same meteorites. We do not understand the reason for the discrepancy, but feel sufficiently confident of our results to bring them to the attention of workers in the field.

Samples of two iron meteorites (Tamarugal and Thunda), approximately 1 gm. in weight, were sealed in quartz and irradiated in the middle of the reactor in a flux of $\sim 10^{13}$ n./sec./cm.$^2$ for several days. At the same time, in the same position of the pile, a 1-gm. sample of 'mock meteorite' (an evaporated solution of iron, nickel, cobalt, chromium, manganese and copper nitrates in the proportions found in iron meteorites) spiked with a known amount of uranium (about 3 μgm.) was also irradiated. After the irradiation, the outside surface (about 1 per cent) of the meteorite was dissolved in hydrochloric acid and discarded. The remainder was dissolved in the presence of about 10 mgm. of added barium carrier and about 100 c./min. of neptunium-237. Radiochemical isolation of barium and neptunium was then carried out using standard techniques. Most of the samples were dissolved in hydrochloric acid, and, after a precautionary reduction with hydrazine, the neptunium was carried on lanthanum fluoride; in two cases the meteorite was dissolved in nitric acid and, after additional oxidation with bromate, the neptunium was extracted into hexone as the first separation step. The recovery of barium was about 50 per cent as determined by the weight; that of neptunium ranged from 5 to 30 per cent as measured by the recovered α-activity.

The presence of uranium in the meteorite should result in the production of the 2·33-day neptunium-239 activity and of the fission product 12·8-day barium-140 upon exposure to neutrons. By comparison with the production of these nuclides in the spiked 'mock meteorite', the uranium content of the meteorite can be determined.

At least three irradiations on each meteorite were carried out, with the results indicated in Table 1. Although some 10–20 c./min. of radioactivity were usually found in the isolated barium, this did not decay with the characteristics of the 12·8-day barium-140 – 40-hr. lanthanum-140 chain. Thus from the barium analyses we can only set upper limits to the uranium content of the meteorites.

Table 1. ACTIVATION ANALYSIS FOR URANIUM IN IRON METEORITES

| Irradiation number | Uranium (gm.)/meteorite (gm.) (× $10^{-10}$) | | | |
|---|---|---|---|---|
| | Tamarugal* | | Thunda† | |
| | Barium-140 | Neptunium-239 | Barium-140 | Neptunium-239 |
| I | < 3·5‡ | — | — | — |
| II | <14 | < 2·1§ | — | — |
| III | < 3·5 | < 1·7 | < 3·4 | < 1·0§ |
| IV | < 7 | <45 | <11 | <20 |
| V | < 1 4 | < 4·4 | < 1·8 | Lost |

* Dalton, Paneth, Reasbeck, Thomson and Mayne (see ref. 2) quote: 30–34 × $10^{-10}$ gm. uranium/gm. in Tamarugal.

† Dalton and co-workers (see ref. 1) quote: 55 × $10^{-10}$ gm. uranium/gm. for Thunda.

‡ The limit in irradiation I was calculated from the flux as determined by the production of cobalt-60 and iron-59, and checked by gold and bismuth monitors. No mock meteorite sample was run in this irradiation.

§ These samples were dissolved under oxidizing conditions (see text); all others were dissolved under conditions designed to keep the neptunium in a state of oxidation capable of being carried by fluoride.

Small amounts of β-activity came through the neptunium chemistry also. Although it often decayed with approximately the correct half-life, we are not sure that it necessarily was neptunium-239. The limits for the uranium content calculated from this apparent neptunium-239 activity were consistent with those from the barium analyses.

On the basis of these experiments we do not feel that we have detected any uranium in iron meteorites. Because of varying conditions, the limits set in the different experiments show some scatter; more than half are lower than 5 × $10^{-10}$ gm./gm.

The comparison with the 'mock meteorite' should obviate most of the usual corrections in this type of analysis[4]. In addition, consistent limits were calculated from the approximately known flux at the irradiation positions. Since the production of cobalt-60 and iron-59 in irradiations I, II and III agreed with this flux and the accepted iron and cobalt contents of iron meteorites, there could not have been any significant self-shadowing in the sample.

We are indebted to Prof. H. C. Urey for suggesting the investigation, for supplying the samples of meteorites, and for stimulating discussions.

## Magnitude and Energy of Earthquakes

In a paper presented at a meeting of the Seismological Society of America on April 29, 1955[1], we have revised previous work[2] on the relation of earthquake magnitude $M$ to energy $E$ (in ergs). Methods formerly used to extend the magnitude scale for local earthquakes to teleseisms lead to inconsistencies, so that in effect three different magnitude scales are in use: (1) $M_L$, the magnitude originally defined by Richter[3] for local earthquakes in California as recorded on standard torsion seismometers. (2) $M_S$, that based on calculated ground amplitudes for surface waves of periods of about 20 sec. in shallow teleseisms. (3) $M_B$, that based on the amplitude/period ratio in body waves for both shallow and deep earthquakes.

Using new data, the following partly empirical equations have been set up:

$$\log E = 9{\cdot}4 + 2{\cdot}14\, M_L - 0{\cdot}054\, M_L^2$$
$$M_S - M_B = A\,(M_S - B),$$

where, originally[1], $A = 0{\cdot}4$, $B = 7$; further investigation suggests slight numerical revision.

Data are scarcely sufficient to establish a relation between $M_B$ and $M_L$. Tentative correlations are as follows:

| | | | | |
|---|---|---|---|---|
| $M_L$ | 3 | 5 | 7 | 9 |
| $M_B$ | 4·0 | 5·5 | 6·8 | 8·1 |
| $M_S$ | (2·4) | 4·7 | 6·9 | 8·7± |
| $\log E$ | 15·4 | 18·9 | 22·1 | 25·2 |

For a given observed shock $E$ is much lower than previously estimated. One main source for this decrease is the great difference in amplitudes recorded for similar earthquakes at different sites. In 1942 accelerograph data obtained by the U.S. Coast and Geodetic Survey at metropolitan locations (mostly on sedimentary rocks or alluvium) were correlated directly with seismograms at stations of the Pasadena group (mostly on basement rock). Closer study and experimentation now establish a mean amplitude ratio of about 2½ : 1 between the two groups of installations, with extreme values of about 10 : 1.

For further research on magnitude and energy we are now using $M_B$ as a general standard, reducing $M_S$ and $M_L$ to that basis so far as practicable. Tentatively,

$$\log E = 5{\cdot}8 + 2{\cdot}4\, M_B.$$

We recommend that, in publication, any systematic change in numerical magnitudes, or in routine methods for determining them, be deferred pending further study of the relation of $M_L$ to the other quantities.

We are indebted to Dr. Markus Båth, of Upsala, for communication in advance of publication of data and independent results closely parallel to some of those here reported.

## Effects of Carbon Tetrachloride on Mitosis

We have observed that carbon tetrachloride produces striking effects on *Allium cepa*, *Allium sativum* and *Zephranthus* sp. root tips. Root tips were treated for five minutes to a half-hour in carbon tetrachloride and later transferred to normal nutrient medium and fixed at various intervals from half an hour to six hours. Among the prominent changes taking place in the resting nucleus is a dissolution of the nuclear membrane and an outflow of its contents. Similar observations have been made in root tips of *Allium cepa* treated with chloroform[1] and potassium cyanide[2]. It would appear that the lipoid layer of the nuclear membrane is either dissolved or rendered weak by the chemicals, in consequence of which the nuclear contents flow out. After treatment for 15 min. with carbon tetrachloride, resting and premitotic nuclei break up. A number of chemicals are known to produce this effect, for example, urethane[3] and nitrogen mustard[4]. Perhaps the most characteristic changes brought about by carbon tetrachloride are dissolution of chromatin in the resting nucleus and disorganization of the chromosome arms in the premitotic stages, resulting in their progressively negative reaction to the Feulgen reagent.

Mitotic stages show even more striking effects. One of the commonest is the occurrence of sticky bridges in anaphase where, due to decrease in viscosity of the matrix, the distal ends of chromosomes fail to separate[5]. Bridge formation has been reported as a result of the action of chloroform[1], ethylene glycol[6] and nitrogen mustard[7], among others. Metaphase chromosomes tend to become more or less despiralized, acquire side loops and resemble the 'lampbrush' chromosomes. Levan and Wangenheim[2] have observed a similar phenomenon in onion root tips treated with potassium cyanide. Evidently the chemical affects spiralization and induces the material of the chromosome to flow out and form loops. Delayed separation of chromatids as well as chromosome fragmentation are also common in material treated with carbon tetrachloride. The spindle, too, is affected, and results in irregular and unequal segregation of chromosomes and in polyploid nuclei.

## Urinary Œstrogens in the Buffalo as measured Chemically

A knowledge of the level and the rate at which hormones are excreted is of considerable academic value for diagnostic and therapeutic purposes. The determination of œstrogen activity in the excreta is limited by the fact that these hormones are eliminated from the body in biologically active and inactive forms, thus necessitating chemical methods of measurement. The present work, consisting of tw experiments, was carried out to ascertain the lev and the rate at which urinary œstrogens are excrete in the buffalo and their chemical form.

Clean twenty-four hour specimens of urine wer collected from four buffaloes during the fourth mont of pregnancy, acidified with concentrated hydrochloric acid and boiled under reflux for 15 min then extracted four times with one-fourth volum peroxide-free ethyl ether. The extract was evaporate and the residue taken up in a minimal amoun of ethanol. Each alcoholic extract was added t 300 ml. of toluene and then fractionated into neutr and phenolic fractions. The phenolic fraction wa chromatographed and further fractionated by th use of Girard's reagent *T* and phthalic anhydride[1,2].

To determine the rate at which administere œstrogens are excreted in the urine, an ovariectomized buffalo was injected intramuscularly wit 10 mgm. of œstradiol monobenzoate in microcrystalline suspension, and 10 mgm. and 60 mgm. o œstradiol dipropionate dissolved in oil. Periods o seven days elapsed between the three different treatments, and urine samples were collected every si hours during the following 24 hr. Estimations o œstrogen were based on a physiochemical colorimetry[2].

When the urinary œstrogens were fractionated, œstradiol and œstrone were found whereas œstriol was absent. The titres found for urinary œstrogens (Table 1) were too low to have any quantitative significance. The pregnanediol titres, although incomplete, were of a very low order.

Table 1. Œstrogen and Pregnanediol Titres excreted per Litre of Urine by Pregnant Buffaloes

| Animal No. | Days pregnant | Œstrone ($\mu$gm.) | Œstradiol ($\mu$gm.) | Œstriol ($\mu$gm.) | Pregnanediol ($\mu$gm.) |
|---|---|---|---|---|---|
| 1 | 95 | 6 | 12 | 0 | 226 |
| 2 | 96 | 4 | 10 | 0 | — |
| 3 | 105 | 2 | 0 | 0 | — |
| 4 | 102 | 2 | 0 | 0 | 324 |

In the second experiment, only 0·5 per cent of the œstrogen injected in the third treatment was recovered in the urine specimen collected during the first six hours; while the first and second injections were not followed by any excretion of urinary œstrogens. Œstrous manifestations appeared after the dipropionate injections only.

Technical assistance given by Dr. Benjamin F. Stimmel, Rees-Staly Clinic Research Foundation, San Diego, California, is acknowledged. Thanks are due to the Ciba Foundation for providing hormone preparations. This work was carried out at the Agricultural Chemical Section, Giza, Egypt.

E. S. E. Hafez*

Faculty of Agriculture,
University of Cairo.

T. Attar

Agricultural Chemical Section,
Orman, Giza.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

## Monday, October 24

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 2.15 p.m.—"From Instinct through Art to Science". (1) Mr. G. V. T. Matthews: "Animal and Bird Navigation"; (2) Mr. Alan Villiers: "The Golden Age of Navigation"; (3) W./Cmdr. E. W. Anderson: "Guided Missile Navigation". (A lecture to cadets from nautical schools.)

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. F. B. Straub (Budapest): "Synthesis of Amylase in Cell-Free Systems".*

British Society for the History of Science (in the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 5.30 p.m.—Mr. E. Wilfred Taylor, F.R.S.: "The Evolution of the Divided Circle and the Dividing Engine".

## Tuesday, October 25

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Helen Spurway: "Virgin Births".*

University of London (at Bedford College, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. E. E. Evans-Pritchard: "The Position of Women in Primitive Societies and in Our Own" (Fawcett Lecture).*

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. D. R. Chick and Mr. D. P. R. Petrie: "An Electrostatic Particle Accelerator"; Dr. S. E. Hunt, Mr. D. P. R. Petrie, Mr. K. Firth and Mr. A. J. Trott: "An Electrostatic Analyser for the Absolute Measurement of Proton Energies and the Establishment of Fixed Points on the High-Voltage Scale".

University of London (in the Chemistry Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. James Sutherland: The W. P. Ker Centenary Lecture.*

University College, London (in the Electrical Engineering Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. E. H. Cooke-Yarborough: First of four lectures on "Transistor Applications". (Further Lectures on November 1, 8 and 15.)*

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Report and discussion on the 1955 meeting of the International Commission on Illumination.

Royal Aeronautical Society (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. R. J. Monaghan: "Boundary Layer Effects in Supersonic Flow".

## Tuesday, October 25—Thursday, October 27

Institution of Mechanical Engineers (joint meeting with the American Society of Mechanical Engineers, in the Great Hall of the Institution of Civil Engineers, Great George Street, London, S.W.1)—Conference on "Combustion".

## Wednesday, October 26

University of London (at the Postgraduate School of Medicine, Ducane Road, London, W.12), at 2 p.m.—Prof. N. H. Martin: "Recent Advances in the Study of the Plasma Proteins".*

Society of Chemical Industry, Food Group—Nutrition Panel (in the Rooms of the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—First meeting in the new series "Nutritional Requirements and Food Fortification".

British Association of Chemists, London Section (at the Wellcome Institute, 183 Euston Road, London, N.W.1), at 7 p.m.—Mr. E. H. Vick: "Sewerage and Sewage Purification".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion meeting on "Road Traffic—Flow and Control". Chairman: Dr. W. H. Glanville. Speakers: Sir Charles Goodeve, F.R.S.; Dr. R. J. Smeed and Colonel A. H. Young.

## Thursday, October 27

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. F. B. Straub (Budapest): "Mechanism of Active Transport of Potassium in the Human Erythrocyte".*

University of London, British Postgraduate Medical Federation (in the Beveridge Hall, Senate House, University of London, London, W.C.1), at 5.30 p.m.—Prof. Sir Wilfrid le Gros Clark, F.R.S.: "Hypothesis and Speculation in Scientific Research". (First of fifteen lectures on "The Scientific Basis of Medicine". Further Lectures on November 1, 3, 8, 10, 15, 17, 22, 24, 29; December 1, 6, 8, 13 and 15.)*

University of London (at Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Dr. A. Rényi (Budapest): "On a New Axiomatic Foundation of the Theory of Probability". (Further Lectures on November 1 and 3.)*

University of London (at Wye College, Wye, Ashford, Kent), at 8.15 p.m.—Mrs. Mary Adams: "Developments in Television".*

## Friday, October 28

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Prof. J. F. Baker and Dr. C. F. Tipper: "Notch Tensile Test".

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre, Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. S. F. Dorey, F.R.S.: "Ferrous Materials in Marine Engineering" (Andrew Laing Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Edward Salisbury, F.R.S.: "Fruit and Seed Production".

## Saturday, October 29

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. W. E. Swinton: "The Story of Animal Flight".*

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Veterinary Medicine for duty at Camden Town—The Secretary, Royal Veterinary College and Hospital (University of London), Royal College Street, London, N.W.1 (October 31).

Lecturer (with a good honours degree) in Mechanical Engineering—The Registrar, King's College, Strand, London, W.C.2 (October 31).

Instrument Engineer (corporate member of a senior Engineering Institution and with experience in the management of many types of instrument services to production and research groups) with the United Kingdom Atomic Energy Authority, Industrial Group, Dounreay Works, Caithness, to be responsible to the Instrument Manager for the maintenance on site and in a repair workshop of many types of physical and electronic instruments and to provide instrument services to production and research groups—Recruitment Officer, U.K. Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting 1150 (November 4).

Lecturer or Assistant Lecturer in Anatomy—The Registrar, The University, Manchester 13 (November 7).

Senior Lecturer and a Lecturer (with a good honours degree and preferably with teaching experience) in Physics, at the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 1 Gordon Square, London, W.C.1 (November 7)

Junior Lecturer in Entomology—The Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1 (November 10).

Supervising Geologists (3) (with a university degree, preferably with honours, or equivalent, with all geology subjects at third year standard; or equivalent qualifications) in the Department of National Development, Bureau of Mineral Resources—Geology and Geophysics, Commonwealth of Australia, to plan and supervise investigations concerning (*a*) Metalliferous mineral deposits; (*b*) radioactive mineral deposits, and (*c*) sedimentary basins—The Senior Representative, Department of National Development, Australia House, Strand, London, W.C.2 (November 11).

Lecturer and an Assistant Lecturer in the Department of Physiology, University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Senior Lecturer in Physics at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 21).

Assistant Experimental Officers (with two G.C.E. passes at advanced level in mathematics and science, if over 22 a pass degree, H.N.C. or equivalent in engineering or physics, and preferably with a general knowledge or practical experience of electronics) in the Department of Scientific and Industrial Research, Mechanical Engineering Research Laboratory, East Kilbride, near Glasgow, to assist in developing electronic devices including pick-ups, amplifiers and associated equipment for precision measuring apparatus—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.132/5A.

Master to teach Physics and Mathematics to "A" level—The Headmaster, Highgate School, London, N.6.

Principal Scientific Officer (Fuel Technology and Chemical Engineering) (with at least a second-class honours university degree or equivalent professional qualifications, and with experience in chemical engineering and fuel technology) in the East African Industrial Research Organization, Nairobi, to conduct investigations into the drying of coffee and other crops; to study fuel economy in various industries and generally to provide technical assistance—The Director of Recruitment (Overseas Service Division), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.196/463/02.

Research Assistant (honours graduate) in Chemistry—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

Supervisors (with an honours degree in either engineering or physics or equivalent qualifications and with several years industrial experience) at Dounreay Works, Caithness, for the continuous operation and control of the nuclear reactors and ancillary plant—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, near Warrington, quoting reference 1,128.

University Demonstrator in the Department of Veterinary Clinical Studies—The Secretary of the Appointments Committee of the Faculty of Medicine, Department of Experimental Medicine, University of Cambridge, Tennis Court Road, Cambridge.

# A service well worth remembering . . .

The Kodak service to scientists and technicians includes the provision of photographic plates made to special formulae.

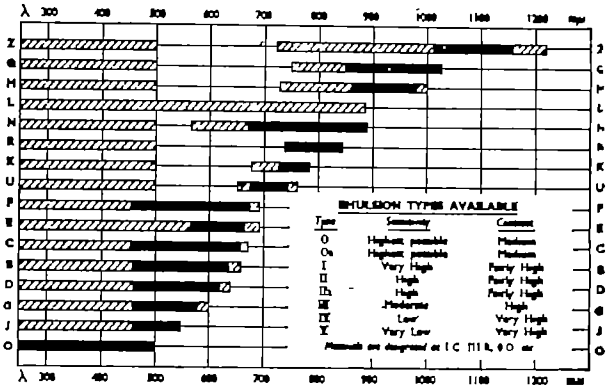
This range of 'Kodak' Scientific Plates includes 84 selected combinations of 16 colour-sensitizing classes and 8 emulsion types differing in speed and contrast. They are not normally stocked, but are supplied to special order—a service well worth remembering when no commercial plate seems to fit your requirements.

Other 'Kodak' Scientific Plates cover specific laboratory requirements:

**'Kodak' Uniform-Gamma Plate.**
Used in ultra-violet spectrography to obtain a much more uniform contrast over the spectral range 250–400mµ. Available to special order.

**'Kodak' M.R. Maximum Resolution Plate.**
Has an almost grainless emulsion and a very thin emulsion layer. Specifically produced for very high resolution photography, for graticule production, and for X-ray micrography. Stocked in ¼-plate and ½-plate sizes.

**'Kodak' Autoradiographic Plate.**
Used for tracing small amounts of radioactive substances, and to study 'tagged' atoms within the macrostructure of animal or plant tissues. Stocked in ¼-plate size.



*The chart shows the wavelength to which each of the 16 colour-sensitizing classes of 'Kodak' Scientific Plates is sensitive, and the region of special sensitivity.*

# The VIBRON

*A British achievement!*

E·I·L

The VIBRON is a new technique for measuring the very small currents which occur in nuclear physics. It is a precise electro-mechanical device which performs some 50 to 100 times better than the conventional electrometer valve. The VIBRON makes possible the development of a new range of measuring instruments. It is being applied commercially as a Nucleonic (Betaray) Thickness Gauge, as an ultra stable pH meter and as a Megohmmeter capable of measuring resistances above 1000 million megohms.

# DEVELOPMENT OF INDUSTRIAL RELATIONS IN BRITAIN

THE wave of official and unofficial strikes in Britain in the earlier months of this year, and e official warnings which have been given in the e summer regarding inflation and Britain's balance trade, have raised many questions about Britain's onomic and industrial position. Apart altogether om the issues which arise out of the development of utomation to which reference has already been made *Nature* (176, 133; 1955), the adequacy of trade nion organization has been brought into question by e inter-union disputes, and a series of further wage aims has aroused widespread misgivings as to the ssible effect on the economy of the country. The vel-headed and realistic way in which the Trade nion Congress dealt with such questions, including utomation, at Southport, has done something to store confidence and dispel the excessive sense of nfidence in our economic affairs. Prof. J. R. icks's presidential address to Section F (Economics) t the British Association meeting was also reassuring n its suggestion that British trade unions have lready learned that it is wiser to advance wage-claims on bases other than the profits of the employer, nd that the rise in money-wages since 1945 is not a ecessary consequence of full employment, but is xplicable in terms of factors peculiar to the time hrough which we are passing, particularly the dismantling of the controls and the difficulty experienced n establishing a new pattern of relative rates after he war-time disturbance.

Mr. Alec Rodger's presidential address to Section J Psychology) was also reassuring in indicating some f the resources available for dealing with the mportant problems of the effective use of man-power and human relations in industry, while Prof. . H. Richardson has contributed to a recent issue f the *Westminster Bank Review* a useful survey of he main causes and significance of the wave of fficial and unofficial strikes, in which he also considers the practicability of various remedies. Despite he economic losses and grave inconvenience to the British public caused by strikes since the middle of 954, the average annual losses from strikes during the wenty years 1935–54 amounted to less than the quivalent of one hour's work in a year by the whole ody of work-people. This favourable record is ttributed by Prof. Richardson largely to the sense f responsibility shown both by trade union leaders nd representatives of employers' associations, and heir recognition that industrial peace is vital to their wn interests and to the economic welfare of the ountry.

It is obviously important to avoid disturbing this ense of responsibility; and though complicating actors have made the settlement of wage disputes nore delicate and difficult, particularly because nions have failed to agree on a policy, Prof. Richardson emphasizes the desirability of weighing this when onsidering any changes proposed. The essential is of British industrial relations is the regulation of wages and working conditions by voluntary collective agreements, concluded after joint negotiation between trade unions and employers' organizations. This system of collective bargaining has given excellent results during the past twenty-five years; but it implies the right to strike or lock-out in the last resort. To take away those rights and prohibit the right to strike because, as Prof. Richardson shows, there have been a number of recent strikes which were called without reasonable time for conciliation and where the settlement reached could easily have been made without a stoppage, would involve setting up an authoritarian system alien to British traditions. Nor would it be certain to eliminate the risk that workers would go on strike and that the State might in consequence be forced to adopt methods of ruthless repression.

Prof. Richardson suggests drawing a distinction between strikes against the provisions of a duly negotiated and signed collective agreement, and strikes arising out of a breakdown of negotiations on the terms of a new agreement. To declare the former illegal would strengthen the trade union movement and would not restrict the basic right to strike. It would not stop unofficial strikes, but it might reduce their number.

The proposal that a strike should only take place when the decision is supported by a majority of those concerned as shown as a result of a secret ballot is, Prof. Richardson points out, a matter for the individual trade unions. It is already the rule in many unions, and could with advantage be adopted more widely; but it could not be regulated effectively by law. Similarly, the remedy for unofficial strikes really lies within the trade union movement, including measures of discipline against the ringleaders who have flouted the authority of the union, for which measures, indeed, the rules of many trade unions already provide.

Prof. Richardson sees no dramatic solution for these problems of industrial relations. Improvement depends on the cumulative effect of a many-sided attack. Structurally, the organization of some trade unions may require improvement so as to improve the contacts between the union officials and their members, just as better contacts are also needed between representatives of employers and the leaders of the unions. The Trades Union Congress has already taken some measures to restrict conflicts between rival unions; and while it may be necessary to make better provision for the formation of new unions if contact between officials and rank and file is to be vitalized, this also is a reform which must come from within. The present rigidities and complexities cannot be corrected from outside, though public opinion could play some part if better information were made available so that the issues could be understood at an early stage.

To make fuller information quickly available for public opinion to understand the issues and indicate its attitude could also help in the settlement of particular disputes; but, as Prof. Richardson observes, leaders on both sides must recognize that, though they retain the weapons of industrial warfare, those weapons should be used so rarely as to become almost obsolete if fair dealing is shown in negotiations. Moreover, on the rank and file of the trade unions rests the obligation of loyalty to their leaders and of avoiding being led astray by irresponsible agitators. Equally, the leaders must show themselves more aware of the outlook and feelings of the rank and file. It should not be impossible to provide appropriate safety-valves, consistent with the rules; these are obviously desirable to discourage the formation of splinter groups. Indeed, if the trade unions were made less rigid and liberalized, even to the extent of permitting any body of workers which genuinely desired to leave one union for another, or to form an entirely new union, to do so in an orderly constitutional manner, there might well be less dissidence and discontent even if no new unions were actually formed.

There can be no mistaking the demands which any attempt to make trade union organization less rigid and more adapted to the industrial conditions of to-day will make on rank and file as well as on officials. So far as the official is concerned, the demands will be comparable with those made on the management side of industry. Few unions have yet made any attempt to give their shop stewards, for example, the kind of economic training which would enable them to take a responsible part when negotiations at the plant-level become necessary, or to bring the shop steward into vital touch with headquarters. The demands for leadership and training are not made on one side of industry only, however; Dr. W. H. Scott has recently pointed out that greater care should be taken to see that those appointed to managerial posts possess administrative ability and a capacity for consultative leadership, and that those appointed to senior posts should be required to undergo a course of study of administration. Similar considerations apply to the trade unions.

If the excessively bureaucratic tendencies of some trade unions are to be checked, and a balance achieved between the necessary measure of centralized administration and the no less desirable development of local initiative and responsibility, similar criteria must be applied to the selection and training of full-time officials. The delegation of greater responsibility to lay representatives by the unions is essential if we are to achieve industrial democracy and eliminate the misunderstandings, strains and restrictions which have played so large a part in engendering recent disputes; but it cannot be obtained or used creatively without appropriate attitudes on the part of officials. That in itself involves a break with existing practices in recruitment, and seeking much more widely and energetically for the kind of people who are capable of discharging responsibilities in a democratic way and exercising consultative leadership.

Apart from this, as discussions on automation have recently indicated, deficiencies in management ability or a restrictive outlook on the part of the uni official can easily hinder the enjoyment by workers and the public of the benefits of advan in industrial technique or improved manager practice. The trade union official, in fact, needs creasingly an education comparable in rigour wi that required by the industrial manager if he is to me the demands made on him for judgment, admin trative ability and technical knowledge, as well for hard, constructive thinking. This is a furth reason why, as Dr. Scott pointed out, we mu encourage the development of educational institutio outside industry, as well as promote policies with it and within the unions whereby such people can produced as well as discovered.

Here, then, this need for a new outlook on th recruitment, training and promotion of the tra union official, as well as on the function and poli of the unions themselves in conditions of full emplo ment, touches on social and educational institutio generally. We must be concerned to see that th are such as to encourage the formation of personalit and further the higher level of education demande on the part of the rank and file, as well as the great demands for education and training required by th trade union official even to discharge his primar responsibilities to members of his union. Further, will not be enough for the unions to recognize the public responsibilities. The major responsibility f avoiding industrial disputes lies with management and though there is much to be done by the union within their own organizations, management still ha a primary responsibility for the improvement industrial relations, and helping to create the con ditions favourable for the trade unions to effect thei own internal reforms.

How this can be done and the way in which th two sides interact was well brought out by Mr. Ale Rodger in his address at Bristol. Of the five basi elements in a human relations policy which Si Walter Monckton emphasized at the Internationa Labour Conference last June, the provision o information and perfection of the art of com munication are pre-eminently a managerial respons ibility. Mr. Rodger asserted that it is sadly neglecte in Britain. Although we cannot hope to pla methodically and well without facts, we have muc to do here, especially in regard to vocationa guidance, before we have eliminated a serious caus of wasted man-power.

Vocational guidance, like wise selection of per sonnel, can be a potent means of avoiding friction frustration or discontent; but it is in regard t occupational training that a new outlook is mos required. Mr. Rodger points out that later school leaving is already depriving the apprentice system and the trade unions of many of the abler boys they need, through rules which are ill-adapted to the new educational system. Nor is it simply that many apprentices are not being efficiently trained. A minor man-power crisis looms ahead: for every two boys of high capacity leaving school to-day, there will be three in 1962. Fresh thinking is urgently requir on the training of young people, especially for killed trades and in the light of the implications of automation.

Mr. Rodger made no extravagant claims for the help which the psychologist or other scientist could ive. He emphasized, however, as clearly as Prof. Richardson, the importance of dealing with the difficult problem of wage differentials; and in welcoming Mr. Hugh Gaitskell's desire to see such differentials based more securely on occupational differences in skill, responsibility, effort, danger and dirt, he pointed out that in studying these and other criteria the psychologist has a substantial contribution to make. Whether he can make it, however, depends on more han his ability to make his function clear, to ormulate his questions well and to take a fuller part in industry itself. It depends equally on clear thinking about the respective functions of management, of the trade union official and of the other experts as well as about our ultimate purposes. We must have clear ideas as to their respective roles and define our objectives before we can see clearly how these contributions interlock in any one problem and what still remains to be done. There must also be clear understanding of why changes are required, and exactly what those proposed changes are intended to achieve, on the part of all concerned before we can hope to see them adopted and put into operation.

This implies a great task of education, within, as well as outside, the trade unions themselves. Much of it must be carried out by the unions, or at least with their active co-operation, if it is to be effective; but nevertheless other bodies can assist. Discussions like those at Bristol, and Prof. Richardson's paper, help to put the issues objectively and impartially before the public; and both the Press and broadcasting can play their part, not least by presenting the facts free from prejudice and distortion. Clearly the Workers' Educational Association could play an important part in promoting a re-valuation of the functions of the trade unions in the context of full employment and technological change, and developing an outlook favourable to adjustment and not to restriction; while apart from any place in such extra-mural activities, the universities, through their departments of social science, for example, can make a large contribution to the creative thinking required to develop new procedures and forms of organization.

Deeper still in this question of education lies the development of a sense of public responsibility. It is not enough for management alone to show a greater sense of responsibility towards all those employed in an industry and to the public whose interests that industry serves. The trade unions themselves must exercise a greater sense of responsibility towards the public as well as towards their own members, and must show clearly that the privileges which are theirs to-day are not used selfishly or unworthily but with a full sense of the public welfare.

That sense of responsibility was manifest at the Southport Congress at least on the part of many leaders and delegates; but it was no less clear that much has still to be done before the implications are fully understood by the rank and file, and the unions as a whole are ready to accept whatever measures may be required to prevent the abuse of power and disregard of public responsibility. The union leaders will need all the help which can be given them both in bringing home to their members the implications of the new position of their unions in the world to-day and in solving the difficult problems of union organization involved, if we are to retain the advantages of the big union in dealing with wage and like questions, and yet the understanding of local problems, whether in a particular firm or a particular area, where the small union or the shop steward has such an advantage. There is much experience which could be placed at the disposal of the unions to help them to work out their own solutions, and the studies already carried out by the Acton Society Trust or by Dr. W. H. Scott, for example, indicate that when the trade unions come to address themselves to the task of internal reform and re-organization, they can draw on concrete and impartial studies as well as an immense amount of public understanding and support.

# CHEMISTRY AND BIOLOGY OF THE NUCLEIC ACIDS

## The Nucleic Acids

Chemistry and Biology. Edited by Erwin Chargaff and J. N. Davidson. Vol. 1; pp. xi+692; 16.80 dollars. Vol. 2; pp. xi+576; 14.50 dollars. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1955.)

DURING the few years preceding the outbreak of the Second World War it was the general opinion that the chemical nature of both deoxyribonucleic acid and ribonucleic acid had been almost completely elucidated. Some anomalies, it is true, remained; but these did not seem to disturb unduly the main conclusions. Important developments, however, then occurred in the biological field. Stanley discovered that certain plant viruses were nucleoproteins containing ribonucleic acid—a result which suggested that nucleoproteins, wherever they occurred and whichever type of nucleic acid they contained, constituted biological self-reproducing units. This was followed by Caspersson's and Brachet's demonstration, the former using ultraviolet spectrophotometry and photography and the latter histochemical methods, of the widespread occurrence of ribonucleic acid in the cytoplasm of animal and plant cells and, in particular, of its high concentration in those cells in which protein synthesis could be assumed to be taking place. Finally, there came Avery's discovery, not only that the principle which transformed the rough form of Type II pneumococcus into the smooth form of Type III was a deoxyribonucleic acid, but that also this substance was specific to Type III pneumococcus. It thus became evident, first, that ribonucleic acid was much more widely distributed in Nature than had previously been thought and, secondly, that species specificity, with all its implications, might exist among the deoxyribonucleic acids of higher organisms despite the overt or tacit rejection of this idea by earlier workers.

Doubtless as a result of these developments, the past decade has witnessed a renewal of investigations, both from the chemical and biological aspects, into the nucleic acids which, if one is to judge from the bulk of literature that it has produced, have been carried out with an intensity hitherto unknown in this field. It is the object of the present work, which consists of two volumes, to give an up-to-date and detailed account of the nucleic acids in the light of these recent researches. The two volumes are devoted respectively to the chemistry and biology of the subject.

As a perusal of the first volume shows, the last word on the chemistry of the nucleic acids has not yet been spoken. Nevertheless, many substantial achievements, particularly in the development of experimental techniques, are recorded. Thus, the isolation of deoxyribonucleic acid, if not of ribonucleic acid, is now a relatively simple, if tedious, process; the application of paper chromatography, associated with the use of ultra-violet spectrophotometry, has provided a method for the determination of the bases present in both types of nucleic acid with an accuracy previously totally unattainable; and the isolation of nucleotides from hydrolysates of the nucleic acids, an operation which was so laborious and gave such uncertain results when the older chemical methods were used, can now be effected more readily and with greater certainty both by ion-exchange chromatography and by paper ionophoresis. When the use of the classical methods of organic chemistry and of specific enzymes which bring about the step-wise degradation of the nucleic acids or their hydrolysis products is combined with these newer techniques, as they have been, it is not, perhaps, surprising that some of the old conceptions of the nature and composition of these substances have been abandoned.

Nevertheless, a very substantial amount of the older work remains valid. In particular, the fundamental conception of the nucleic acids as a chain of nucleotides united together by ester linkages between the phosphoric acid group of one nucleotide and a hydroxyl group of the carbohydrate of the other still holds, as do the structures assigned to the individual nucleotides. But results with the new techniques have certainly demonstrated that the nucleotides are not combined together in equimolecular proportions, as was formerly believed and expressed in the tetranucleotide theory. They also include many other achievements, among which are the discovery, in minute amounts in the deoxyribonucleic acid from animal sources and in larger amounts in that from wheat germ, of a fifth nucleotide containing 5-methylcytosine as base; the finding that the deoxyribonucleic acid of a number of bacteriophages contains 5-hydroxymethylcytosine instead of the customary cytosine; and the precise determination of the positions of the internucleotide linkages in both ribonucleic and deoxyribonucleic acids. The question of the species specificity of the nucleic acids has, however, not yet received a definite answer. That there exist different deoxyribonucleic acids, particularly among the micro-organisms, has been abundantly proved both by chemical and biological methods. Moreover, as the results mentioned above show, the deoxyribonucleic acid from wheat germ appears to be different from that from animals. But it would, in my opinion, be taking too optimistic a view of the overall accuracy of the analytical processes employed to conclude from the later and more accurate figures obtained with animal deoxyribonucleic acids that these are species-specific. This opinion is reinforced by the evidence provided by, among others, one of the editors of this work tha the nucleic acids are not homogeneous. Should th evidence be confirmed, it will clearly considerabl diminish the value of the mass of analytical dat which has been published on the composition deoxyribonucleic acids from various sources.

Advances in the biological field, described in th second volume, represent steady progress rather tha spectacular achievements. Thus, Avery's origina discovery has been extended; the widesprea occurrence of ribonucleic acid in biological material particularly in the cytoplasm of animal cells, ha been confirmed by numerous analyses; measurements have been made, using various types of cell from different species, of the weight of deoxyribonucleic acid in single nuclei, the results being interpreted as indicating the presence of a constan amount of this substance in the nuclei of all diploid and half that amount in haploid, cells of each species and a start has been made, using the isotope-tracer method, in ascertaining the nature of the precursor used in the biosynthesis of the nucleic acids.

Dealing, as they do, with these and many othe aspects of the nucleic acids, the two volumes of thi compilation give, on the whole, a very complete and up-to-date account of the nature and occurrence of the nucleic acids and of their chemical, physicochemical and biological properties which will be invaluable to all working in this field. It will doubtless become the principal, if not the only, modern reference-book on the subject. This statement does not, however, mean that the whole work is uniformly excellent. This would not, indeed, be expected of a treatise the twenty-eight chapters of which embody the contributions of thirty-four authors. There are, in fact, many criticisms, of different degrees of importance, which might be made. Of these, I have selected three which I feel bound to make.

Owing to its size, the price of the work will render it inaccessible to individuals except through libraries. By more careful selection of the subject-matter and by the pruning of redundant material, this result could have been minimized to the benefit both of the reader and of the finances of libraries. For example, Chapter 2 is a monograph of seventy pages on ribose and deoxyribose. Most of the details which it contains belong to carbohydrate chemistry and must surely be included in the literature of that subject. It therefore seems superfluous to reproduce them here. Chapter 3, dealing with the purines and pyrimidines, is to some extent susceptible to the same criticism, but it serves better, by quoting the following sentence from it, to illustrate how far the subject-matter of the work may in places digress from the nucleic acids: "In 1943, the important discovery was made that the administration of alloxan to rabbits leads to the necrosis of the insulin-producing units of the pancreas (the β-cells of the islets of Langerhans), thereby providing a tool for the production and study of experimental diabetes".

The greater the objectivity with which a scientific treatise is written, the more valuable will it be. In my opinion, such objectivity is not always present in the discussion in Chapter 17 on the use of the Feulgen reaction for the quantitative determination of deoxyribonucleic acid in biological material. The author should have made it clear that, for obvious reasons, this reaction is never used for the estimation of deoxyribonucleic acid *in vitro*. He should also have discussed experiments which have shown that, at ny rate when one commonly used fixative is mployed, considerable quantities of nucleic acid are st from cell nuclei during the period of hydrolysis equired to produce maximum intensity of staining y this method. Instead of doing this, he is content o brush objections to one side and to regard the method as justifiable because it usually yields the desired results.

Chapter 18 is not the authoritative article which urchasers of this work are entitled to expect. The author dismisses my work with the remark: "Unfortunately many of the conclusions drawn by the Stedmans from their experimental data . . . are, in he opinion of the writer, highly questionable" without so much as mentioning the nature of the conclusions or of the data on which they were based; and this is not the author's sole lapse in propriety.

E. Stedman

## SCIENTIFIC BASIS OF MEDICINE

### Lectures on the Scientific Basis of Medicine

Vol. 2, 1952–53; pp. xi+380+29 plates. Vol. 3, 1953–54; pp. iv+398+9 plates. (British Postgraduate Medical Federation: University of London.) (London: Athlone Press, 1954. Distributed by Constable and Co., Ltd.) 35*s.* net each vol.

THESE two volumes continue the publication of the yearly series of lectures, begun in 1951, under the auspices of the British Postgraduate Medical Federation. In his preface to Vol. 2, Sir Francis Fraser, director of the Federation, explains that the topics of these lectures are selected by a committee as being ripe for presentation to an audience of young medical research workers and junior consultants and specialists. The lecturer invited to deal with each topic is a person actively engaged in furthering advance in it by original research. Sir Francis points out that the lecture syllabuses are not a mere haphazard tour around a changing scene, nor can any single annual syllabus properly be treated as an isolated entity. Each course is planned as a stage in an integrated, continuously developing survey which can only yield its full value to the student who keeps himself continuously familiar with it. It is to enable students to do this that the Federation provides these annual published volumes. Not all the lectures delivered are published; in part because accessible summaries exist, in part because their topics, though presentable in lecture form, are not yet ready for evaluation in print. Vol. 2 contains nineteen out of thirty-six lectures delivered, and Vol. 3 twenty-one out of thirty.

It is of interest to survey these volumes in the light of Sir Harold Himsworth's recent Linacre Lecture (*Brit. Med. J.*, ii, 217; 1955) on "The Integration of Medicine". They provide a partial answer to Sir Harold's plea for more comprehensive postgraduate study, and they illustrate well the difficult task of those engaged in such education to present briefly and in readily understandable form the rapidly growing and ever more specialized topics that to-day form the basis of medicine. The lectures range over chemistry, biochemistry, physics, physiology, genetics, bacteriology, virology and zoology. They are for the most part simply and interestingly written. They provide not only the junior, but also the senior postgraduate workers (whose need is almost as great) with helpful surveys of the advances in knowledge in many fields relating to medicine. It is permissible to question, however, if undergraduate medical education is now of the nature to produce more than a small proportion of young graduates sufficiently 'groundedly learned' fully to appreciate the material here offered for their understanding.

In view of Sir Harold's fear about the diminishing recruitment of medically qualified men to the non-clinical branches of medicine, it is heartening to see that, of the forty lecturers in the two volumes under review, twenty-eight are medically qualified. Moreover, a glance at the list shows that, as Sir Harold desires, they are men of authority, and no less than eleven are distinguished as Fellows of the Royal Society.

R. T. Grant

## THEORY OF JET FLOW

### Fluid Dynamics of Jets

By Prof. S. Pai. Pp. xv+227. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1954.) 37*s.* 6*d.* net.

THE theory of jet flow is a natural offspring of boundary-layer theory; but until recently it lacked, unlike its parent, the stimulus of important practical applications. During the past decade, however, the development of jet propulsion has profoundly modified the aeronautical picture, and the study of jet flow has acquired great practical significance. Jets can be used to propel aircraft, to provide lift, to assist boundary-layer control and generally to modify the aerodynamic characteristics of surfaces near which they pass or from which they emerge. Thus, there arise three main topics of interest: the flow in jets, the effects of jets on neighbouring surfaces, and the interaction of jets. Prof. S. Pai's monograph is concerned almost exclusively with the first topic, for the good reason that only the flow in jets has yet received sufficient attention to provide ready material for a book.

The book deals essentially with theoretical developments, and its appeal to the practical engineer is likely to be limited. Much of the material is not new; but it has important sections never previously published in book form, and the book is noteworthy as the first in English devoted exclusively to jet flow. Its presentation is, in the main, logical and straightforward, although occasionally the arrangement of some items is surprising. It covers very extensive ground, and therefore some important subjects are given little more than a brief mention; an initial glance at the table of contents is apt in such cases to raise unfulfilled hopes.

The first three chapters are concerned with jets of an inviscid fluid, one chapter being devoted to an incompressible fluid and two to subsonic and supersonic flow of a compressible fluid. Much of this material is classical but is none the less interesting. The remainder of the book deals with jets of a viscous fluid. The fourth chapter is concerned with laminar jet flow for both compressible and incompressible fluids, and the following two chapters deal similarly with turbulent jet flow. Here the limitations and inadequacies of mixing-length theories are fully discussed; but these theories are applied extensively in view of their success in providing useful relations of proved validity for incompressible fluids. Inadequate warning is given, however, of the difficulties in extending these theories to compressible flow.

Thus, equally plausible assumptions can lead to widely divergent results, and the available experimental data offer as yet little empirical guidance. These chapters include a brief discussion of the more important aspects of the statistical approach to turbulence and a very inadequate reference to the important topic of jet noise. An interesting chapter follows on the mixing of jets of different gases where diffusion becomes important, and the last two chapters deal with the stability of jets of incompressible and compressible fluids. The theory is presented in some detail, but more might have been made of the results. In an appendix the fundamental equations of fluid dynamics are briefly derived.

The writing lacks grace, and there is an irritating economy in the use of the definite article as well as an occasional misprint. Nevertheless, the book is clearly and honestly presented and should be welcomed by the many aeronautical scientists concerned with jet flow. A. D. YOUNG

# ENERGY FROM THE SUN

## Applied Solar Energy Research

A Directory of World Activity and Bibliography of Significant Literature. Edited by E. J. Burda. Pp. ix+298. (Stanford, Calif.: Stanford Research Institute, 1955. Published for the Association for Applied Solar Energy.) n.p.

RESEARCH on the utilization of solar energy has been greatly stimulated during recent years, and rapid developments have been made in the United States and other countries. There is an increasing realization that such applications will play an important part in the future co-ordination of world energy resources, and an Association for Applied Solar Energy has been formed at Phoenix, Arizona. As a preliminary stage in its programme to encourage research, this Association has issued the first international directory and bibliography of solar research as a record of what has been done in the past and is being attempted in the present.

This publication is much more than a mere list of references; under headings of countries, Part 1 lists the universities, other organizations and individual research workers who are engaged in solar energy activities, with brief summaries of the work in progress. Although the United States section contains more entries than all other countries together, there is evidence of an active world-wide interest in this subject. Short details are given of solar symposia that have been held since 1950, including particulars of the World Symposium on Applied Solar Energy which is to be held this November in Phoenix, Arizona.

Part 2, constituting the remainder of the volume, is a bibliography containing nearly fifteen hundred references, with short abstracts in most cases. These references are numbered and arranged in alphabetical order; and the numbers are rearranged in a cross-reference of classified subjects—for example, distillation, heaters, insolation, photo-synthesis, to give a few examples. The information is invaluable not only to those engaged in active research, but also to those commencing a study of the subject. Library facilities and staff for this publication were provided by the Stanford Research Institute under the general direction of Merritt L. Kastens, with the co-operation of Dr. Marie Telkes, of New York University.

# TECHNOLOGY OF TITANIUM

## Titanium in Industry

Technology of Structural Titanium. By Stanley Abkowitz, John J. Burke and Ralph H. Hiltz, Jr Pp. x+224. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd. 1955.) 36s. net.

THE development of the three structural metal of this scientific age—titanium, magnesium an aluminium—has not, in terms of the span of huma life, been fast. In each of these cases, from bein initially recognized in the laboratory, until equa recognition was attained in the industrial world, a period of time varying from three-quarters to rathe more than a century and a half has elapsed. Seemingly, but not paradoxically, because the metallurgica difficulties involved were very great, titanium, th first of this little group to be discovered, has take longer to acquire engineering status than the othe two. In 1789, its existence was clearly realized by th Rev. William Gregor. The metal did not, however, attain a position in engineering until the present decade. It—or more exactly, some of its alloys—was then shown to have a combination of qualities, such as low specific gravity when compared with iron; mechanical properties (up to about 300° C.) comparable with those of alloy steels; and, in a large numbe of media and in particular in sea water, a quit outstanding resistance to corrosion. These characteristics made it suitable for applications wher performance, rather than cost, was the primar consideration. This is, of course, the case in th aircraft gas-turbine field.

In a book of slightly more than two hundred pages, divided into ten chapters, the authors attempt to cover the production of the metal, its chemistry and physics, and manipulation in mill, forge and worksho of both it and of some of its many alloys. The tas they have thus undertaken is a formidable one. Their book is of necessity superficial. It is not, however, inaccurate, and indeed has merit. It contains more than twenty excellent photomicrographs and some good graphs in relation to a numbe of the mechanical properties of some of the man titanium alloys. With regard to their fatigue and creep characteristics, however, the treatment is disappointing. This is unfortunate, for it is thes qualities which are of the utmost importance in th field in which the metal and its alloys are at presen finding their greatest application. Against thi criticism, it is but fair to state that the work is, in most respects, up to date. For example, the authors disclose, as has only recently been appreciated, the unexpected but tremendous influence of hydrogen on titanium. In excess of a hundred parts per million, this gas, which markedly alters the microstructure of the metal, is deleterious. When the metal contains double this amount, a number of undesirable characteristics, for example, grave reduction in such essential engineering properties as ductility, impact and fatigue resistance, may well arise.

To conclude: anyone having a somewhat detached interest in titanium and its alloys will find this well-produced book, in spite of its relatively high cost, a worthwhile introduction to a very large subject. O the other hand, should the potential reader be alread involved in the production and/or use of titanium an its alloys for structural and/or mechanical purposes, i will often prove wanting—due to the magnitude of it scope, it inevitably lacks depth. P. L. TEED

# THE NEW SCHMIDT TELESCOPE OF THE HAMBURG OBSERVATORY

By Dr. O. HECKMANN

Director

DURING the summer months of 1954, a new Schmidt telescope was installed at the Hamburg Observatory in Bergedorf, some fifteen miles east of the city of Hamburg. The instrument was under test during the succeeding ten months, and on August 19 and 20 its dedication was celebrated by an astronomical meeting in Hamburg devoted to various matters of technique, method and programme related to the new type of telescope. The instrument was already planned in 1936, when Dr. W. Baade, of Mount Wilson Observatory, was to become director of the Hamburg Observatory, to the staff of which he had belonged during 1920–31. The instrument was tentatively designed to have an aperture of 80 cm. and a mirror of 100 cm. diameter with a focal length of 160 cm. ($f$ : 2). But Baade stayed in Pasadena because a still larger Schmidt telescope was to be put at his disposal, the 48-in. (= 120 cm.) Schmidt of Mount Palomar ($f$ : 2·5) completed after the War. The Hamburg instrument could not be realized until, in 1948, the German currency recovered. The original plans were somewhat changed by increasing the diameter of the mirror from 100 cm. to 120 cm. and the focal length from 160 cm. to 240 cm.; so its dimensions are about two-thirds of the Palomar instrument.

The design of the Hamburg instrument has been influenced by that of its larger Californian counterpart, but there are some noteworthy differences. The first is the fact that a double tube was chosen, so as to avoid flexure of a magnitude that could cause deterioration of the definition of the optical images when an objective prism of some 400 kgm. is put in front of the correcting plate. Indeed, when moving the instrument from zenithal to horizontal position the correcting plate is shifted by less than 0·1 mm., which is very satisfying. Secondly, there is an automatic temperature compensation of focus; this is provided by three rods regulating the distance of the mirror from the plate-holder but—and here is the difference from the Palomar 48-in.—using rods of approximately the same high thermal inertia as that of the mirror. In order to avoid very rapid temperature changes, the whole tube is protected by a felt cover 15 mm. thick covered with canvas. Thirdly, the mounting is of the fork type; but the fundamental idea is to have all movable parts supported exactly below their common centre of gravity. This is achieved by making the centre of gravity the centre of a sphere, part of which consists of a ground steel zone of 2 m. radius, at the base of the very heavy yoke of the fork. Fig. 1 demonstrates this better than any verbal explanation. The steel zone rests on self-adjusting oil pressure-bearings; so the adjustment of the polar axis of the instrument is carried out without working against gravity.

The instrument is moved by electrical controls into any desired position by means of 'Selsyn' motors. The two guiding telescopes can be adjusted so that their flexure relative to the main tube vanishes. They are easily accessible by means of a car which, by an electrically driven hydraulic piston, can hoist a platform with the observer. He can control all motions of the car from his seat. A hydraulic lever can be substituted for the platform when the mirror is to be taken from the instrument for aluminizing.

Whereas the mounting of the instrument was manufactured in the machine tool works of Heidenreich and Harbeck in Hamburg, the optics and the tube were made by C. Zeiss of Jena. In spite of the political tensions between the east and west of Germany, the two firms found a reasonable way for their mutual collaboration.

The mirror consists of the low-expansion glass *ZK*7, the correcting plate and the 4° prism of glass *UBK*7, which is transparent to the ultra-violet. The optical quality of the prism has not yet been investigated. The properties of the system mirror plus correcting plate are as follows: In the extremely steady air of the Zeiss laboratory, we could estimate visually that distances smaller than 0·5″ could be resolved. When used for celestial photography, unsteadiness of the air and the diffusion of light in the emulsion become of increasing influence, so that the smallest star images on the average are about 2·5″, that is, about 30μ. So we may say that the performance of the instrument is limited by the seeing conditions and not by its optical quality. The

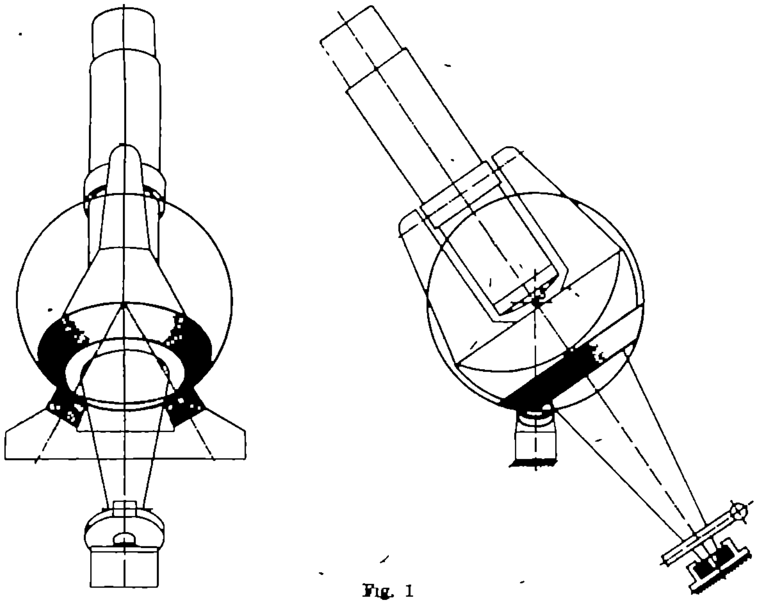

Fig. 1

square plates cover a field of 5° × 5°. If they are not thicker than 1 mm. they never break when bent to a sphere of 2·4 m. radius, as is necessary in all orthodox Schmidt telescopes not using field lenses.

As regards the observing programme with the instrument, I feel somewhat uneasy because of the wealth of problems which eventually can be undertaken; so I hesitate to say much. The most serious danger is to begin programmes which can be easily photographed but which are difficult to evaluate on account of the enormous amount of informatio afforded by a single intelligently taken photograph

We plan to work on galactic clusters, known a well as hitherto unknown. Work on variable star is also possible. Further, we are interested in th distribution and colours of extragalactic nebulæ. I addition, the objective prism makes possible a searc for several kinds of special stars. Further, shoul the number of plates threaten to overwhelm us, w shall be glad to pass on material to astronomers wh are willing to evaluate it.
